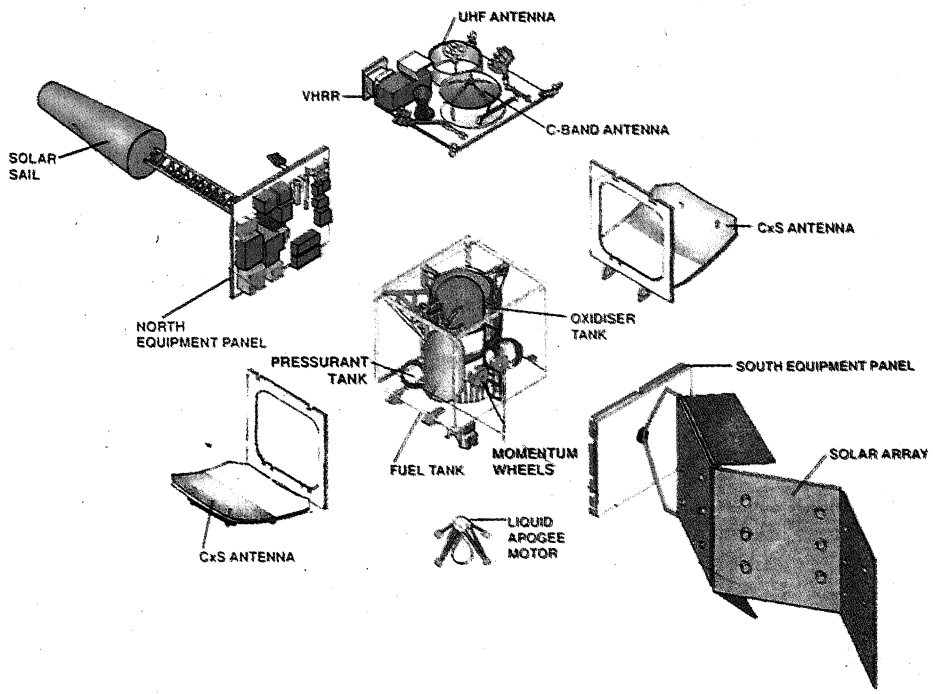
To understand how these multidimensional services are provided and what MCF's role is in controlling the satellite, it is essential to have a broad understanding of the satellite's subsystems and the orbit. A satellite can be visualized as being composed of its payload and the mainframe or a platform to operate the payload, comprising many interlinked subsystems. The payload is that part of the satellite which specifically caters to the application. For example, the communication payload on INSAT provides the necessary functional capabilities to receive a radio signal from a ground station in a specified frequency band, amplify and retransmit back to ground in a different frequency band. There are a number of subsystems which are essential for any operational spacecraft. Electric power subsystem is generally composed of solar arrays for generating power, rechargeable chemical batteries for storing power and power control electronics for load regulation. The attitude and orbit control system (AOCS) is composed of a set of attitude sensors to sense the current orientation of the body, processing electronics and set of actuators to generate control torques to orient the payload in the desired direction. The thermal subsystem provides the required thermal environment for the different components/subsystems. Active control using heaters is usually available. The propulsion subsystem provides the capability to carry out orbit transfers, orbit maintenance, and provides for attitude control torques. The subsystem directly interfacing with the mission control centre is the telemetry, tracking and command (TT&C) subsystem. The communication is in specific RF frequencies in the GHz range. The telemetry subsystem centralizes the encoding of information from all the onboard subsystems and transmits them as a telemetry signal, probably the ever-running commentary about the on-board activities. Command subsystem provides the capability for receiving, decoding and distributing commands from the ground. Turn-around ranging provides the tracking data for orbit determination.



Orbit maintenance

A geostationary satellite has a designated longitudinal position in the equatorial plane over which it is placed.

S. Rangarajan is at INSAT Master Control Facility, Department of Space, Hassan 573 201, India.

A view of the Master Control Facility, Hassan.

INSAT-2B disassembled view.

However, perturbations such as luni-solar gravitational effects, nonsphericity of the earth and solar radiation pressure cause deviations from the ideal orbit. These affect, respectively, the inclination, semimajor axis and eccentricity of the orbit. If there is any departure from the ideal geostationarity, the direction to the satellite will show a variation. Bigger antennae have a smaller beam width and hence this effect is more pronounced in them. The deviations are expressed in terms of the excursions in the latitude and the longitude of the subsatellite point (vertically below the satellite). It is MCF's responsibility to maintain the orbit such that these deviations are less than 0.1°.

For this purpose the orbit is determined by sending a set of sinusoidal tones from MCF to the satellite, modulating it on a suitable uplink carrier. The tones are turned around by the satellite on a downlink carrier. By measuring the phase difference between the transmitted and the received tones, the distance to the satellite is calculated. This, coupled with the direction information as determined from the antenna pointing angles, provides the instantaneous position in three dimensions. Similar measurements carried out several times a day are sufficient for reconstructing the orbit. From the determined orbit, it is possible to work out the optimal date and time of orbit correction manœuvres. The inclination of the orbit, which affects the latitudinal excursions, must be limited to 0.1° in case of INSAT. This calls for an out-of-plane thruster firing once in about 80 days. The propellant consumed in each of these manœuvres is about 4 kg for INSAT, which has an on-orbit mass in the range of 1000 kg. Once there is insufficient fuel for this correction, the inclination of the orbit will build up, marking the end of mission life. The control of semi-major axis and eccentricity calls for in-plane thruster firing and the fuel requirements are an order of magnitude less. However, the frequency of corrections can be as high as once in two weeks. These manœuvres are critical activities carried out with the participation of subsystem specialists on a real-time basis. A typical manœuvre operation lasts about 4 h and the user services remain unaffected.

Orbital events

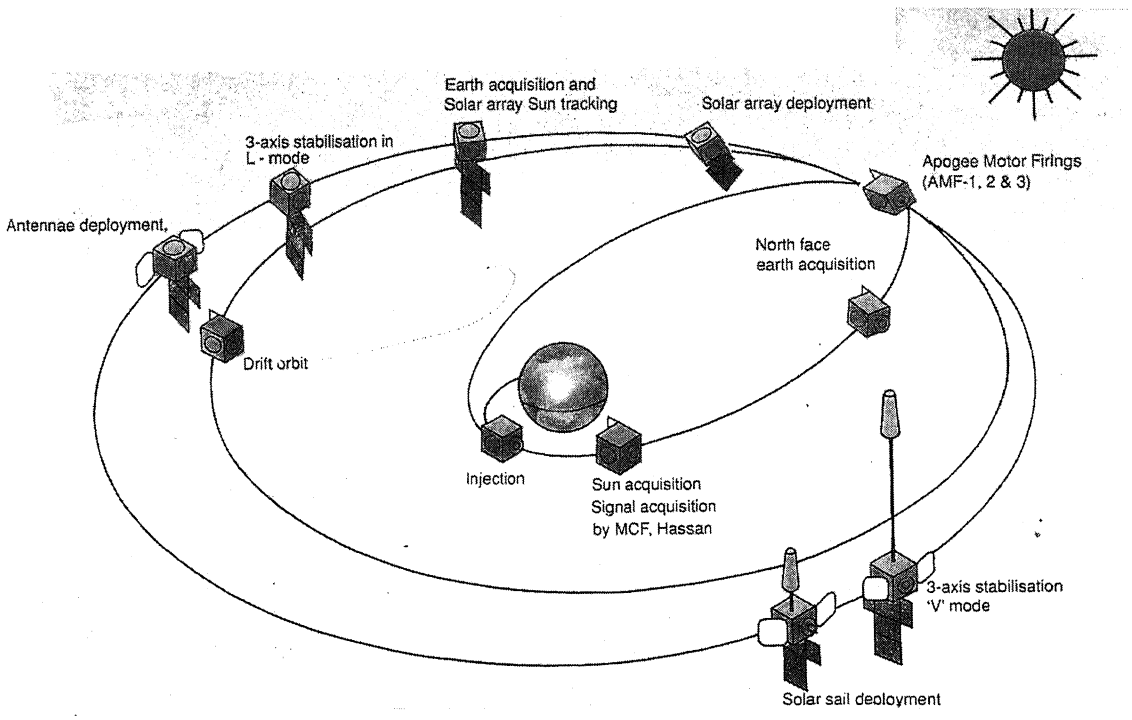
Precise orbit determination of satellite's orbit has other uses for preventive measures. If an observer views the celestial bodies from the satellite, he would naturally see them going around the satellite in various orbits, sometimes one occulting the other. Some of the orbit-related events are earth shadow, lunar shadow, sun/moon intrusion into the field of view of sensors, etc. As the evolution of the orbit is predictable to a reasonable accuracy, many of these events can be predicted well in advance and suitable actions planned. Some of the events greatly dictate the overall design of the satellite itself. For example, satellites in the geostationary orbit pass through the shadow of the earth around midnight local time for 45 days centred around the equinox. The longest eclipse is for 72 min and during this period the onboard battery supports the loads. Depending on the battery capacity, some loads may have to be shut off for the duration of the eclipse. The battery is to be charged using the solar power once the satellite comes out of eclipse and be ready for next day's eclipse. One can imagine the constraints put on the thermal subsystem of the satellite to maintain an equilibrium temperature for the critical subsystems in the absence of solar input for about an hour and to operate any heater, if at all, with tight power budget.

Link between control centre and satellite

It may be true that the design methods go on improving constantly to keep the satellite going, but still space environment is not yet completely understood to make the systems error-free. For the payload as well as the other subsystems of the satellite, it is essential to monitor the proper functioning. If ever a fault is detected, immediate correction is called for not only from the point of view of user services, but also for preventing the fault from worsening and propagating to other subsystems. For this purpose, it is essential to have knowledge of the current status of the satellite. A number of parameters pertaining to the different subsystems such as the temperature at different locations, operating status of equipment, pressure of fuel tanks, voltage, current and power consumed of selected units, angular information with respect to solar and other bodies, etc., are measured onboard and transmitted to the control centre. Some of these parameters are analog which are converted to digital data by sampling and quantizing. The sampling rates are different for different parameters. For example, temperatures which are generally slowly varying are sampled less frequently compared to attitude information, which is sampled more often.

The different parameters are multiplexed to form a composite telemetry stream. INSAT-2 satellite has about 400 analog parameters and 400 status parameters to be monitored. These are organized into a telemetry masterframe which repeats every 8 s. The slowly varying parameters occur only once in a masterframe. Each masterframe has 8 frames and each frame has 128 eight-bit words. Including the overheads required to identify the start of frame and the subframe within the masterframe, the telemetry has a bit rate of 1 kbps. As the transmission from the satellite is at a very high frequency, the telemetry data are first modulated on a subcarrier which, in turn, modulates the RF beacon. INSAT uses PSK modulation on a 32 kHz subcarrier

and PM modulation on a 4 GHz carrier. On ground, the entire sequence has to be undone, namely, receive the beacon, recover the subcarrier, obtain the bit stream, synchronize the frame, identify the words and bits, convert to engineering units, and display the data. Besides being useful for mission control, the telemetry data also provide important feedback to the designers.



As the number of parameters is large, continuous surveillance of the data is carried out by the mission computer, which can present the data in graphical and tabular forms and also alert the operator in case of any abnormality. Even one bit of data being abnormal will be a nerve-racking experience to the operating crew.

The telecommand system provides the capability for receiving, decoding and distributing commands sent from the control centre. Commands are required for operating payloads, switching on/off heaters, firing thrusters, selecting a redundant system, etc. Here again the command code is a set of bits which are to be transmitted on a RF carrier. INSAT uses a 100 bps data with FSK/FM modulation on a 6 GHz carrier. Unlike telemetry, it is important to guard against even a single bit error in the transmission. For this purpose forward error control coding is used.

Launch phase operations

In today's technologies, satellites are not just thrown in space. They are designed and built on ground but transported to the destination in space. Before reaching the final slot, each satellite, like INSAT, goes through a launch phase wherein many critical activities are undertaken. The launch and early orbit phase is full of excitement and MCF bubbling with activities. In the first one or two weeks, the major operations include firing of big rocket engines for orbit raising, opening out of antennae and solar panels, an elaborate testing of payloads, etc. In INSAT the transfer to the geostationary orbit is carried out by using a liquid apogee motor which gives a thrust of 450 N. This motor has to be fired in three parts for about 100 min in all, resulting in a propellant consumption of about 1000 kg. This must be compared with the propellant requirement for the next ten years of on-orbit operation, which will be around 200 kg. Deployment of the appendages is also critical as any failure will result in a total loss of mission.

So far MCF has supported six launches and in each case the signal from the satellite was received minutes after the satellite was put into orbit by the launch vehicle. This orbit is a highly eccentric one with perigee as close as 200 km from the ground and apogee at the geosynchronous height. Consequently, there is a large motion of the satellite relative to the ground calling for tracking antennae. Also, a given earth station cannot have continuous radio contact in successive orbits. For this purpose, additional tracking stations are deployed and a communication interface established with the tracking network. The launcher agency is also linked by dedicated communication channels so as to monitor

Mission sequence.

carefully the prelaunch operations which go on for 7–8 weeks. Prior to the launch the entire hardware at MCF undergoes revalidation. The mission control software is tested extensively and the operations crew are trained to carry out the sequence of events (SoE) pertaining to the mission. The simulation and rehearsals are conducted in several stages and last a few months.

Normal phase operations

At the end of launch phase operations a satellite and its payloads are tested for their functioning and declared operational from its slot in space. Then onwards, the mission life of the satellite begins and the operations undertaken in this period are called normal phase operations. Spacecraft operations call for considerable planning and critical analysis so as to ensure flawless execution of commands and a fast response in the event of any contingency, pinpointing the problem area in case of a malfunction. Based on the user requirements nominal operations are detailed as an event schedule on a time line. Unforeseen behaviour is taken care of by issuing operations directives generated by the subsystem engineers. Equal importance is given for trend analysis and performance monitoring to detect even minor anomalies at the earliest. Emphasis is also laid on generating periodical reports as well as anomaly reports.

Though the operations may look quite routine for a casual observer during the normal on-orbit phase, the stakes involved are so high that it is important to monitor continuously the state of health of the satellite. A careless command or unwatchful operator can bring the end of life to a mission. The parameters pertaining to attitude control are rather important in this context. The attitude and orbit control system (AOCS) of INSAT in the normal on-orbit phase is designed around the concept of biased angular momentum. By spinning two flywheels an angular momentum of about 130 N m s is maintained, giving gyroscopic stiffness to the body. The disturbance torques are taken care of by adjusting the wheel speeds, making use of the principle of conservation of angular momentum. Unidirectional disturbances may result in the wheel speeds going to extreme values and hence at such times thrusters are fired (typically for 16 ms) to bring the wheel speed within the operating range. Even though the attitude control system works based on a closed-loop onboard control, it is important to monitor the system parameters from ground. Even a small error of 1° in the pointing will result in a shift of antenna beam by about 600 km on the surface of the earth, affecting all the user services. Such misorientations can arise for a variety of reasons like an anomalous thruster firing, a single event upset in the processor code, attitude sensor failure, etc. If any of these were to occur, quick corrective actions are called for. Depending on how high the body rates are, the recovery process may take anywhere from 15 min to 10 h. At such times of loss of attitude lock, the experts assemble at the control centre within 15 min irrespective of the time of occurrence of the anomaly.

MCF facilities

MCF is an integrated control facility with multiple earth stations co-located with mission control centre. It presently has three full-motion antennae with trans-receive capability in C-band (6/4 GHz). There are a number of limited-motion antennae to support payload test in C-band, extended C-band, S-band (2 GHz) and UHF (400 MHz). It also has a boresite facility for zero range calibration and RF testing. The interface between earth stations and satellite control centre (SCC) is at 70 MHz. SCC houses the base-band equipment for telemetry, tracking and command, data processing system, timing systems, recording facilities and communication systems. The computer systems include PDP 11/70s and VAX systems. In keeping with the present-day trend, the future missions will be supported on distributed processing system. Besides the workstations, telemetry is being processed on PCs with suitable add-on cards developed in-house. The mission control software can be broadly divided into two categories – one for real-time data acquisition, processing, health monitoring and trend analysis, and the other for processing the tracking data, determining the orbit, predicting the orbital events and planning correction manœuvres.

A centralized power system provides uninterrupted power supply for each functional area. The captive generating system consists of six generators of 310 kVA capacity each. A variety of air-conditioning systems provide the required environmental control. It is a matter of great pride that all these systems are maintained in-house.

Initially it was a necessity to grow a garden around the facility to avoid collection of dust all around. Over the years the garden has been developed so well that it won a prize in the horticultural competition at the State level.

The facility started with just about 40 persons in the year 1980. Now even the security staff belonging to the CISF exceed this number! The present staff strength of MCF is around 300, drawn from different engineering disciplines, technical branches and administrative areas. At any time 18 persons are on round-the-clock shift duty headed by an Operations Manager. He or she will coordinate with the users on real time as required. The spacecraft controllers undergo a well-structured training programme for six weeks followed by on-the-job training for a similar duration. It is noteworthy that MCF was

asked to organize a course for such controllers working for Arabsat, a multinational organization controlling similar satellites. If MCF has been able to achieve smooth and flawless operations for all these years, it is only due to the personal involvement of everyone of the staff members who takes pride in his or her job with an excellent team spirit.

MCF has been responsible for several innovations such as the survival of INSAT-1B through the eclipse season in spite of the loss of both the onboard batteries, use of attitude control thruster firings for orbit adjustment, detailed on-orbit measurement of antenna footprint, etc. MCF has also taken the lead in indigenization programmes as well as technology transfer to the industry.

Into the future

INSAT system is still in the stage of growth in terms of introduction of newer payloads and newer services. Correspondingly, the augmentation of the facilities at MCF will go on for the next few years. For example, presently, new earth stations are being built for testing Ku-band (11/14 GHz) communication payload and Mobile Satellite Service (MSS) payload. In the next three years a launch of INSAT is planned every year. There will also be experimental missions carried on the test flights of GSLV. Each launch calls for calibrating, checking and revalidating the performance of every subsystem to ensure fail-safe operation. The launch seasons are so hectic that the MCF personnel have very little time for other activities. However, the routine operations tend to be less glamorous, but provide useful feedback to the designers. ISRO is one of the few organizations in which the satellite design and operations are carried out under the same umbrella. This is sure to pay rich dividends in the long term.

Vegetarianism: A nutritional appraisal

K. T. Achaya

Vegetarianism in India is perhaps 3000 years old. What is the extent of flesh consumption at present? How do vegetarian diets stand up to scrutiny in the light of modern nutritional knowledge? What of the future? These are the questions addressed in this paper.

NOWHERE in the world except in India is the concept of vegetarianism really commonplace, or accepted without explanation. Nor is this surprising, since the vegetarian ethos was propounded here by the Vedic Indians as early as about 1000 BC. There are many today who are a product of total vegetarian eating for as long as hundred generations, and survive, reproduce and live full and satisfying lives, both physically and mentally. So it has been done, and can be done. There is room, however, to review the current trends in the use of animal foods, and the practice of vegetarianism, in relation to the knowledge of scientific nutrition that has been unravelled over the last century or so.

Proportions and causes

Census figures of 1971 record the proportions of vegetarians that exist in the various states of India. Among the high-vegetarian-population states (expressed as percentages of the population) are Gujarat 69, Rajasthan 60, Punjab–Haryana 54 and Uttar Pradesh 50. At medium levels come Madhya Pradesh 45, Karnataka 34, Maharashtra 30 and Bihar 24, while the low-vegetarian-population states are Tamil Nadu 21, Andhra Pradesh 16, Assam 15, and Kerala, Orissa and West Bengal 6 each. The overall figure for vegetarianism in the whole country in 1971 was 28%.

What is the nature of this vegetarianism? Reliable dietary data have been collected for the years 1979–81 by the National Nutrition Monitoring Bureau, Hyderabad, in 10 states spread all over India[1]. In the rural areas of these 10 states, the consumption figures for fish and other flesh foods (including eggs)[1] are shown in Table 1. Everywhere, fish intake is much higher than that of meat, the averages for each of these for the 10 states being about 10 g of fish and just 3 g of meat a day. Since vegetarians form about one-quarter of the popula-

K. T. Achaya resides at Flat GB, Wood Creek, 115, 3rd Main Road, Defence Colony, Bangalore 560 038, India.

Table 1. Nonvegetarian food intakes: Rural dwellers (g/consumption unit/day)

Region	Fish	Other flesh foods	Total
North			
Uttar Pradesh	3	2	5
Madhya Pradesh	0	0	0
South			
Kerala	37	1	38
Tamil Nadu	3	8	11

West			
Maharashtra	11	3	14
Gujarat	1	0.5	1.5
Mean, about	10	3	13
Weighted mean for nonvegetarians, about	13	4	17

tion, the daily averages for nonvegetarians as a whole are 13 g of fish and 4 g of meat, a total of 17 g per head per day. In other words, in India, the nonvegetarian item by and large represents just one more vegetable, only a small part of the total food. Larger amounts of fish are eaten in coastal states like Kerala (37 g), and West Bengal, Andhra Pradesh and Orissa (17–12 g)[1]. In Goa and the Andaman Islands, data from other surveys conducted around the same time show that per capita fish consumption is as high as 100 g a day, with practically no meat at all[2].

Two factors are involved in vegetarianism. One is the ethical or religious belief, to which have recently been added economic and environmental concerns. The other is income, because meat and, slightly less so, fish are expensive items of food. Table 2 shows intakes of nonvegetarian foods for various income groups in Kerala, Tamil Nadu and Gujarat[1]. In Kerala, 94% of the population are nonvegetarians: fish eating is widely prevalent, and income is not a very major determinant. In Tamil Nadu, religious belief and the income effect are both depressants of nonvegetarian intake, but the reason seems to vary at different levels. Upper income groups are vegetarians through belief, lower ones through income scarcity. More meat than fish is eaten at all levels, a distinct and somewhat surprising reversal of the general rule for a coastal state. Gujarat too has a long sea coast, but the large populations of Jains and Vaishnavites are responsible for very low consumption of both fish and meat at all income levels[1].

Simply the fact of living in cities seems to influence the nature of food intakes in several respects[3]. The dietary data in Table 3, showing the consumption of nonvegetarian food in Trivandrum, Madras and Ahmedabad, the capitals of the three states that have just been discussed, illustrate in exaggerated form the rural deductions just made[3]. In Trivandrum, high-income groups take both fish and meat, other groups mainly fish. In Madras, again the distinct preference among upper-income groups for meat over fish is apparent even when both can be afforded; is not, fish is consumed. Quantities are low in Madras upper-income groups because of ethical vegetarianism. In Ahmedabad, there is far more nonvegetarian food consumed than the average 1.5 g/day in rural Gujarat (Table 1). Again, meat is preferred over fish, reflecting the choice of the cosmopolitan (and perhaps not always Gujarati) upper-income groups of that city.

Table 2. Nonvegetarian intakes: Rural dwellers (g/consumption unit/day)

Region (population group)	Fish	Other flesh foods	Total
Kerala			
High-income	45	9	54
Middle-income	47	1	48
Low-income	33	0	33
Tamil Nadu			
High-income	3	8	11
Middle-income	4	9	13
Low-income	1	7	8
Gujarat			
High-income	0	0	0

Low-income	17	8	25
Ahmedabad			
High-income	4	19	23
Middle-income	1	5	6
Low-income	2	10	12

The complexions of regional diets

So far we have focused on the nonvegetarian part of Indian diets. Lets us now look at the rest of the diets, shown in Table 4 for the rural areas of four states situated in the north (Uttar Pradesh), south (Tamil Nadu), east (West Bengal) and west (Gujarat) of the country[1]. In all these diets, nonvegetarian items form only a very small part: rural Indian food everywhere in the country

is essentially vegetarian. The quantities of cereals and pulses consumed in all states are fairly similar, though the cereal used will differ, and to a lesser degree the pulse. Uttar Pradesh would have mostly wheat, Tamil Nadu and West Bengal mostly rice, and Gujarat rice, wheat and bajra. Intakes of roots and tubers, and of vegetables, are low in Tamil Nadu and Gujarat, and high in West Bengal. Consumption of milk and its products is low in West Bengal and exceptionally high in Gujarat. The levels of calories, proteins and fats calculated from the above dietary components[1] are shown at the end of the table, but these are better considered a little later, along with the quantities of other minor nutrients derived from these diets.

These nutrient intakes[1] are shown in Table 5, along with the 1989 recommended daily intakes for each nutrient laid down by the Indian Council of Medical Research[4]. In the new norms, the weights of an Indian reference man and woman have been set higher (at 60 and 50 kg, respectively) than the current averages in order that the levels of nutrients recommended become targets to be reached by the better-built citizens of tomorrow. This may make some of the actuals appear more deficient than they really are for the smaller people. Generally speaking, calories, proteins and fats are fairly well met even in average Indian rural diets. Calcium and iron are apparently adequate, though iron represents a special case, which will be discussed later. Vitamin A intakes are really low, and are reasonably satisfactory only in Bengal, thanks to the high consumption of green leafy vegetables, a cheap and excellent source of this vitamin. Other nutrient requirements are more or less met. It would appear that, generally speaking, Indian-style cereal-based diets, though containing very little nonvegetarian foods, are nutritionally fairly satisfactory, and can be made even more so with greater buying power and some dietary knowledge and alteration. Let us now look into our foods and cooking practices in greater detail.

Table 4. Average regional rural diets (g/consumption unit/day)

Indian food practices

Many traditional Indian habits have come down to us from very ancient times, and are based on the food materials actually available, on deductive observations in the past of their effects on health, and on the overall Indian food ethos. These practices have much to

Table 5. Nutrients present in Indian rural diets

[b]Liver and eggs: rich; cereals, green vegetables, banana, orange: moderate.
[c]Mostly from animal foods and bacterial activity (see text).
[d]Visible fat only.

commend them. Everywhere in India cereals and pulses are eaten together: rice with sambhar, chapati with dal, and combination cooked foods like the idli, dosai, dhokla, pesarattu, khichdi and holige. There is an important protein complementation effect involved[4,5]. Cereal proteins carry good levels of the two essential amino acids cystine and methionine, and pulse proteins that of the amino acid lysine. When both are taken together, these amino acids complement each other, raising the total protein eaten to one of higher quality. If percentage marks are given, eggs, meat and fish proteins would score about 80 and milk about 72. A cereal–dal combination would score about 65, though each protein in itself would score only 50–55. Add to this some milk or curd, and there is not much to choose in protein quality between vegetarian and nonvegetarian diets taken as a whole. A second point about Indian-style diets is that they are rich in dietary fibre[5]. This is a recent term which means all complex carbohydrates that are not broken up by the digestive enzymes and are, therefore, not absorbed, thus passing into the stools. Today, many diseases of the lower colon, like cancer and constipation, are being linked with an insufficiency of dietary fibre, and hence of long intervals between evacuations. Indian diets rich in cereals and vegetables do well on this count. So do they in terms of fat[6]. Rice and wheat carry about 2–4% of invisible fat each, and consumption of the usual 500 g of cereal a day would give 10–20 g of fat right away. Indian diets have been computed to contain a total of as much as 25 g of such invisible fat a day on an average[6]. Fermented foods have much to commend them. The digestibility of both carbohydrates and proteins in foods like idli and dhokla is very high, since these entities have been broken down during fermentation[7,8]. Any iron that is present becomes ionized and, therefore, available to the body. Curds carry microflora developed during fermentation, which serve to replenish those in the lower intestine and are helpful in digestion and in warding off infection.

Today the virtues of liquid unsaturated vegetable oils are being publicized in the western countries. India has had a long tradition of the use of such oils in daily cooking. Ghee has had a place of veneration that current nutritional science does not tend to endorse[9].

Raw foods are valued because they are one way of ensuring a good supply of a nutrient like vitamin C, which is quickly destroyed by air, light and heat. Western salads of raw vegetables and fruits are meant for this purpose, and in India we have long cherished our raw chutnies, pacchadis, raitas and kocchumbers made up of ground green ingredients. In fact, cooking without fire was a distinct Vedic category of food preparation[10–12] and included items like pickles of lime and mango with spices and salt, or sugar-preserved items in which nutrients are well conserved for year-round use. Sprouting of mung, chana and ragi is a well-established Indian practice, and often the products are eaten raw, which further conserves vitamins. Vitamin C and several B vitamins are nearly doubled on sprouting and iron is released from bound forms[7,8,13]. An age-old practice thus finds modern nutritional vindication.

Indian historical injunctions regarding hygiene have a thoroughly contemporary connotation. One was obliged to wash hands and the mouth before and after eating, eat from disposable plates to avoid cross-infection, and not to sip water from a glass but pour it in. Leftover food was not to be eaten, which in pre-refrigerator days made sound sense. There were two kinds of foods in the Aryan ethos[12]. *Kaccha* foods were everyday foods, eaten daily, like rice and dal; these boiled foods were to be cooked and eaten only within the kitchen by the family members. *Pucca* foods could be taken outside, and also shared; these were usually fried foods, which, as we know today, have a much longer keeping quality, and are not prone to infection. Sociological theorizing was in this instance a basis for sound nutritional practice.

Animal foods in nutrient terms

Proteins of high quality were once considered the major virtue of animal foods. There is truth in this in terms of amino acid quality, but as we have seen, blending of proteins from cereals and pulses compensates fairy adequately. The quantity of protein in fresh meat and fish is 18%, whereas most dals carry between 20 and 23%. However, because of swelling and bulkiness, it is easier to consume say 100 g of meat than to eat the same weight of dal, and the gas-forming nature of most dals is also a drawback[8,13].

There is a bit of a mystery about iron. It has repeatedly been shown that from nonvegetarian diets, there is high absorption of any iron present in the food, whereas the same quantity of iron from a cereal-based diet is absorbed only to the extent[14] of about 3%. Also, from the same diet, a pregnant woman will absorb about 5% of the iron and a woman suckling a child[4] 7%. Some sort of feedback mechanism operates, and vegetarian diets do face a problem of low absorption. As a result, most Indians are slightly anaemic by western standards, and consumption of iron-fortified salt is being recommended even on a national basis. Studies in large groups have shown excellent and sustained improvement in blood iron levels after taking such salt[15].

Vitamin B_{12} is an 'animal' vitamin, present in high amounts in liver and to lesser extents in meat. From purely vegetarian diets it is difficult to get enough of this vitamin to meat normal needs, and yet there is little evidence of deficiency in India by way of pernicious anaemia[7]. This has been attributed to several causes:

the higher absorption (70%) of the vitamin from food by vegetarians than by meat-eaters (16%), the presence of bacteria (which synthesize vitamin B_{12}) on the surfaces of green vegetables and in water supplies carrying decaying vegetable matter, and the poor hygienic practices prevalent in India[4]. The quantity of the vitamin needed daily is very small, only one mcg a day. Yet many vegetarians from India who migrate to England frequently develop signs of vitamin B_{12} deficiency like pernicious anaemia; the type of bacteria populating their small intestines has been found to change, and the number of bacteria drops considerably, probably reducing B_{12} synthesis in the small intestine markedly[16]. Also, a large number of antagonistic factors may come into play, like the use of more processed foods, an excess of vitamin C and copper, and excessive medication. Cholesterol is another product of animal metabolism, found in eggs and meat, and also in milk, butter and ghee. Consumption of these is low in India, but the high incidence of cardiovascular disease among Indians living in England, once tentatively attributed to oxidized cholesterol found in heated ghee freely used by Indians there, is now being linked[9,17] to the *trans* fatty acids present in ghee to the extent of about 4%. Fears regarding cholesterol consumption have sharply depressed intakes of butter (which is also a saturated fat) in advanced countries, perhaps without justification. Cholesterol in milk itself is at a low level and milk is not considered a major source.

Global concerns

In India, in the recent years there has certainly been a trend towards a higher degree of nonvegetarianism among traditionally vegetarian families. Many factors are operative. Better purchasing power among the middle class is one of them, and the aping of the habits of the so-called upper class, the executive and the film star. To restless younger people, it represents part of a desire to break traditional shackles, especially when they travel abroad alone and undergo the travails of finding appetizing vegetarian food when on the move. Whatever it be, the phenomenal growth during the last two decades of the egg and chicken industry in India is a reflection of the spread of nonvegetarian eating habits among Indians.

The west, on the other hand, seems to be moving steadily towards vegetarianism. Both in Britain and the USA, some 7–10% of people, especially the younger generation, are believed to have become vegetarians. Many reasons are given for this. One is the humanitarian concern of *ahimsa*. A more important reason is the realization that the animal is an inefficient converter of feed materials into meat or milk. The same food grains which an animal is given could feed several human beings, and the production of a typical western non-vegetarian diet of say 3000 calories has actually used up many times that value in terms of feed calories. There is a growing realization of the fact that our earth is a single, finite spaceship in which the whole of humanity will sink or swim together: food must be found for everyone, and animal food is too energy-expensive to meet the need.

What of the future? One can only hazard a guess that a new genetic revolution in food plants is on its way, which may increase grain yields to an extent that can hardly be visualized. If grain production from the same agricultural land area goes up dramatically, and if the population of the world gets stabilized, the economic argument will lose strength. Whether the ethical or moral one will continue to prevail remains an open question.

Cursive English script recognition – A knowledge-based system

P. V. S. Rao and T. M. Ajitha

Script recognition by computers becomes extremely difficult due to variability at the input arising from a variety of reasons. Most existing recognizers are based on statistical pattern recognition techniques and require extensive training. This system uses domain knowledge to extract the broad shape features while filtering out the deformations and other variations in shape as 'noise'. This eliminates the need for any type of training. The performance of the system (even in a writer-independent task) is in the range of 95–100%, which compares very favourably with the current state of the art. This approach can be used for Indian language scripts too.

SCRIPT recognition – recognition of handwritten words and characters by computers – is receiving a lot of attention nowadays due to its practical applications in many areas: office automation, bank cheque processing, postal address and ZIP code recognition, signature verification, and, in general, document and text recognition. It is, in addition, a challenging area of research.

Script recognition can be accomplished using either of the following two approaches: recognizing words as integral units or visualizing each word as being composed of discrete characters. This distinction between word- and character-based recognition systems is particularly significant for cursive English script, where each word is not merely a string of discrete characters but a more or less continuous curve where character shapes may get modified to some extent. Recognition of words in terms of individual characters becomes difficult because decomposing a word into character length segments is a nontrivial problem. Segmentation into characters is not needed for a word level recognition system; on the other hand, the number of classes (each word will be a distinct class) increases very substantially in this case.

The different methodologies used for script recognition (character- or word-based) include:

- Point-by-point global comparison (comparison of all pixels in the image).
- Global transformations involving Fourier transformations, moment calculations and rotation according to the principal axis of inertia.
- Extraction of local properties such as lines, end points, T-junctions, corners and strokes.
- Analysis in terms of curvature which involves curve following, detection of concavities and geometrical analysis.
- Structural methods (decomposition of each character into its constituent elements, topological description and reduction of each character into a graph).

P. V. S. Rao and T. M. Ajitha are in the Computer Systems & Communications Group, Tata Institute of Fundamental Research, Homi Bhabha Road, Colaba, Bombay 400 005, India.

Overview

How can a computer-based recognition system 'learn', i.e. acquire knowledge about the characters and script of a language? How does it organize and utilize this acquired knowledge for actual recognition? The task of handwritten character and word recognition gets complicated due to variability arising from context effects, sloppy writing, subject-to-subject differences in writing style, etc. In fact, even the same person writes quite differently at different times. It is for such reasons that even the best trained optical readers – the human eyes – make some 4% mistakes when reading handwritten script in the absence of context information. According to Mantas[1]: 'Handwritten character recognition is not a simple task as it may appear. Errors in reading hand prints are caused by the infinite variations of shape resulting from the writing habit, mood, style, education, region of origin, health, social environment and other conditions of the writer, as well as other factors such as writing instrument, writing surface, scanning methods and finally, of course, the machine's character recognition algorithms.' The complexity of the task increases progressively as we go from fixed-font recognition of printed text (recognition of specific fonts) to recognition of single unconnected handwritten characters and finally to connected cursive (handwritten) scripts.

The underlying presupposition behind all recognition approaches is that there exist certain invariant properties which define each pattern in the task domain in a unique way and that these properties (parameters) can be determined in a quantitative sense.

In a general case of pattern recognition, each sample or pattern can be represented as a point in an n-dimen-

sional parametric space where each dimension corresponds to one parameter (Figure 1). The set of parameters required for representing the individual patterns at the input would naturally depend on the complexity of the problem domain. Ideally, various instances of each class map into points which cluster into a compact neighbourhood in this space. Also, there would be no significant overlaps between regions defining the classes. Both these are necessary conditions for pattern recognition systems to perform well. These facilitate deriving a 'mean' representation for each input class, determined by the input instances (belonging to this class) encountered at the time of training.

For instance, in the case of the minimum-distance approach, the 'distance' between an input pattern and the 'mean' or 'class prototype' is a measure of the dissimilarity between them. The input pattern will be recognized as the class prototype 'nearest' to it. In the maximum-likelihood approach, the likelihood that a test sample may be a member of a cluster or class is determined on the basis of probabilistic distributions in the parametric space. The input pattern is put into the class with the maximum value for the probability of occurrence.

Many existing recognition systems use statistical pattern recognition techniques based on minimum distance, maximum likelihood, hidden Markov models[2], neural network models[3,4], etc. They are trained 'by exposure' to representative samples; the system tries to extract representative models for each of the script characters (or words) as encountered in real life. Understandably, these models would be distorted versions of the corresponding ideal character shapes.

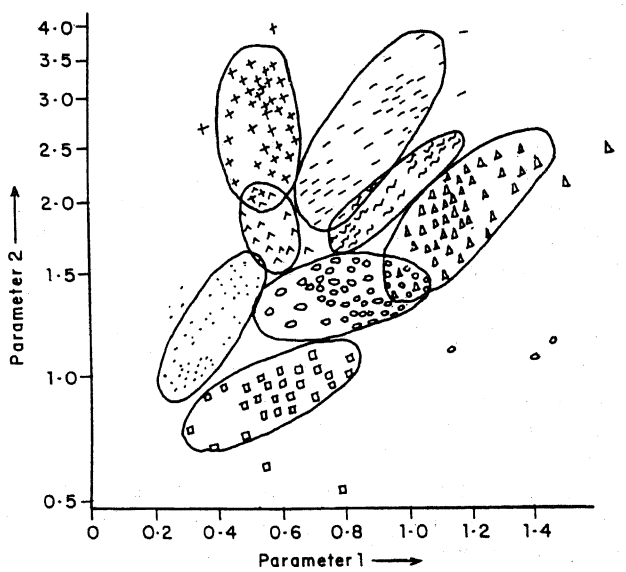

Figure 1. Clustering in parametric space.

Figure 2 shows some representative patterns 'learnt' by a neural network classifier proposed by Schomaker[4], for the characters */a/*, */b/*, */g/*, */k/*, */n/*, */o/*, */p/*, */r/*, */w/*, */x/*, */y/*, */z/*. It can be seen that the mean representation or class prototype is rather distorted and is quite different from the 'ideal shape' for each particular class (character). This is because while developing a 'statistical model' for the respective input classes, the classifier is, in fact, modelling not only the canonical shape behind it but also the variations (or 'noise') encountered at the input level.

In contrast to the statistical approaches mentioned above, our feature-based approach[5,6] is based on the fact that for each script character or word, there exists notionally an ideal pattern – the copy book version – which the writer is attempting to reproduce while writing. The variations or distortions that occur are viewed as added noise. Essentially, our system represents each individual character/word (input class) by the corresponding canonical shape (prototype). The task of the recognition system is thus to map a noisy real-life input (Figure 3 *a*) into the copy book counterpart (Figure 3 *e*). This is done in two steps.

Step 1: Filter out (local) shape-related distortions and retain only the broad (global) shape features of the input shapes by choosing an appropriate set of parameters which preserve only the very essential information regarding the shapes (Figure 3 *b*). It can be easily verified that there exists only one way of linking the feature points while preserving the order. The shape distortions in Figure 3 *a* have been eliminated in the reconstructed pattern (Figure 3 *c*).

Step 2: Filter out the distortions relating to size, shape and slant. Figure 3 *e* is such a reconstruction. (This is accomplished by quantization of parameter values as shown in Figure 3 *d* and is discussed in greater detail later.)

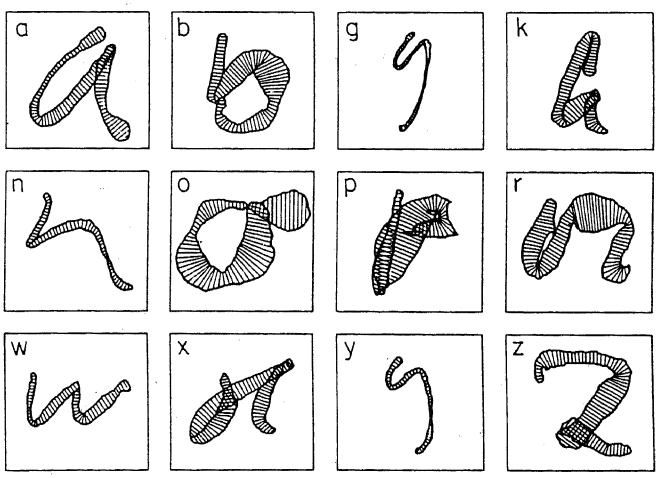

Figure 2. Abstract shapes derived by Kohonen net trained on samples written by a single subject (taken from ref. 4).

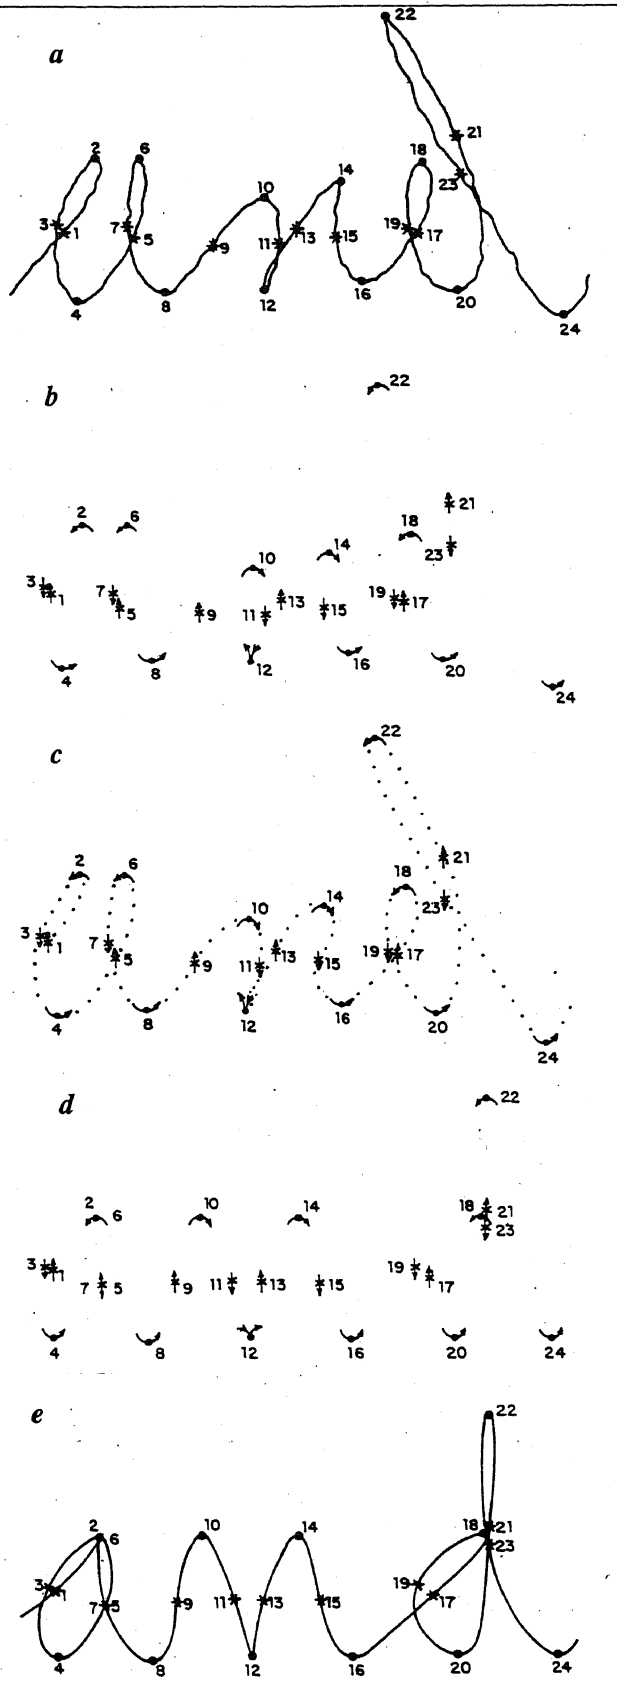

Figure 3. Feature extraction and reconstruction after normalization. *a*, Original pattern. *b*, Information captured by the feature set used. *c*, Reconstruction based on information in (*b*). *d*, Feature set after quantization. *e*, Reconstruction using quantized feature set.

Thus, this feature-based approach helps us to filter out the deformations, thereby ignoring the actual and detailed shapes of the character and to retain only broad shape features. Consequently, there is no need for analysing different samples corresponding to each individual character since each of them carries the same broad shape features. This makes training superfluous in this approach.

Selection of parameters

As mentioned earlier, recognition needs to be performed on the basis of the attributes of the patterns involved; these are represented as values of specific physical parameters of the signal. Selection of an appropriate minimum set of parameters is thus an important step for any script recognition system, and, in general, for all pattern recognition systems. For example, the selected set of parameters should not be sensitive to the style (and mood) of the writer (or to any of the other variations that occur in practice). It would be ideal if these parameter values remain invariant irrespective of contextual effects, variation in size, and placement of individual characters within a word. A character level recognition system should also be insensitive to all possible variations of individual character shapes when they are concatenated to form a word. This is a very important requirement for cursive script recognition in English.

In the current feature-based approach, the parameters selected permit the retention of broad shapes by capturing the archetypal characteristics of each individual character, and filtering out as noise all writer-specific, context-dependent and other distortions such as those relating to shape, size and slant. We accomplish this by heavy quantization of the parameter values (Figure 3).

Feature-based recognition system

In our parametric model, we use features concerned with points of minimum radius of curvature (minima) and maximum radius of curvature (maxima) – the feature points – for representing the characters. The feature vector representing an individual character consists of the points of minimum radius of curvature – the minima – of the character. The attributes we use are the location of the minima and the direction of curvature at these points.

Figure 4 shows the word */andy/* and the minima and maxima points; the minima bear even numbers and the maxima are the points with odd numbers.

The attributes of the minima and maxima are insensitive to local fluctuations in the shapes of the actual curves. A recognizer using these attributes would, there-

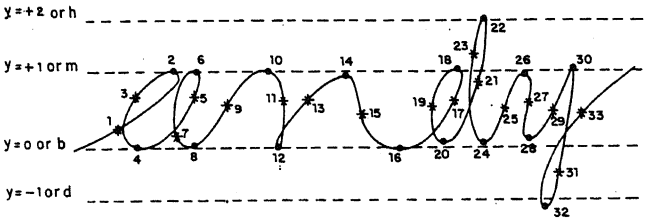

Figure 4. Feature points for the word */andy/*.

fore, be reasonably robust. It is, in principle, possible to train a statistical recognizer to recognize script words using this information alone. Though insensitive to shape fluctuations, such a recognizer would still be sensitive to the fluctuations in slant, size and position. Such a recognizer would, therefore, need a large number of training samples. To obviate this, it would be desirable to 'standardize' the character size which manifests itself as horizontal and vertical distances between successive minima. This standardization can be conveniently done by warping the characters to fit into a uniform grid, i.e. by quantizing the X and Y coordinates of the minima points. This takes care of variation in character sizes. This has, in fact, been done in Figure 3 *d*. Similarly, quantizing the slopes of the maxima would eliminate the fluctuations in slant angle while writing.

Each minimum on the curve is characterized by position (X and Y coordinates) and curvature. The curvature is quantized to three values to carry the direction information: 'a' for anticlockwise, 'c' for clockwise and 's' for sharp turns (where the curvature could be either clockwise or anticlockwise). The Y coordinate value is quantized to four possible values: 'b' and 'm' (baseline and midline) for characters such as */c/* and */n/*; 'h' and 'l' (highline and lowline) for characters with ascenders and descenders such as */h/* and */g/*. X coordinate values are expressed as relative displacements as follows:

- for minima at the baseline and midline, with respect to the nearest left minimum at the same level.
- for minima at the highline and lowline, with respect to nearest left minimum at any level (because it is unlikely that there will be an adjacent left minima at the same level in these cases).

This helps us to distinguish between */d/* and the combinations such as */el/* or */il/*. Figure 4 and Table 1 illustrate this scheme. Minima 2, 6 and 18 have the value 'a' (anticlockwise) for direction while minima 10, 14, 26 and 31 have the value 'c' (clockwise) for direction. Minima 12 and 30 have the value 's' (sharp) for direction. Minimum 12 has been traced in clockwise direction (as a loop). It could alternatively have been traced as a sharp turn as in the case of minimum 30. This would have made the curvature of minimum 12 anticlockwise; hence, the need for classifying it as

Table 1. Feature vectors for */a/* and */n/* in */andy/*

		character a					character n				
Max.	Serial No.	1	3	5	7	9	9	11	13	15	17
	Slope	U	D	U	D	U	U	D	U	D	U
Min.	X	f	f	n	f		f	f	f	f	
	Y	m	b	m	b		m	m	b	b	
	Curvature	a	a	a	a		c	s	c	c	
	Serial No.	2	4	6	8		10	12	14	16	

'sharp' rather than as clockwise or anticlockwise. X has the value 'n' for minimum 6 because it is very near to minimum 2 at the same Y level and at its left, and 'f' for minimum 10 since it is far from its left neighbour. The X value helps to distinguish between */a/* and */u/*, */g/* and */y/*, */o/* and */v/*, etc. The X coordinates are expressed not as absolute values but relative to each other, so that they remain unchanged even after concatenation of individual characters.

Maxima points on the curve are labelled by the slope angle quantized to the following values: up, down, right and left. The actual thresholds used for quantization are:

$0 \pm 20°$: right (R)
$180 \pm 20°$: left (L)
$90 \pm 70°$: up (U)
$270 \pm 70°$: down (D)

All the above parameters are extracted from single samples of individual letters. The sequence of values constitute the feature vector for the character.

The feature matrix for a word is obtained by concatenating the feature vectors for individual characters forming the word in the same sequence.

A lexicon consisting of feature matrices for all the words in the vocabulary is compiled from the feature vectors of individual characters. The test word written by the subject (which is to be recognized) is similarly analysed to yield the corresponding feature matrix. This is then compared with the feature matrices of all words in the lexicon. Recognition is accomplished on a best match basis, i.e. either the exact match or, failing this, the nearest match.

Details of implementation

Data acquisition and preprocessing

Both reference and test data are collected using a graphics tablet connected to the serial port of an IBM-PC-compatible system and feature vectors are extracted

therefrom. Specimen samples for the 26 English lowercase letters are collected from a single subject. Feature vectors extracted from these letters constitute the reference data for the recognition system. The writer has to write the input pattern on the graphics tablet using the digitizer pen. The tablet digitizes the handwritten pattern and sends a stream of X and Y coordinates to the host computer through the serial port. These data are stored in the ASCII file format. To facilitate extraction of height information, it is necessary to ensure that the script is in a straight line and that the characters are of a reasonably standard size. To this end, the upper and lower reference lines are provided on the writing surface as in ruled copy books for children. The subject is required merely to write broadly within these lines. There is no need for anything like copy book precision.

Radius of curvature extrema – the feature points on the curve – can be located using one of several alternative methods. One of the easiest ways to locate minima (and maxima) is by using the fact that the stylus travels fast and almost in a straight line near the maxima but is slow and almost doubles back on itself as the curve turns nearly 180° around minima. The chord distance (not arc distance) between two sample points separated by constant time would, therefore, be minimum around minima and maximum in the neighbourhood of maxima. The relevant parameter values can be extracted for each minima and maxima and quantized easily.

Handwritten characters are usually not vertical in their orientation; they tilt to a greater or lesser extent, usually to the right. The tilt or slant remains more or less invariant for each person and is one of the features that characterize an individual's handwriting. It would seem very desirable to eliminate this slant so that we can deal with more standard – essentially vertical – characters. This can be done by means of a number of slant estimation and correction processes. It turns out that, except for extreme slants, this is not really essential, since our method of parameter representation and quantization for script characters is robust enough to tolerate even major slants in the writing.

Comparison and recognition

For recognizing the given input word, we narrow down the list of prospective candidates (dictionary words or reference patterns) on the basis of a rough match and perform a detailed matching only within this short list. The number of minima in a word is used as the criterion for this short-listing. All dictionary words where the mismatch in the number of minima exceeds 3 are rejected. If an exact match is found within the short list, recognition is successful. Failing this, the best match is identified from the short-listed set of words. We use a comparison procedure based on dynamic programming which permits efficient matching of feature vectors even in the presence of spurious minima and absence of genuine minima in the test pattern. The input word is recognized as the word in the short list which matches the test pattern best. Recognition fails if either the short list is empty or if, for all words in the short list, the mismatch during detailed matching turns out to be excessive.

Experimental results

As stated before, each character is represented by a feature vector, a sequence of labelled minima and maxima points. Each minimum is characterized by (a) location (quantized) and (b) direction of movement (clockwise, anticlockwise or sharp turn) while each maxima is labelled with the direction of movement. Recognition is successful if an exact match is found within the short list. Failing this, the best match is selected as the candidate.

Data sets were collected from 10 (male and female) subjects from different age groups and educational backgrounds. Each subject was asked to write the 63 words of the vocabulary (word length varied between 3 and 7 characters) twice on the graphics tablet. The vocabulary included words such as 'fill' and 'fell' which are very smilar to each other. The reference character set (26 lowercase alphabets) was taken from a different subject. Standard lexical entries for each word in the vocabulary were generated from these by appropriately concatenating the feature vectors of these individual letters. Recognition results (using this 'common' set of lexical entries as standard and the word sets written by each subject at the test set) are summarized in Table 2.

Each subject was also asked to write ten sets of the word */and/*. These were pooled together and used in a separate recognition experiment. In this case the overall recognition score was 93%. Figure 5 includes some of the samples which were recognized correctly despite the significant shape deviations in many of them. This demonstrates the robustness of the approach followed.

Table 2. System performance

	Recognition scores (%)	
Subjects	Word set 1	Word set 2
Subject 1	95	97
Subject 2	97	97
Subject 3	98	98
Subject 4	97	97
Subject 5	97	98

Subject 7	100	100
Subject 8	100	97
Subject 9	100	100
Subject 10	100	100

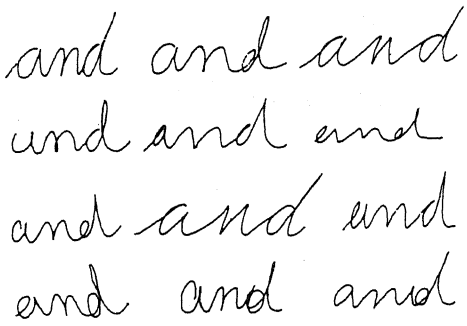

Figure 5. Samples of the word */and/*.

Discussion and conclusions

In this feature-based approach for script recognition, we introduce an appropriate empirical parametric model for cursive English script. The minimal set of parameters used permit the retention of the shapes of the script characters, while ignoring the context-dependent, writer-specific and other distortions in shape, size and slant of characters. Resynthesis based on extracted parameters was successful in recreating the shapes of connected words and individual characters. This demonstrates the validity of our approach.

This is a knowledge-based system; knowledge about the task domain is contained implicitly in the set of parameters chosen for representation and the manner in which they are processed. Needless to say, any recognition system needs knowledge regarding the task domain at some stage before it can start 'recognizing' the input. Statistical systems start without any *a priori* knowledge. Consequently, such classifiers acquire this knowledge through elaborate training. In the case of hidden Markov models and neural networks, the topology chosen implicitly incorporates some knowledge about the task domain into the system. This, however, is not enough to dispense with the need for training. In the current feature-based approach, we use knowledge about the task domain to choose an appropriate parametric model which extracts and retains only the canonical or prototype shape information for specimen words in the lexicon on the one hand and for the test words on the other hand; in both cases, the model filters out real-life shape deformations as 'noise'. This obviates the need for training of the type needed for statistical or neural-network-based approaches. Only an 'initialization' with one sample for each of the 26 lowercase script characters is required prior to recognition. The performance of the system does not degrade significantly even when the initialization and test samples are written by different subjects. The recognition scores are in the range of 95–100%. This demonstrates the robustness of the approach.

The present system is able to handle vocabulary sizes of the order of a few hundreds of words. Though the parameter set selected here is ideally suited for the Roman script, the underlying principle is general enough to adopt for script recognition in other languages, say Indian languages. The set of features or parameters used for representation might, of course, vary across languages. We are developing feature-based recognition systems for some Indian languages and preliminary results are encouraging. Machine recognition of Indian language scripts becomes a particularly attractive avenue for research due to the complexity of the task of adapting Indian scripts to the qwerty keyboard.

REVIEW ARTICLE

Wave–particle duality and Bohr's complementarity principle in quantum mechanics

D. Sen*, A. N. Basu and S. Sengupta

Department of Physics, Jadavpur University, Jadavpur, Calcutta 700 032, India
*Present address: Barasat Govt. College, Barasat, West Bengal, India

Interest in Bohr's complementarity principle has recently been revived particularly because of several thought experiments and some actually performed experiments to test the validity of mutual exclusiveness of wave and particle properties. A critical review of the situation is undertaken and it is pointed out that the problem with mutual exclusiveness arises because of some vagueness in the conventional formulation. An attempt is made to remove this vagueness by connecting the origin of mutual exclusiveness to some principles of quantum mechanics. Accordingly, it becomes obvious that to contradict complementarity principle without contradicting quantum mechanics would be impossible. Some of the recent experiments are critically analysed.

IN classical physics energy is transported either by particles or by waves, and particle and wave are the sole ultimate categories of physical entities. Particles are described by Newton's equation of motion and a wave by a space–time field function which satisfies a differential equation – the so-called wave equation (or field equation), and there is no mix-up. But the classical 'particle' is described in quantum mechanics (QM) by a field function (ψ) satisfying Schrödinger's equation which has a wave-equation-like flavour. Similarly, classical 'waves' are described by quantum field equations in QM which may be recast in a Schrödinger equation[1] for the wave function of the field quanta. The basic difference in the mathematical description of the two distinct classical entities disappears and we are in for the typical wave–particle duality in the world of quantum mechanics.

The wave–particle duality according to Feynman[2] 'contains the only mystery of the theory', while Bohm[3] considered it as one of the crucial 'new features of primary significance' introduced by the quantum theory. Eddington has coined the name 'wavicle' for microparticles and the term 'wave function' has been chosen to emphasize the wave–particle duality, considered generally so fundamental in quantum mechanics. Wave–particle duality is pointed out even in a quark model based on finite-dimensional quantum mechanics[4]. On the other hand, Popper[5] writes '... I nevertheless believe that the quantum theory is in a very definite sense a particle theory (here I disagree with Schrödinger) and in a sense which excludes a duality, analogy or complementarity between particles and waves'.

Notwithstanding such comments, the notion of duality in the physical description which grew in the years following Einstein's work in 1905 continues to spur fresh debate in the wake of some recent experiments on matter–wave interferometry and quantum optics.

Almost 20 years after the seminal work of Einstein, de Broglie extended the wave–particle dualism to material particle in 1924 and signalled the formulation of wave mechanics. Acknowledging the significance of the work, Einstein[6] immediately wrote back that 'de Broglie has lifted a corner of the great veil'. However, in the following years multiplicity of dualist interpretation led Bohr[7] to 'harmonize the different views, apparently so divergent' and to offer a general description of 'atomic phenomena' in the framework of the complementarity principle.

The recent glut of critical comments regarding the validity of Bohr's complementarity principle (BCP) or, more precisely, the conceptual content of the wave–particle duality in the light of new experiments, however, makes it clear that much of the controversy arises because of the prolixity of the formulation, which contains some amount of vagueness (see Box 1). In January 1949 Einstein[8] complained that 'despite much effort which I have expended on it, I have been unable to achieve the *sharp formulation* of Bohr's principle of complementarity' (italics ours). In our view two major shortcomings of the conventional formulation of BCP are: (1) There is no guideline to decide whether a suggested pair of variables/properties should be considered complementary. (2) No precise quantum-mechanical principle is adduced from which the incompatibility can be derived.

When Bohr remarked '... any given application of classical concepts precludes the simultaneous use of other classical concepts which in a different connection are equally necessary for the elucidation of the phenomena'[9], he kept one important question unanswered. If an experiment is performed to measure some properties and use classical concepts for the elucidation of the

phenomenon, how do we ascertain which concepts are to be used and which to be precluded? This difficulty arises mainly because Bohr formulated the complementarity principle without addressing the principles of QM. We can find a parallel in the principle of uncertainty. Heisenberg formulated it without using QM. But later it was demonstrated that the uncertainty principle is implicit in the formalism of QM. Some physicists seem to accept BCP as independent of QM, and its relation to QM remains illdefined. Any attempt to show that mutual exclusiveness (ME) in BCP can be violated without violating QM presumes the view that BCP is independent of QM. It is surprising that no serious attempt so far has been made to see if BCP can be formulated in a way so that it becomes completely consistent with the principles of QM.

In a recent communication[10] we made such an attempt and pointed out that both the uncertainty and the complementarity principles are implied within the formalism of QM. Also it must be clearly understood that they add nothing to the formalism. Instead, they bring out explicitly certain features of QM not quite obvious from the formalism itself. In addition, they focus our attention on some sharply contrasting situations in classical and quantum mechanics and thereby help us realize their fundamental differences. According to Scully *et al.*[11], 'complementarity distinguishes the world of quantum phenomena from the realm of classical physics'.

In the quantum-mechanical description of a physical entity which is classically described either as a particle or a wave, we find that pairs of variables/properties exist which are mutually exclusive in the sense that a *sharp simultaneous knowledge of both is impossible.* Actually these are termed as complementary pairs.

In the above statement we have made ME a *defining property* of complementary pairs. On going through the writings of Bohr on BCP, it is evidently clear that ME is intended to be the essence of complementarity and we conclude that if for a system mutually exclusive variables do not exist, the system is a purely classical

Box 1.

N. Bohr on complementarity principle

'An adequate tool for a complementary way of description is offered by the quantum-mechanical formalism... It must be remembered that even in the indeterminacy relation we are dealing with an implication of the formalism which defies unambiguous expression in words suited to describe classical physical pictures. Thus, a sentence like "we cannot know both the position and the momentum of an atomic object" raises at once questions as to the physical reality of two such attributes of the object which can be answered only by referring to the conditions for the unambiguous use of space–time concepts on the one hand and the dynamic conservation laws on the other hand. While the combination of these concepts into a single picture of a causal chain of events is the essence of classical mechanics, room for regularities beyond the grasp of such a description is just afforded by the circumstances that the study of the complementary phenomena demands mutually exclusive experimental arrangements.' – Bohr, N., in *Atomic Physics and Human Knowledge*, Science Editions, New York, 1961, p. 41.

Box 2.

Pros and cons

1. '... the development of modern physics has enriched our thinking by a new principle of fundamental importance, the idea of complementarity.' – Born, M., *Physics in my Generation*, Springer, New York, 1969, p. 171.
2. 'Complementarity denotes the logical relation, of quite a new type, between concepts which are mutually exclusive, and which, therefore, cannot be considered at the same time – that would lead to logical mistakes – but which nevertheless must both be used in order to give a complete description of the situation.' – Rosenfeld, N., *Nature*, 1961, **190**, 384–388.
3. 'I have, for a long time, adopted the idea of complementarity in the realm of quantum physics, whilst at the same time realizing that it was inadequate. In recent years, I have been led to regard the concept of complementarity with increasing suspicion.' – de Broglie, L., in *The Current Interpretation of Wave Mechanics*, Elsevier, Amsterdam, 1964, p. 7.
4. 'This illogical conflation of concepts was the great quantum muddle which led to the emergence of the notorious wave–particle duality and hence the complementarity interpretation.' – K. R. Popper's view on the Copenhagen interpretation as presented by Jammaer, M., in *The Philosophy of Quantum Mechanics*, Wiley, New York, 1974, p. 448.

one. In every complementary pair he has discussed, Bohr stressed the ME aspect. But a gap was created when he said that wave properties are complementary to particle properties – it is absolutely necessary to know in a given experimental set-up which particle properties are to be regarded as complementary to which wave properties. Classical waves and particles have many common properties. As Bacry[12] puts it, '. . . , there are situations where the two aspects compete to interpret a phenomenon'. But in this respect Bohr's specific statement is significant: 'It is evident, however, that any concrete wave picture is as unable to account for basic experience regarding the individuality of the electron as a corpuscular picture for the superposition properties of radiation fields'[13]. This statement very clearly indicates that the complementarity Bohr meant was between properties of superposed and unsuperposed states and, as we shall see presently, these properties definitely satisfy ME.

In ref. 10 we made a precise statement of BCP in the spirit of the statements made by Bohr and in this paper we intend to examine critically in the light of this precise statement the thought experiments or the actual experiments which claim to violate the Bohrian notion of ME.

That complementary pairs of variables exist for quantum physical entities, no one doubts, and when we measure the precise position of an electron, we know that the concept of momentum has to be excluded. This knowledge comes from the principles of QM. Similarly, if we are doing an interference experiment, say double slit it is the which-state information that is complementary to the appearance of the interference pattern. We want to apply the same criterion in the so-called wave–particle complementarity, identifying the quantum principle responsible for ME in this case.

We can distinguish between two classes of complementarity on the basis of the origin of mutual exclusiveness. These are:

Class I: Pair of variables obtained from a Fourier transform of the state vector and any pair of dynamical variables for which the corresponding operators satisfy a noncommutation relation. These include pairs of canonically conjugate variables.

In this class we have the complementary pairs $\mathbf{r}, \mathbf{p}$ and t, $\mathcal{E}$ derived from $\Psi(r, t)$ and its Fourier transform $\Phi(p, \mathcal{E})$. Also, all pairs of noncommuting variables such as components of angular momentum $J_x, J_y; J_x, J_z$, etc., belong to this class. Similarly, the radiation field variables $\boldsymbol{E}$ and $\boldsymbol{H}$, which satisfy field commutation relation, may serve as the complementary pair in the case of a light beam. Existence of more esoteric complementary pair of variables has also been reported from experiments on elementary particles[14]. ME follows quite clearly from the general quantum-mechanical uncertainty principles for this class of complementary pairs[15].

Class II: A property which depends on interference terms arising from the superposition of a number of states and the property associated with the which-state information form a pair of complementary properties.

In the simplest example of the widely discussed double-slit experiment, one may observe class II type of complementarity by measurement of a single variable. Let the state of a beam of electrons of a definite momentum be given by $\exp(ipz/\hbar)$, the momentum p being along the z direction. At $z = z_1$, a screen is placed with two slits whose centres are at $y = \pm a$ (we take y along the vertical direction). On the right-hand side of the screen the state vector is modified to $\psi = \psi_1 + \psi_2$, where ψ_1 is the wave vector originating from the upper slit and ψ_2 that from the lower slit. If we place a screen in this region at $z = z_2$, we shall observe the interference

Box 3.

Precise statement of BCP and wave–particle duality according to formal quantum mechanics

Existence of complementary pair of variables/properties distinguishes the world of quantum phenomena from the realm of classical physics. Mutual exclusiveness is the *defining property* of complementary pairs.

On the basis of the origin of mutual exclusiveness we can distinguish between two classes of complementary properties. These are:

Class I: Pair of variables obtained from a Fourier transform of the state vector and any pair of dynamical variables for which the corresponding operators satisfy a noncommutation relation. These include pairs of canonically conjugate variables. For this class of complementary pairs, ME follows quite clearly from the general quantum-mechanical indeterminacy principles.

Class II: A property which depends on interference terms arising from the superposition of a number of states and the property associated with the which-state information form a pair of complementary properties. Superposition of states is interpreted with respect to the properties which are measured to show the interference effect and give the which-state information. *This should be considered as the precise expression for the wave–particle complementarity.* The collapse hypothesis of QM ensures mutual exclusiveness in this type of complementarity.

effect. For simplicity we consider ψ_1, ψ_2 as functions of y and z alone. Thus, the probability density function for y as seen on the screen at z_2 is

$$\rho(y, z_2) = |\psi_1(y, z_2)|^2 + |\psi_2(y, z_2)|^2 + \psi_1^*(y, z_2)\,\psi_2(y, z_2) + \psi_2^*(y, z_2)\,\psi_1(y, z_2)$$

The last two terms here give the interference effect. If at $z = z_1$ we make a measurement of y, the result will give us the which-state information and the state vector will collapse to either ψ_1 or ψ_2 and the interference effect in $\rho(y, z_2)$ will disappear. Another interesting feature here is that ψ_1 or ψ_2 need not be eigenfunctions of y; only the respective dispersion in y has to be small.

Experiments based on matter–wave interferometry[2,11,16] belong to this type. A straight edge or a single-slit diffraction experiment may also be included as examples manifesting this type of complementarity. But they seem to have never been discussed in connection with complementarity. The difficulty lies in the fact that the initial state vectors in this case are superposition of a continuous infinity of position eigenfunctions. For example, in the straight-edge case, if we put a series of detectors in the open part near the edge and consider those spots on the screen produced only when the detectors click, the totality of all these spots gives no interference effect. To obliterate the entire pattern, we have to put detectors over a large region near the edge.

Both the interference terms and the which-state information are also obtained from measurement of some suitable pair of variables. Suppose the relevant observables for demonstrating the interference effect is $\hat{\alpha}$ and $\hat{\beta}$. To produce interference effect, the state vector in question must be a superposition of at least two eigenvectors belonging to two distinct eigenvalues of $\hat{\alpha}$ (say). Let us, therefore, take the state vector as $\psi = a_1 |\alpha_1\rangle + a_2 |\alpha_2\rangle$. If we measure the expectation value of $\hat{\beta}$ in this state, we get

$$\langle\hat{\beta}\rangle = |a_1|^2 \langle\alpha_1 |\hat{\beta}| \alpha_1\rangle + |a_2|^2 \langle\alpha_2 |\hat{\beta}| \alpha_2\rangle + a_1^* a_2 \langle\alpha_1 |\hat{\beta}| \alpha_2\rangle + a_2^* a_1 \langle\alpha_2 |\hat{\beta}| \alpha_1\rangle.$$

The last two terms give the interference effect. If $\hat{\beta}$ commutes with $\hat{\alpha}$ then the nondiagonal matrix elements vanish and there will be no interference effect. For this type of experiments it is necessary that $\hat{\beta}$ and $\hat{\alpha}$ correspond to noncommuting variables. Instead of the expectation value, a measurement of the probability distribution of the results of measurement of $\hat{\beta}$ will also reveal the interference effect. If before measuring $\hat{\beta}$ we make a measurement of $\hat{\alpha}$ and the outcome is α_1 (or α_2), the state vector collapses to $|\alpha_1\rangle$ (or $|\alpha_2\rangle$). Subsequent measurements of $\langle\hat{\beta}\rangle$ will give only the first two terms and the interference effect will disappear, showing the complementarity between the interference term in $\langle\hat{\beta}\rangle$ and the which-state information about the state vector. The ME arises here because of the collapse of the state vector and not because of noncommutation between $\hat{\alpha}$ and $\hat{\beta}$.

The simplest example of complementarity of this type is realized in spin interference experiments with neutrons. Let the spin wave function of the neutron beam be given by

$$X = \chi_+ \cos(\theta/2)\, e^{-i\phi} + \chi_- \sin(\theta/2),$$

where $X_\pm$ are the spin eigenstates of $\hat{\sigma}_z$ and the spin of the beam in the state X is polarized along θ, ϕ direction. If we measure the expectation value of $\hat{\sigma}_x$, we get

$$\langle\hat{\sigma}_x\rangle = \sin\theta\, \cos\phi.$$

This is indeed an interference effect. If we measure $\hat{\sigma}_z$ to extract the which-state information, then $\langle\hat{\sigma}_x\rangle$ becomes zero, i.e. the interference effect disappears.

Other examples of class II type of complementarity can be cited from different areas of physics. In class I type of complementarity, the state vector is unimportant. It is the specific pair of variables which satisfy ME irrespective of the state of the system. But in class II type it is the structure of the state vector which is important. Depending upon a specific state vector, one can find a variable (or a pair of variables) and a measurement which will show interference and another measurement which will cause disappearance of interference. The origin of ME for class II type of complementarity is always the quantum-mechanical principle of collapse of a state vector.

So far we have discussed only the extreme situations. Either there is no which-state knowledge and there is complete interference effect or just the opposite. The question arises whether we can quantify the concepts of a degree of interference and a degree of distinguishability of the states. Indeed, using projection operators it is possible to define two operators $\hat{I}$ and $\hat{D}$ which have these properties and whose expectation values satisfy a complementarity relation.

Origin of ME in class II type of complementarity

In a recent paper Uffink and Hilgevoord[17] have made a quantitative analysis of class II type of complementarity. They introduced a measure for the indistinguishability U $(0 \le U \le 1)$ of two quantum states in a given measurement and the amount of interference I observable in the same measurement and established an inequality $U \ge I$, which they regarded as a 'quantitative expression of Bohr's claim that one cannot distinguish

between two possible paths of a particle while maintaining an interference phenomenon'.

In a similar way, but in still simpler terms, we can define I and a distinguishability parameter D (see also ref. 10) with the following considerations: Consider two orthogonal quantum states ψ_1 and ψ_2 expressed in the basis $|i\rangle$ (set of eigenvectors of some quantum-mechanical observable $\hat{\Omega}$) where some eigenvectors are common to both ψ_1 and ψ_2 and others are all different:

$$\psi_1 = \sum_1^n \alpha_i |i\rangle + \sum_{j\neq i} \alpha_j |j\rangle$$

and

$$\psi_2 = \sum_1^n \beta_i |i\rangle + \sum_{l\neq i} \beta_l |l\rangle,$$

where $|j\rangle \neq |l\rangle$ for all j's and l's. In a given measurement, we can define two operators $\hat{D}$ and $\hat{I}$ corresponding to the degree of distinguishability and the amount of interference, observable in the same measurement on a superposed state function ψ as

$$\hat{D} = |\psi\rangle\langle\psi| - \sum_1^n |i\rangle\langle i|, \quad \hat{I} = \sum_1^n |i\rangle|i\rangle.$$

The distinguishability parameter and the amount of interference observable in the same measurement can be obtained from the expectation values of $\hat{D}$ and $\hat{I}$ on the normalized superposed state:

$$\psi = [\psi_1 + \psi_2],$$

where

$$\Sigma|\alpha_i|^2 + \Sigma|\alpha_j|^2 + \Sigma|\beta_i|^2 + \Sigma|\beta_l|^2 = 1;$$

hence,

$$D = \langle\hat{D}\rangle = 1 - \sum_1^n (|\alpha_i|^2) + |\beta_i|^2).$$

So, D lies between 0 and 1. The zero value indicates complete lack of distinguishability and 1 complete distinguishability. A value of 0.6 for D signifies 60% distinguishability, implying that if $\hat{\Omega}$ is measured N times in 60% cases, we shall be able to distinguish the state and in 40% cases we fail,

Similarly,

$$I = \langle\hat{I}\rangle = \sum_1^n (|\alpha_i|^2 + |\beta_i|^2)$$

and, hence, $D + I = 1$.

When $D = 1$, $I = 0$, and vice versa; thus, D and I are complementary aspects. As an illustration consider the case of scattering of two identical particles (i.e. indistinguishable and $D = 0$); here interference of amplitude in the differential scattering cross-section is observed ($I = 1$). But for two distinguishable particles, no interference effect is observed. However, in the case of a double-slit experiment $D = 1$ does not necessarily mean that we have the which-slit information unless we make a measurement. $D = 1$ means that we have, in principle, a 100% efficient which-slit detector for the particular experiment.

We also note that the commutation relation satisfied by the two operators D and I is

$$[\hat{D}, \hat{I}] = [|\psi\rangle\langle\psi| \sum_1^n |i\rangle\langle i| - \sum_1^n |i\rangle\langle i|\psi\rangle\langle\psi|]$$
$$= \sum_1^n [(\alpha_i^* + \beta_i^*)|\psi\rangle\langle i| - (\alpha_i + \beta_i)|i\rangle\langle\psi|]$$
$$\Rightarrow \langle\psi|[\hat{D}, \hat{I}]|\psi\rangle = 0.$$

So the commutation relation does not lead to any uncertainty type of relation between ΔD and ΔI, representing the corresponding dispersions.

In all so-called wave–particle complementary experiments involving one particle at a time, time is an important parameter. We can introduce time in the above analysis and discuss the possibility whether we can have at $t = 0$, $D = 1$ and $I = 0$ and at a subsequent instant in the interference zone $D = 0$ and $I \neq 0$. A double-slit experiment closely resembles this situation. The essence of wave–particle complementarity problem is whether we can make a which-state measurement at $t = 0$ (or in the noninterfering region in the vicinity of the slits) and still get interference at a subsequent instant of time t? This is ruled out in quantum mechanics because of the collapse hypothesis.

Here we note that the operators $\hat{D}$ and $\hat{I}$ are state-dependent and the quantification of the qualitative properties of distinguishability and interference phenomenon is brought by $D + I = 1$. In complementarity phenomena the extremes, i.e. $D = 1$, $I = 0$ or $D = 0$, $I = 1$ are considered. But here the whole range is included. From the foregoing discussions it is clear that class II complementarity is consistent with the principles of QM. ME follows from collapse hypothesis of QM and in that sense we may say that class II BCP is derived from QM.

With this formulation we conclude that any experiment which claims to violate ME in wave–particle complementarity will imply some limitations of the quantum-mechanical formalism itself. This we believe is in true spirit of Bohr's original ideas.

In the following section we discuss some significant experiments on wave–particle duality in the light of the present formulation. All these experiments may be broadly

classified into three classes. The first group of experiments[2,11,18,19] are claimed to provide experimental evidence in favour of ME in wave–particle duality. In a rather novel thought experiment suggested by Scully *et al.*[11], the incompatibility between 'welcher weg' (which path) knowledge and the appearance of interference cannot be traced to any uncertainty relation. On the other hand, certain 'welcher weg' experiments[20–22] which made joint unsharp measurements of complementary observables have been used to argue that they yield 'partial particle' and 'partial wave' information and are, therefore, in conflict with the Bohrian notion of ME.

Recently, Petroni and Vigier[16] and Ghose *et al.*[23] have proposed experiments to demonstrate that a quantum-mechanical entity may display its particle and wave aspects at the same time, thereby contradicting the principle of complementarity. In what follows the significance and import of these experiments are analysed in the light of the precise statement of BCP.

Discussion of some experiments

We now take a brief look at the well-known thought experiments on wave–particle duality. In the archetypal example of the recoiling-slit arrangement Einstein hoped to devise a gedanken experiment to provide the which-path information without destroying the interference pattern of the photons; Bohr[18] pointed out that we must also treat the recoiling slits by the laws of QM. Following the arguments of Feynman[2], we note that in order to observe the interference pattern, the slits must be localized with an accuracy of the order of the slit width and the corresponding uncertainty in the slit momentum is always much greater than the momentum transfer in the scattering process. Consequently, the which-path information is not available when the photons do produce interference pattern. The entire analysis here envisages a classical particle-like passage of the photons (even when they do interfere!) through the double slit, while a correct quantum-mechanical explanation should be obtained in terms of the quantum-mechanical field function satisfying appropriate boundary condition at the slits – the concept of momentum transfer being out of place[15]. However, in the similar example of double-slit interference experiment with electrons, when Feynman intends to 'watch' the electron using scattered photon to do the spying, the interference pattern gets washed out, and Feynman's analysis invoking the uncertainty principle for the scattering process in this case may be regarded as an intuitive description not quite consistent with the formalism of QM[15].

In the interference region, the wave function describing the interfering beams may be written as the sum of two terms referring to the two slits:

$$\Psi(r) = [\Psi_1(r) + \Psi_2(r)]$$

The corresponding probability density at $r = R$ on the screen, denoted by $P(R)$, will be given by the squared modulus of $\Psi(R)$ and contains the interference term represented by $\Psi_1^* \Psi_2 + \Psi_2^* \Psi_1$. Now, if we consider two detectors 1 and 2 in the vicinity of the two slits, either making transition from ground state g to an excited state e induced by the passage of the interfering quantum object, the state of the beam plus the detector system (after entanglement) may be given by

$$\Psi(r) = [\Psi_1(r)\ |1_e 2_g\rangle + \Psi_2(r)\ |1_g 2_e\rangle].$$

For nonorthogonal detector states, partial or complete interference phenomenon is observed and no which-state information is available. In some special cases, as for detectors having coherent-state-like energy spectrum, one can have the so-called 'ein weg' (one way) knowledge, as claimed by Petroni and Vigier[16]. But if the detector states are orthogonal, the entanglement with the detector states results in a loss of coherence in interferometer and we get no interference. However, from an appropriate choice of the detector basis, as in the case of Scully *et al.*'s[11] micromaser detector, possibility of quantum erasers appears naturally[24] and the interference pattern can be retrieved. On the other hand, from a subsequent measurement on the detector state (with the aid of an atomic reader as in Scully's example) the superposed state gets collapsed and we get the which-state information.

The experiment of Petroni and Vigier

In the proposed neutron interferometry experiment[16,25] a pulsed neutron beam polarized vertically with respect to the apparatus is incident on a perfect crystal interferometer. At any instant, there is at most one neutron inside the interferometer. The beams from the beam splitter together with the coil states, described by the wave function

$$\Psi(r) = [\Psi_1(r) + \Psi_2(r)]\ |_\uparrow\rangle \ o\ |C_1 C_2\rangle,$$

are then made to pass through two radio-frequency (rf) spin flip coils, one in each arm, and are superposed beyond the final set of crystal planes.

The wave function of the emerging beams from the coils is given by[26]

$$\Psi(r) = [\Psi_1(r)\ |C_1' C_2\rangle + \Psi_2(r)\ |C_1 C_2'\rangle\ ]\ |^\downarrow\rangle$$

and retains the coherent superposition as the coil states (denoted by the C's) are nonorthogonal. The final beam thus produces an interference in the measured intensity.

There are no resonant frequencies provided by the rf field which correspond to half the energy of spin flip. If we assume that energy and momentum are conserved in each energy exchange, it implies that a spin flip occurs in either of the coils and not in both. It is also possible to obtain interference in the intensity of the detected neutrons in the same experimental set-up. However, as pointed out by Scully and Walther[27] and also by Unnerstall[26], the rf coils generate coherent states of photons and the passage of neutron through the coil cannot leave the which-path information in the coil since the coherent photon distribution remains essentially unchanged by the addition of a single photon associated with spin flip. After the passage of a large number of neutrons, the energy transferred to each coil is summed up to an amount that is detectable, and one can tell that out of N neutrons involved in the experiment, n (say) neutrons have exchanged energy with coil I and the rest $N-n$ with coil II. This is precisely what Petroni and Vigier[16] claimed as 'ein weg' information. It seems legitimate to realist physicists to infer that each neutron followed a particular trajectory or the other through the rf coils, leaving the so-called 'ein weg' information in the process. But this extrapolation is, however, not endorsed by quantum orthodoxy[26]. 'Ein weg' experiment does not contradict BCP. The only problem it creates is how one would accommodate the 'ein weg' information within the framework of the orthodox interpretation of QM.

Experiment of Ghose et al.[23]

Ghose *et al.*[23] have proposed an experiment in which single-photon states are incident on a combination of two prisms placed opposite to each other. Mizobuchi and Ohtake[28] have performed the actual experiment and verified the quantum-optical predictions outlined in the former paper. When the gaps between the prisms is larger than the wavelength, the incident 'photon states' suffer total internal reflection inside the first prism (registered by counter 1). When the gap is shorter than the wavelength, there is a possibility of their 'tunnelling' across the gap (registered by counter 2).

Since they consider the presence of 'tunnelling' to be accounted for by assigning a wave aspect to the photon, the perfect anticoincidence in the clicking of the two counters led them to claim that the 'experimental result contradicts the tenet of mutual exclusiveness of the classical wave and particle pictures assumed in Bohr's complementarity principle'.

We[23] have adopted the viewpoint of Grangier *et al.*[19] and consider anticoincidence as a signature of particle property. However, the anticoincidence observed in two detectors in a single-photon field has a totally different explanation in quantum field theory[25], devoid of the photon particle picture, a photon being just an excitation of a mode.

On the other hand, the so-called 'tunnelling' cannot be accepted as a hallmark of wave property. In that case we should consider the tunnelling of α-particle through atomic nucleus as a violation of ME in wave–particle dualism. Furthermore, while Ghose *et al.* consider the existence of evanescent waves leading to transmission of light at the critical angle as a specific wave property, Chiao *et al.*[29] described the phenomenon of 'frustrated total internal reflection' of the purely nonclassical single-photon state exploiting an analogy with particle (quantum) tunnelling through the classically forbidden region. They have also proposed an experiment to measure the photon tunnelling time using the 'particle aspect' of photon tunnelling.

According to Chiao *et al.*[29], there exists a classical limit associated with coherent states of the electromagnetic field in which the tunnelling phenomenon can be understood entirely as a classical wave phenomenon. The two arguments are, therefore, irreducible. However, it seems that tunnelling can be interpreted both as a particle and a wave property.

If we accept the interpretations of Grangier *et al.*[19] and Ghose *et al.*[23] of wave–particle duality in BCP then Mizobuchi and Ohtake's experiment[28] definitely contradicts ME. Similarly, a measurement of photon velocity on refraction in a denser medium coupled with anticoincidence will also violate ME. Again, since the probability of joint detection of more than one photon is exactly zero for an 'ideal single-photon' state, should we claim that both 'particle' and 'wave' appear in the single run of an interference experiment with 'ideal single-photon' states? One can multiply this sort of examples indefinitely[30]. On this point it is also important to note that photon enters the theory as a secondary quantity – an elementary excitation of the field. The concept of photon does not presuppose that the quantum of field energy is concentrated at a point in space, i.e. that the photon is a localized entity analogous to a very small bullet. The photon is only approximately localizable and the wave function in coordinate space is nonlocal[1]. We may also recall that Einstein always stressed the provisional nature of the light quantum postulate. In December 1951, he wrote to his friend Besso: 'All these fifty years of pondering have not brought me any closer to answering the question "What are light quanta?". Nowadays, every Tom, Dick and Harry thinks he knows it, but he is mistaken'[31]. Pushing the classical analogy too far in the photon picture may, therefore, lead to contradictions.

Some physicists are, in effect, asserting that any property for which a standard classical corpuscular theory does not exist is a wave property and vice versa. This rather simplistic interpretation of Bohr's idea is un-

tenable, for a 'particle' is not always a classical particle (when it tunnels!) and similarly a 'wave/field' may have nonclassical features. *In fact, the use of the term wave–particle duality is at the root of much confusion and QM does not guarantee the claim of complementarity between arbitrarily defined wave and particle properties.*

In this experiment the pair of properties involves no superposed state and hence no interference effect is there. Therefore, it belongs neither to class I nor to class II types of BCP. We conclude that this experiment is not suited to test BCP in its precise version.

The unsharp joint measurements[20–22] which claim to observe both interference and the path of the particle do not really fall within the compass of BCP. Bohr himself in the Como lecture discussed the wave packet description of a particle (where approximate knowledge of both momentum and position exists) as an illustration of the complementarity principle, implying that unsharp knowledge of conjugate variables does not violate BCP. Both class I and class II types of BCP imply sharp measurement.

Finally, let us summarize the situation. If we interpret the wave–particle duality aspect of BCP as a principle independent of the formalism of QM, then mutual exclusiveness becomes a doubtful proposition. In the quantum region we have neither a true classical particle nor a true classical wave. In some experiments, for some limiting value of a parameter, results can be interpreted as those of a classical particle and in the other limit as those of a classical wave. Naturally, for any intermediate value of the parameter, this type of exclusive interpretation would be impossible. Moreover, to try to designate an entity as either a particle or a wave by measuring a single property is not a very satisfactory and unambiguous procedure. A classical particle or a wave is defined by a totality of many properties.

On the other hand, we can look at BCP as focusing our attention on an important and characteristic feature of QM that every physical entity has a number of pairs of mutually exclusive variables/properties which is unknown in classical physics. Then ME becomes a defining feature of BCP. Selection of pairs of such variables/properties has to be made consistently with QM. This is really possible, as has been shown in this paper. With this modified formulation, BCP becomes consistent with QM and violation of BCP without violating QM becomes impossible.

RESEARCH ARTICLE

α-Turns in protein structures

D. V. Nataraj, N. Srinivasan*, R. Sowdhamini* and C. Ramakrishnan†

*Present address: ICRF Unit of Structural Molecular Biology, Department of Crystallography, Birkbeck College, London, WC1E 7HX, UK

The occurrence of $5 \rightarrow 1$ type of hydrogen bonds (α-turn) in proteins has been studied using a data set comprising of 107 proteins with resolution ≤ 2.0 Å. A very large majority of such α-turn segments (96%) form part of regular α-helices. The examples (84) which do not form part of an α-helix are termed 'isolated α-turns' and are grouped into two major families and seven minor groups along with two isolated examples based on the similarity of conformational angles. The family with large number of examples (50) have (φ, ψ) angles close to an α-helix and hence belong to the class of the shortest α-helices. The 'end to end' distances of these α-turns vary between 4.7 and 6.7 Å, the range being nearly the same as that of α-helices. The propensity calculations show that some amino acids such as Glu, Ser and Thr have statistically significant higher preferences to occur in α-turns than in α-helices. In addition to the $5 \rightarrow 1$ type, the residues in the α-turn are involved in hydrogen bonds with other parts of the chain. The residues are in general more hydrophilic compared to those in α-helices. In many cases (70%) the α-turn occurs at the ends of extended strands, and whenever it occurs at the loop regions connecting two extended strands, it brings about a hairpin bend.

POLYPEPTIDE chain reversal is an essential feature in bringing about the globular shape of proteins. Turns are also associated with various aspects of protein function[1-3]. The direction of the main chain can be reversed by characteristic conformations at a single amino acid residue (γ-turns[4,5]) or at two residues (β-turns[2,6,7]) or by longer loops[8-10]. Both γ- and β-turns are locally stabilized by hydrogen bonds in the main chain. The $3 \rightarrow 1$ hydrogen bond in the γ-turn is formed between carboxyl oxygen at position i and amide at position $i+2$, with the turn forming residue at the position $i+1$. Most β-turn types are stabilized by a $4 \rightarrow 1$ hydrogen bond between carbonyl oxygen at position i and amide at position $i+3$.

These two kinds of turns occur frequently in globular proteins, with β-turn being one of the more common substructures[11-14]. In this communication, attention is drawn to 'three-residue segments' locally stabilized by a $5 \rightarrow 1$ hydrogen bond between carbonyl oxygen at position i and amide at position $i+4$, reversing the course of the polypeptide direction. The analysis of a large number of known three-dimensional structures of proteins reveals that such a local chain reversal is a common occurrence. This class of turns is referred to as α-turns since the hydrogen bonding pattern is the same as in the α-helix. A schematic diagram of an α-turn is shown in Figure 1. The present analysis shows that α-turns can have different characteristic main chain conformational angles and amino acid preferences. They connect regular secondary structures and quite often act as linkers of two β-strands.

Materials and methods

Data set used

The data set used in the present study consists of a set of 107 proteins whose coordinates are available in Protein Data Bank[15,16]. The choice of the set has been guided by the condition that their resolution is 2 Å or better, and the cut-off percentage of the sequence homology between any two proteins in the set is not more than 40. Also in the case of proteins having multiple chains with the same sequence, only one chain has been considered.

Identification of α-turns in proteins

Since the $5 \rightarrow 1$ hydrogen bond is the crux of the

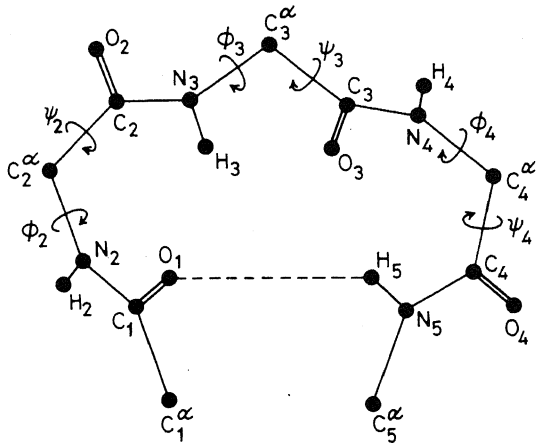

Figure 1. Schematic diagram of an α-turn, occurring in a system of four linked peptide units. The designations of atoms and torsion angles involved are also marked.

α-turn, the proteins are examined to find out all tetrapeptide segments which have this hydrogen bond. The hydrogen bond criteria used for this purpose is as follows.

The hydrogen bond length l (N . . O distance) must lie in the range 2.6–3.6 Å and the hydrogen bond angle θ (H–$\hat{N}$ . . O) should be less than or equal to 40°. (The criteria used here are slightly relaxed compared to those that have been normally used in other conformational studies. For example, in small molecules, where the crystal structures are accurately determined, the hydrogen bond length is in the range 2.6–3.2 Å and hydrogen bond angle is usually less than 30° (ref. 17)). The reason for relaxing the criteria is the lesser accuracy in protein structure determination as well as the lack of information on the positional coordinates of hydrogen atoms.)

As the hydrogen positions are not available in the coordinate data of Protein Data Bank (PDB) (with few exceptions, however), the H-bond angle θ could not be readily evaluated. For this purpose, the positional coordinates of the amide hydrogens have been computed by geometrically fixing the hydrogen atoms at the corresponding nitrogen atoms in the plane of the peptide unit using the ideal bond angles around the nitrogen atom[18].

Results and discussion

Using the H-bond criteria mentioned above, it has been possible to identify 2525 tetrapeptide segments in the proteins which have $5 \rightarrow 1$ hydrogen bonds. These examples obviously include those segments which are part of α-helices, since an α-helix is a succession of $5 \rightarrow 1$ hydrogen-bonded segments. The removal of the segments that are part of an α-helix has been done by a combination of (φ, ψ) criteria and by inspection. The conformations at (φ, ψ) at the five α-carbon atoms are designated as R or X, whether or not it lies in the range -130 to 0° for φ and -130 to 30° for ψ. If there are four **successive** R's (i.e. the designations at the four α-carbon atoms i, $i+1$, $i+2$ and $i+3$ or at $i+1$, $i+2$, $i+3$ and $i+4$ are R's) then it is treated as forming a part of α-helix. The examples which still remain are further examined by inspection to remove any possible borderline cases. On removing those examples which form part of an α-helix, there were 84 examples which remained, and these can be considered as isolated α-turns. (The corresponding numbers of examples for β- and γ-turns are 383 and 210, respectively). The PDB codes of the proteins and the segments in which these α-turns occur are listed in Table 1 *a*. These examples occur in 51 of 107 proteins of the total set. The number of examples of these α-turns in a protein varies from one to four except in the protein phosphate dehydrogenase (1gd1), where there are five examples.

In those proteins which contain two or more examples, the segments are well separated from one another. The two examples occurring in protein flavodoxin (1fx1) are somewhat unique in that the two α-turn segments 71–75 and 72–76 overlap, resulting in a longer segment 71–76. The individual segments are, however, conformationally different and the full segment 71–76 is not α-helical.

For those segments that have been picked up as α-turns, the (φ, ψ) angles at the three intervening α-carbon atoms C_2^α, C_3^α, and C_4^α have been computed and analysed.

Conformational analysis

The (φ, ψ) angles at each of the three C^α atoms have been plotted on the (φ − ψ) plane and these are shown in Figure 2 *a–c* corresponding to C_2^α, C_3^α, and C_4^α, respectively. These plots are first analysed independently and then used collectively to arrive at families of α-turns.

In Figure 2 *a*, which corresponds to the conformation at C_2^α, four groups of points are plainly seen, one of them being a dense cluster having a very large number of examples near the right-handed α-helical region designated as α_R. Of the remaining three clusters, one which occurs in the left-handed α-helical region is designated as α_L. The third, having few examples, occurs near the extended conformational region and has been designated as E. The fourth cluster which has eight examples occurs in a region that can be considered as inverse to the cluster E and has been denoted as E′. (Seven out of these eight examples are Gly and the odd member out is the residue Asp, A70 in the protein ovalbumin[19]

– Isolated examples.

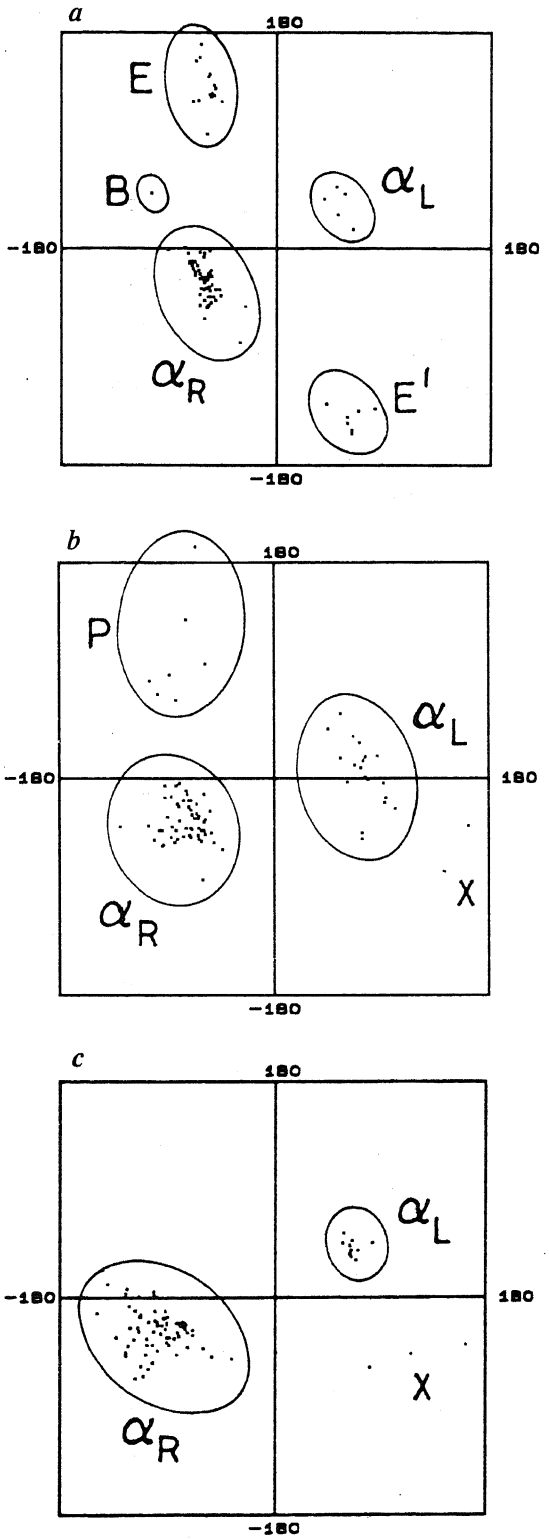

Figure 2. The (ϕ, ψ) plot of the conformational points at the three α-carbon atoms in the examples of isolated α-turns: *a*, at C_2^α; *b*, at C_3^α; *c*, at C_4^α. The clusters in each of the plots are also marked, with their designations indicated.

(1ova)). In addition to this, there is a solitary example at (– 106°, 46°) (referred to as B, as this occurs in the bridge region of ($\phi - \psi$) map[20]). Thus, the distribution at C_2^α points to the possibility of at least four major families.

Figure 2 *b*, which corresponds to the ($\phi - \psi$) distribution at C_3^α, shows three prominent clusters. The one which lies in the α_R region comprises a majority of the points. The other two clusters are slightly more scattered as compared to the α_R region. One of these occurs in the right half of the map spanning across the ϕ-axis. This is denoted as α_L. The third one occurs in the left top quadrant of the map, in which the extended conformations normally occur. But five of the seven points are clustered closer to the poly proline region of the map (– 60°, 120°) than the $\psi = 180°$ axis. Hence, we have preferred to use the symbol P rather than E to denote this cluster (see Figure 2 *a*). In addition to these, there are two isolated points occurring near the right edge of the map which are designated as X.

Figure 2 *c*, which shows the distribution of (ϕ, ψ) at C_4^α, has two clusters, a major one in α_R and a minor one in α_L region. In addition to these there are three isolated points (X) occurring in the right bottom quadrant of the map. It may be worthwhile to note that, there are no points in the 'extended' region of the map as contrasted with Figure 2 *a* and *b*.

Classification into families

As the formation of $5 \rightarrow 1$ hydrogen depends on the *combined set* of (ϕ, ψ) values at the three α-carbon atoms *in a collective way*, the examples have been carefully looked into and grouped into different families such that members of the same family have nearly the same combination of (ϕ_2, ψ_2), (ϕ_3, ψ_3), (ϕ_4, ψ_4). This exercise has revealed that a large fraction of examples (60%) form one major family (designated as F1). The other families contain relatively small number of examples. The family which has the next highest number (9 examples) is designated as F2. Apart from these, seven more groups can be identified, having 2–5 examples. In view of the small number of examples, these will be referred to as groups g1–g7. In addition, there are two isolated examples. The details pertaining to the members in various families and groups are given in Table 1 *a*. The (ϕ, ψ) plots are shown in Figure 3 *a–k* and the average (ϕ, ψ) values at C_2^α, C_3^α and C_4^α for each category are given in Table 1 *b*.

The family F1, which has a bulk of examples, is characterized by α_R conformations at all the three carbon atoms C_2^α, C_3^α and C_4^α. Thus, this family, which can be designated as 'α-helical α-turn' represents the shortest helix that can possibly occur. The (ϕ, ψ) values at the two α-carbon atoms immediately preceding and succeeding the turn, i.e. at C_1^α and C_5^α, are shown in Figures 4 *a* and *b* (absence of points in the α_R region in this figure confirms the isolated nature of the α-turn in these

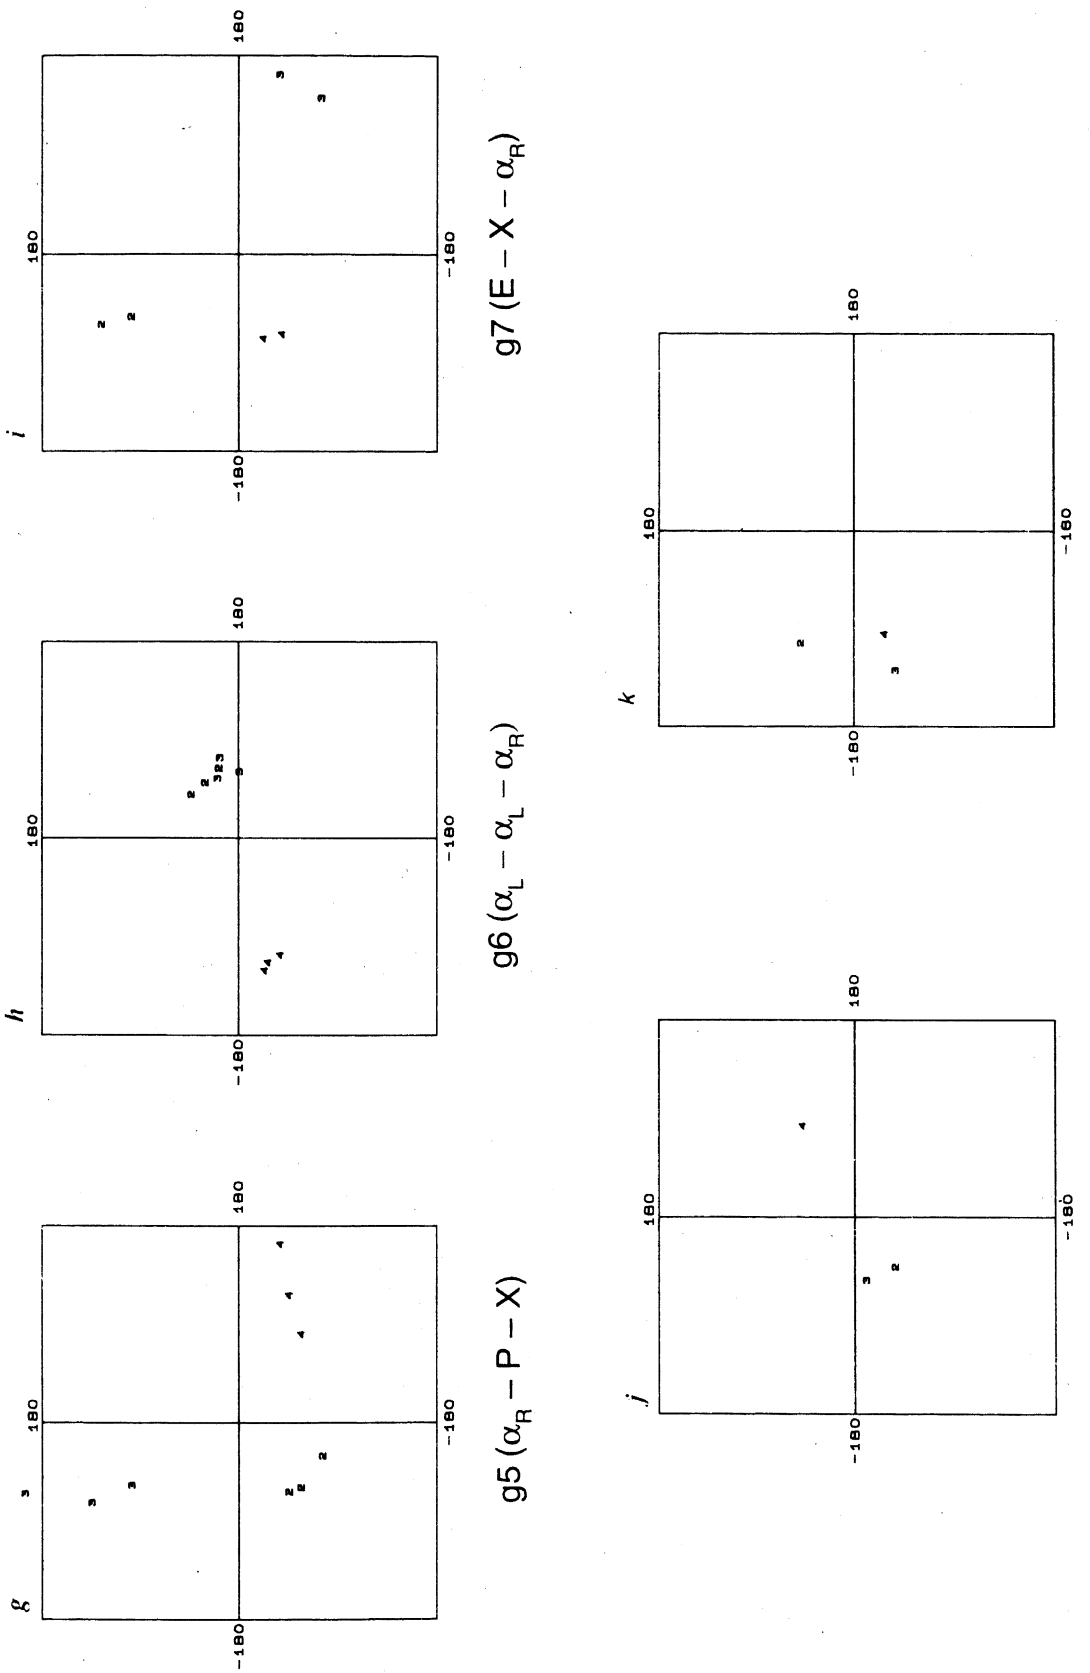

Figure 3. *a–k*, The plot of (ϕ, ψ) at the three α-carbon atoms in the α-turns in proteins grouped into different categories, based on conformational similarity. The conformational points corresponding to C_2^α, C_3^α and C_4^α are marked as 2, 3 and 4, respectively. The designation of each category is also marked.

Figure 3 *g–k*.

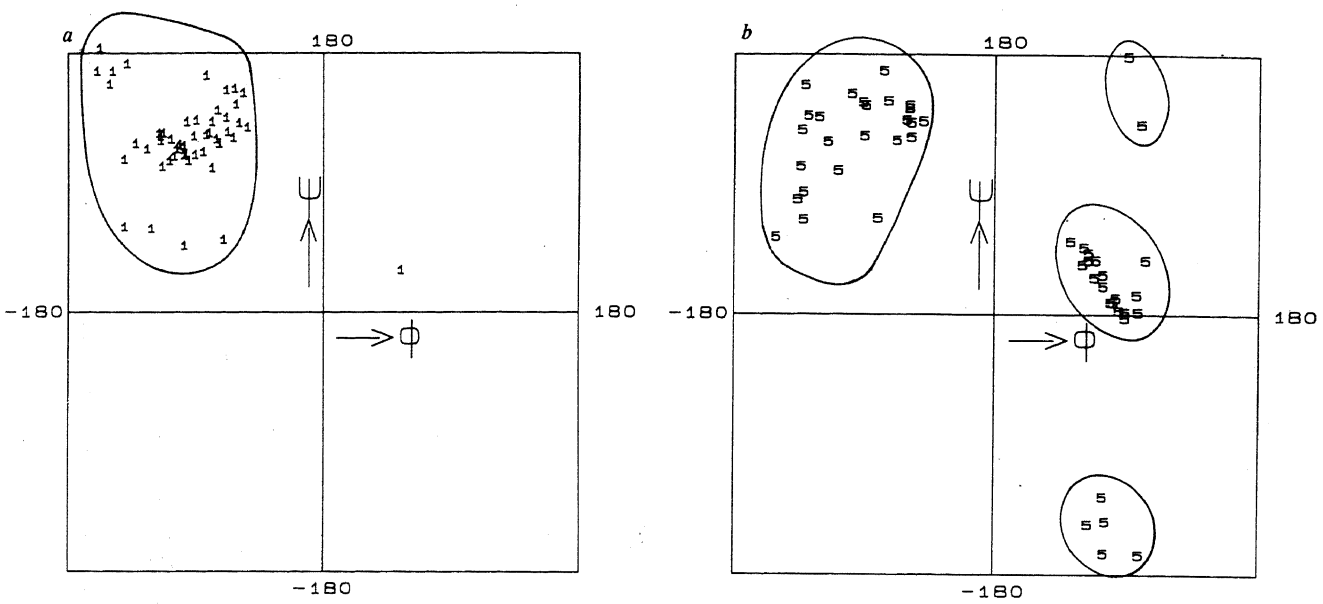

Figure 4. Plot of the (ϕ, ψ) values at the two α-carbon atoms immediately preceding and succeeding the α-turn in the examples of family F1. The clustering is also marked: *a*, at C_1^α; *b*, at C_5^α.

examples). It is very interesting to note that all the points except one in Figure 4 *a*, occur in the same quadrant of the (ϕ, ψ) plane, with a cluster near the extended conformation. There are two major and one minor clusters observable in Figure 4 *b*. One of the two major clusters occurs close to the extended region and the other in the α_L region. The minor cluster occurs in the inverse extended region (similar to the one designated as E′ in Figure 2 *a* and all these are glycyl residues). Thus, it is possible to have three motifs (while the term family is used to denote the segment with similar values at (ϕ, ψ) C_2^α, C_3^α and C_4^α, the term motif is used to denote the segment with similar (ϕ, ψ) values at all the five positions C_1^α to C_5^α) for this family, which can be represented by ($\beta - \alpha_R - \alpha_R - \alpha_R - \beta$), ($\beta - \alpha_R - \alpha_R - \alpha_R - \alpha_L$), ($\beta - \alpha_R - \alpha_R - \alpha_R - E'$), and the isolated example, which occurs in the protein enolase[21] (segment 102–106) can be designated as ($\alpha_L - \alpha_R - \alpha_R - \alpha_R - E'$).

The next largest family F2 has only 11 examples and is formed by conformational combination of E, α_L and α_R. This and other groups show that different combinations of (ϕ, ψ) at the three α-carbon atoms do occur in proteins, resulting in the formation of $5 \rightarrow 1$ hydrogen bonds to stabilize the local nonhelical regions. The designations of the families/groups are given in Table 1 *b*. Stereo diagrams of one representative example from each of the families F1, F2, groups g1–g7 and the two isolated examples are shown in Figure 5 *a–k*.

In the sections that follow, the different characteristics and features of α-turns are examined in detail.

End-to-end distances

The end-to-end distance (C_1^α–C_5^α) in the examples of α-turns varies between 4.7 and 6.7 Å. The distribution among the various families/groups in the different ranges is given in Table 2. (There are two examples of α-turns occurring in the protein 2cyp[22] (segment 35–39 belonging to F1) and in the protein 1gox[23] (segment 345–349 belonging to g1), which have end-to-end distances lying outside this range of 4.7–6.7 Å. The end-to-end distance is 4.2 Å in the former and 7.0 Å in the latter.)

The major family F1 has examples throughout the range, indicating flexibility in the chain segment. Groups g2, g3, g4 and g6 have smaller ranges of end-to-end distances (< 5.7 Å) and these groups have served the purpose of bringing the two ends of the segments much closer. On the other hand, the three members of group g5 are characterized by distances in the higher end of the spectrum (5.7–6.7 Å). It is worthwhile to mention that the computation of the corresponding distance in the various α-helical segments occurring in the data set shows that 92% of the examples lie in the range 4.0–7.0 Å (the ideal value for α-helix being 6.2 Å).

Propensity of amino acids to occur in α-helical α-turn

As mentioned earlier, the family F1, which contains α-helical α-turns, comprises a majority of examples. Since this is the shortest helix that can be formed, it

– Isolated examples.

may be interesting to compare propensity values of amino acids involved in such turns. The propensity of occurrence of an amino acid at the specified position of the α-turn is given by

$$p_j^k = \frac{f_j^k}{F_j},$$

where f_j^k is the fraction of amino acid residue of type j at position k and F_j is the fraction of the same amino acid in the complete data set.

Using the above formula, the propensity of these amino acids to occur in the positions $i+1$, $i+2$, $i+3$ of the α-helical α-turn have been computed. These along with average propensity are given in columns 2–5 of Table 3. It is evident that four amino acids Cys, Glu, Ser and Thr show higher propensity (> 1.2) to occur in α-turns. (These are shown in bold in the table.)

Statistical significance of the propensity values has been determined using the *d*-test[11]. The statistic d is given by

$$d = \frac{(n \times f_j^k) - (n \times F_j)}{\sqrt{n \times F_j \times (1 - F_j)}},$$

where n is the number of examples in F1.

The amino acids with statistically significant propensity values for 5% tail ($d > 1.97$) are shown with an asterisk in Table 3. Of the four amino acids with high propensity values, only three (Glu, Ser and Thr) are seen to be statistically significant. The amino acid Cys, in spite of showing a high propensity value, is not statistically significant (probably due to the small sample size).

Since the α-turn when repeated, leads to an α-helix, it will be interesting to compare these propensity values with the corresponding ones for α-helical segments in proteins. The propensity values for amino acids to occur in an α-helix as computed using the data set used are

*Statistically significant as per *d*-test.

given in column 6 of Table 3. The values are in good agreement with those reported earlier by other workers[24,25]. The amino acids that exhibit high propensity (> 1.2) are shown in bold. (Glu, Met, Gln, Lys and Arg). It is interesting to note that, except for Glu, none of the other amino acids show large propensity both for α-helix and α-turn. This shows that the *amino acids that have larger propensity to occur in α-turn have no greater tendency to occur in α-helices and vice versa.* This qualitatively lends an explanation to the isolated nature of the α-turns. The above analysis shows that among the 20 amino acids, Ser and Thr have formed α-turns in spite of their low propensity for α-helices.

Another way of looking at the α-turns is to consider them as an overlap of two successive β-turns ($i \rightarrow i+3$ and $i+1 \rightarrow i+4$), with the β-turns being of type I and/or type III. Identifying β-turns by the criteria of Ramakrishnan and Srinivasan[26] (and not necessarily by the existence of $4 \rightarrow 1$ type hydrogen bond), 42 out of 50 examples of family F1 fall under this category (in 27 examples two type I β-turns overlap and in 15 examples type III and type I β-turns successively overlap). The propensities of these amino acids to occur in various types of β-turns have been reported by Wilmot and Thornton[11]. The interesting aspect is that the propensities of the amino acids Cys, Ser and Thr (which show greater propensity for α-turns) are also greater than 1.0 for type I β-turns. A further analysis shows that less than one-third of the overlapping β-turns (42 out of 153) alone form the α-turn.

Since all the 20 amino acids have occurred in α-turns, it would be more appropriate to look at the product propensity of the triplet of amino acids that occur at C_2^α, C_3^α and C_4^α (the product propensity being the product of the individual propensities) and select those triplets that may have a better preference to occur in α-turns as compared to α-helices. This is done by evaluating a quantity ΔP, which is the difference between the product propensity for an α-turn and the product propensity for α-helix. The distribution of ΔP is shown as a histogram in Figure 6. It can be seen that, though the peak occurs around 0, there are few triplets that occur in α-turns which have a large ΔP. Those with $\Delta P > 4.0$ are listed in Table 4. In the six distinct triplets listed in Table 4, Thr, Cys and Ser contribute 78%, which is to be expected since these are the predominantly high-propensity amino acids for α-turns.

Other hydrogen bonds of residues involved in α-turn segment

Since the isolated α-turns do not have consecutive hydrogen bonds to stabilize the segment, it may be interesting to find out whether these α-turn segments are involved in hydrogen bonds with other parts of the chain. On doing this, it was found that except in two examples, the segment is invariably involved with other hydrogen bonds (in addition to the $5 \rightarrow 1$ hydrogen bond). In fact, of the 252 residues in the α-turns (84 examples with three residues in positions $i+1$, $i+2$ and $i+3$), 178 (71%) act either as a donor or an acceptor for hydrogen bond. It is interesting to note that 79 out of 84 (94%) residues in position $i+3$ take part in hydrogen bonding. (The corresponding values for residues in positions $i+1$ and $i+2$ are 61% and 57%, respectively).

*Cut-off is 4.0.

Hydrophobicity of residues in α-turns

Another aspect that can be looked into is the nature (hydrophobic or otherwise) of the residues involved in the α-turn examples of family F1. Using the consensus values of Eisenberg[27], the average hydrophobicity of the α-turn segments (H_α^t) are evaluated (i.e. average of the hydrohobicity values of the residues at positions $i+1$, $i+2$ and $i+3$). This distribution is shown in Figure 7 *a*. Figure 7 *b* gives the corresponding distribution of hydrophobicity using the residues occurring in α-helices in the data set. It is clear that the residues involved in the isolated α-turns are more polar (hydrophilic) compared to those in α-helices. This would mean that these α-turns are more likely to occur on the surface, accessible to the solvent. This is in agreement with the now well-known concept[2] that the turns in protein usually tend to be on the surface as compared to the other longer secondary structures such as helices and sheets.

Location of α-turns in proteins

The α-turn, being a small segment with a well-defined geometry, can act as a linker between two secondary structural segments in proteins. This aspect has been looked into by examining the proximal secondary structure that (giving an allowance of maximum of four residues on either side) occurs on either side of the α-turn. The secondary structures were identified by examining the contiguous occurrence of representative (ϕ, ψ) values[26]. The results are tabulated in Table 5, in which H stands for helix, E for extended strand. (The commonly used notation is β-strands.) In an earlier communication[28] it has been shown that some of the β-strands are not involved in the formation of the β-sheet. The notation β_s is used to designate those which are involved in forming the β-sheet and β_i those which did not. We have preferred to use the notation E-strands since (i) these have been identified with the criteria that the (ϕ, ψ) values in the segment all lie in the

'extended conformational region' of Ramachandran map and (ii) no distinction has been made between β_i and β_s strands and U (uncharacterized) for other segments.

It can be seen from the table that there are examples for all the possible combinations. The maximum number of examples (19) occur for EE linkers (E–α_T–E). In fact, in about 70% of the examples the α-turn either precedes or succeeds the E-strand. This points to the tendency of α-turns to occur at the ends of extended strands.

The EE linkers are further examined from the point of view of immediate local chain reversal. Very interestingly, in 17 of these 19 examples, the α-turn occurs at the loop regions of β-hairpin. Even in the two cases 1sn3 (α-turn segment 7–11) and 2rsp (α-turn segment A46–50), the E-strands adjoining the α-turn though not forming a sheet are antiparallel in orientation and hence the full stretch can be considered as a hairpin bend without intermolecular hydrogen bonds. These are listed in Table 6, along with the α-turn families/groups to which they belong. Nine of these belong to family F1 and the remaining are distributed among the various groups. The β-hairpins occurring in proteins have been grouped into four classes by different workers[29–31]. Following the definition given by Pavone[30] the classes to which these linkers belong to have also been identified and these are also given in Table 6. Examples are found belonging to all the four classes (I, II, III and IV), with class IV having the maximum number (11).

Four examples, one in each from the families F1 (1cox)[32], g1 (1gcr)[33], g4 (3apr)[34] and one of the isolated examples (2fbj)[35] are shown in Figure 8, which brings out this aspect pictorially.

The α-turns which form linkers between other secondary structures (viz. (i) helix and helix, (ii) helix and strand and (iii) strand and helix) do not exhibit any conspicuous pattern or uniformity.

The oxygen atom taking part in the hydrogen bond is explicitly shown. *a*, segment 388–399 of the protein 1cox (α-turn 391–395: family F1); *b*, segment 41–58 of the protein 1gcr (α-turn 47–51: group g1); *c*, segment E5–E21 of the protein 3apr (α-turn E11–E15: group g4); *d*, segment L160–L172 of the protein 2fbj (α-turn L166–L170: isolated example).

Conclusion

The present study shows that the proteins do contain 5 → 1 hydrogen-bonded α-turns which do not necessarily form part of a larger secondary structure such as α-helix. The fact that the number of such examples of isolated α-turns is small as compared to β-turns, points to the fact that in these examples, α-turns have, for some reason, been preferred over the more populous β-turns. The small but significant number of examples of α-helical α-turns indicate that, in these cases, (i) either the α-helix which has been initiated has not progressed or, alternatively, (ii) the α-helix thus formed by the α-helical α-turn has not been able to propagate itself in either direction.

Since these examples occur in different types of proteins, the reason for these short α-helical α-turns may not lie so much in the functional/folding aspects of the protein as in the combination of residues in the α-turns as well as those which immediately precede and succeed these turns. In any case the isolated α-turns deserve to be considered as a secondary structural feature, though of a minor nature.

Task activation of the human brain studied in real time by functional magnetic resonance imaging

N. R. Jagannathan* and P. Raghunathan

Department of Nuclear Magnetic Resonance, All India Institute of Medical Sciences, Ansari Nagar, New Delhi 110 029, India

This paper describes our initial results on functional brain mapping using a whole-body clinical magnetic resonance (MR) scanner operating at 1.5 T and having no echo planar imaging capability. The focus is on the effects of motor cortex stimulation of normal volunteers using a circularly polarized head coil when a gradient echo pulse sequence is employed. The study demonstrates the technical feasibility of functional MR imaging by using conventional gradient echo sequence and equipment.

MAGNETIC resonance imaging (MRI) is a well-established noninvasive clinical diagnostic tool which produces a spatial display of hydrogens present in the human body and provides a high-resolution morphological picture of the anatomy with superior contrast resolution[1]. Recent developments in MRI methodology have demonstrated the possibility of observing human brain function[2–15]. 'Functional' imaging (fMRI) has great potential for assessing individual pathophysiology and for characterization of human brain functions such as language, learning, memory, task activation, etc.[16]. Using the echo planar imaging (EPI) technique, Belliveau *et al.*[2] described the measurement of blood volume during visual activation, which not only opened up exciting new possibilities in the study of brain physiology but also provided a unique and challenging tool for neuroscience. Since then, several research groups have demonstrated that functional imaging of the human brain was feasible on their conventional MR system, where EPI capabilities were not available[6–15].

In this paper, we present our initial experimental results on task activation studies using the fMRI technique. Our studies have been carried out on normal volunteers using a Siemens MAGNETOM 63SP-4000 whole-body scanner. Our objective was to evaluate and demonstrate the feasibility of such studies on our 1.5 T whole-body scanner, using the FLASH sequence[17].

Experiments were performed on the 1.5 T superconducting whole-body scanner using a circularly polarized head coil. Magnetic field shimming with all first-order coils was performed by means of global shimming for each subject, achieving typical line widths of about 15 Hz. Scout images, one in each orthogonal plane, were initially obtained. Later, multislice T_1-weighted images in the sagittal, and in some cases coronal, planes were obtained using the standard spin echo sequence with an echo time (TE) of 15 ms, repetition time (TR) of 520 ms, a 256×256 matrix and a slice thickness of 5 mm. Using these images as an anatomic guide, appropriate tilted planes were then selected for task activation studies. One or more of the tilted axial planes passing through the primary motor and sensory cortex (Figure 1) were selected. The pulse sequence used was a conventional two-dimensional, refocused gradient echo FLASH sequence[17,18] with TR = 90 ms, TE = 60 ms, flip angle = 40°, matrix size 64×128, field of view (FOV) = 200 mm, and slice thickness = 8 mm.

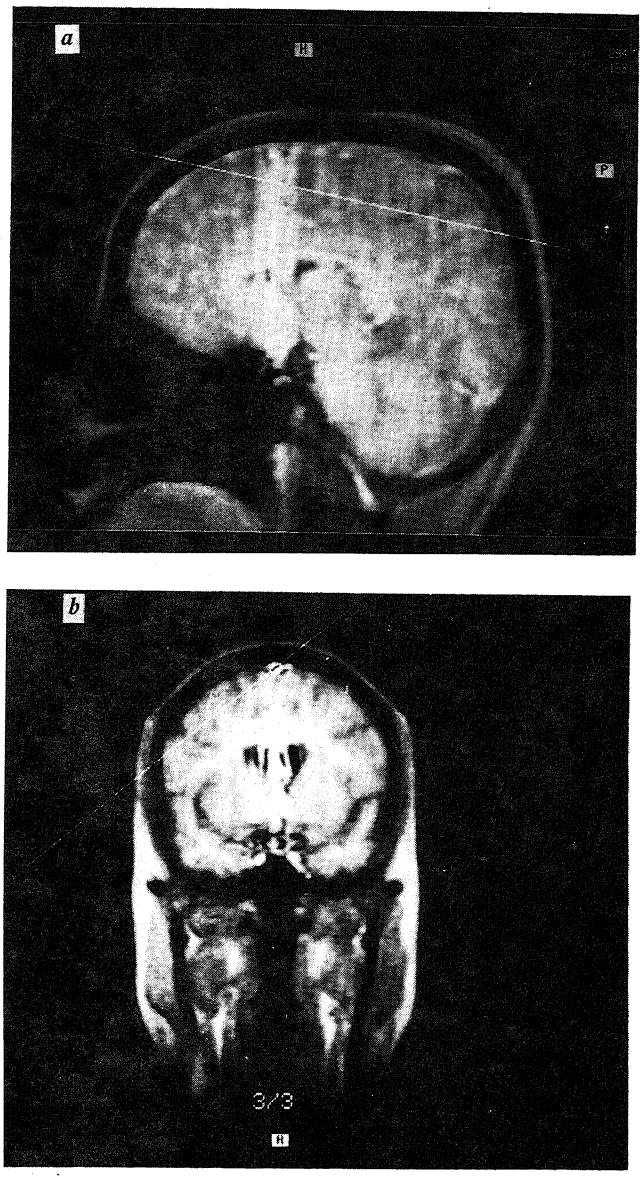

Figure 1. Proton MR images illustrating the orientation of the axial planes selected for task activation studies: *a*, for observing both the hemispheres of the brain simultaneously; *b*, for observing the left-hand movement on the right hemisphere of the brain.

*For correspondence.

These were optimized parameters, selected on the basis of a number of preliminary experiments. The percentage increase in signal intensity varies approximately linearly with TE; however, due to T_2^* processes, the overall signal intensity in both the control and activated images are known to decline with TE for a chosen tip angle of the RF pulse[9]. The maximum signal intensity increase in absolute terms occurs at a TE value approximately equal to T_2^*, which is around 66 ms in the activated region at 1.5 T (refs 6, 9). Our preliminary experiments also gave similar results and hence a TE value of 60 ms was used for all fMRI studies.

The hand task activation consisted of the volunteers ($n = 4$) either holding a sponge in the left or right hand and squeezing it repetitively, or performing finger-to-thumb movements. The rate and force of the squeezing of the sponge and finger-to-thumb movements were not controlled. Data were collected in blocks of 10 control images (i.e. in the task-free resting state), followed by 10 obtained during task activation (Figure 2). This procedure was repeated 4 or 5 times for each hand movement. When the axial plane shown in Figure 1 *a* was used, both left and right motor cortices were observed simultaneously. For this study, the volunteers ($n = 3$) held the sponges in both the hands and were asked to squeeze them simultaneously.

The MR images were reconstructed in the standard manner. Necessary postprocessing such as addition and subtraction of images was carried out using specialized software packages.

Figure 3 *a* shows an oblique T_1-weighted spin echo image of the anatomy of the selected section for subsequent monitoring of task activation, obtained using Figure 1 *b* as a pilot image. Figure 3 *b* shows the effects of left-hand movement; the appropriate cortical activity can be clearly seen near the sulcal wall. For observing both left and right motor cortices simultaneously, an axial oblique through a sagittal section was used as shown in Figure 1 *a*. Figure 3 *c* shows one such activated image when the volunteer was asked to activate both the hands, as described earlier. In general, the maximal signal intensity increase for the appropriate slice thickness used has been computed to be around 3–8%.

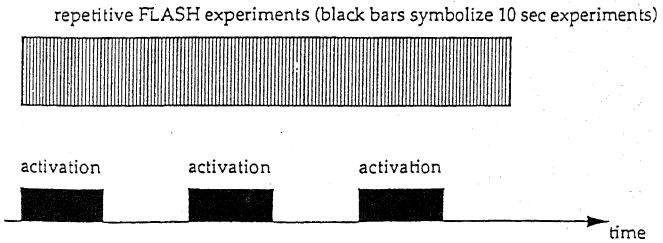

Figure 2. Experimental protocol for motor cortex activation. During 'activation' the volunteer performs the task of squeezing the sponge or finger-to-thumb motion.

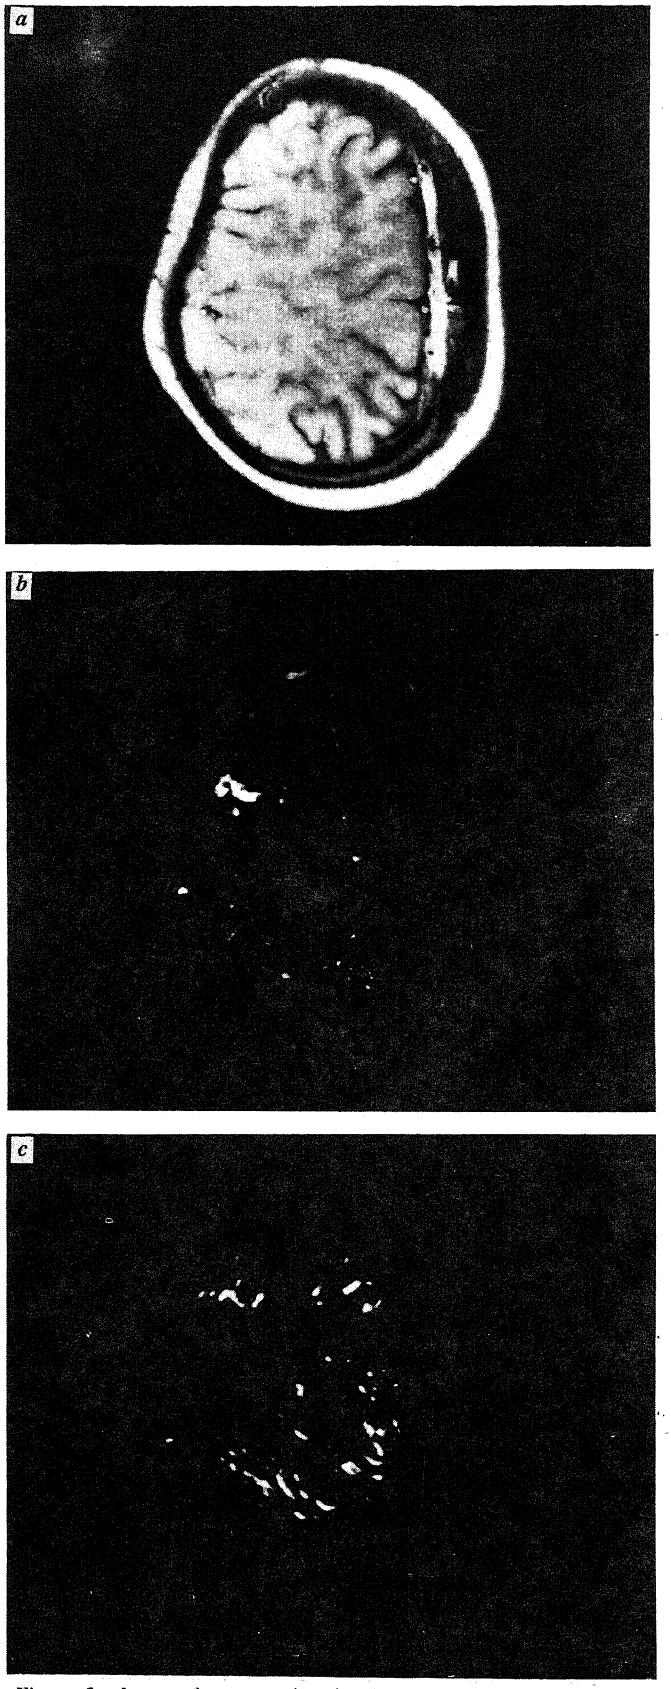

Figure 3. Images from a study of task activation obtained using the section orientation shown in Figure 1 *b*. *a*, Anatomy of the selected section. *b*, Effects of activation of the left-hand task. *c*, Effects of activation during the task performed using both the hands simultaneously.

The images shown in Figure 3 *c* are suitable for simultaneous examination of both left and right motor cortices. However, oblique planes through one hemisphere of the brain are preferable for viewing the detailed functional anatomy of the primary motor and sensory cortices. It is clear from Figures 3 *b* and *c* that activation is seen in grey matter of the sulcal walls, with little or no apparent effect in the intervening white matter[9]. In addition, the region activated by the hand movement task can also be precisely defined and related to specific gyri and sulci at a deeper level by following the activation down through successive sections using the three different planes shown in Figure 4 *a*. The set of images thus obtained from the right hemisphere of the brain from the superficial and middle planes are shown in Figures 4 *b* and *c* for the left-hand movement (see figure caption for details). As is seen clearly, the activation manifests itself as a hyperintense patch in the grey matter on both walls of the central sulcus. Other minor signal enhancement regions are also observed, showing that the area of activation is not confined to the walls and to the central sulcal region. These enhancement regions are believed to be associated with venous microvasculature in the grey matter[3].

The activation experiments were performed by first acquiring a set of 10 'activated' images – series A (during activation) – followed by 10 corresponding control rest images – series B (without any hand movement). This procedure of 'activity' (series A) followed by 'rest' (series B) was repeated 3 or 4 times. The image processing algorithm consists of adding together all the images of set A and producing a composite 'ACTIVE' image A. Then all images of series B, corresponding to rest period (no activation), were added together to produce a composite 'REST' image B. Finally, the algorithm takes the difference (A–B), and displays it as the 'functional MRI' image C. In this manner, the activation images shown in Figures 3 and 4 are the difference images obtained after 3 or 4 cycles of rest and activity. The accumulation of each data set takes about 800 s. The increase in signal intensity varied between 3 and 8%, depending upon the slice thickness used. However, the percentage signal intensity change depends on a number of factors such as partial volume effects, T_2^*, and other parameters used, such as the echo time, repetition time, slice thickness and, of course, the field strength. Intensity variations have also been known to occur if the postprocessing procedure is not correct. Subject movement during activation experiments may correlate with the task being performed and signal changes noticed may then be mistaken for evidence of brain activation[13]. Recently, several reports have appeared in the literature on these aspects and methods have been suggested to overcome these[19,20].

In our work, proper care has been taken regarding

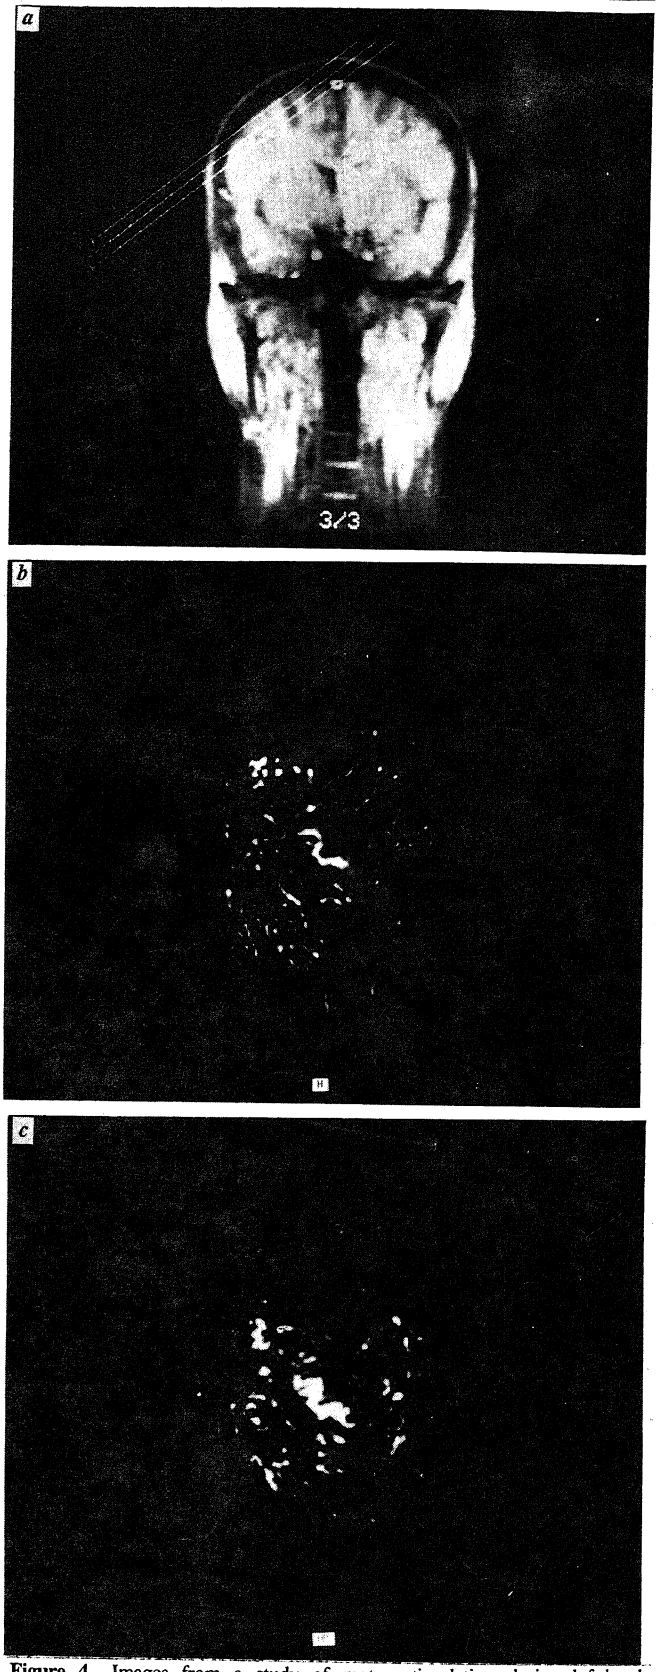

Figure 4. Images from a study of motor stimulation during left-hand movement task. *a*, The different contiguous planes selected; superficial, middle and deep. *b*, Activation in the superficial plane. *c*, Image from the middle plane. (The deep plane contains no image enhancement, denoting that it was not activated in hand movement and hence is not shown.)

subject movement during data acquisition to reduce motional artefacts. In addition, a set of 10 control (rest) images (with no activation – called set X) followed by another set of 10 control (rest) images (set Y) were separately acquired. All the images of set X were added together, producing a net 'REST' image X; similarly, all the images of set Y were added to produce another composite 'REST' image Y. The difference image, i.e. X–Y, was then obtained, which showed no signal enhancement in the plane selected, thus justifying that artefactual effects had been kept down to a minimum in executing our postprocessing algorithm.

The increase in local signal intensity observed in Figures 3 and 4 may be explained on the basis of our understanding of the blood-oxygenation-level-dependent (BOLD) mechanism whereby changes in neuronal activity affect the MR signal[21,22]. During task activation, brain stimulation takes place with increased blood flow, and oxygen delivery to the activated region exceeds the metabolic need[23]. The rise in blood supply seems to exceed the rise in oxygen consumption, leading to a local decrease in the ratio of deoxyhaemoglobin to oxyhaemoglobin[21,22]. Deoxyhaemoglobin is a paramagnetic substance and acts as an effective endogenous contrast agent. Moreover, a decrease in deoxyhaemoglobin concentration also decreases the vessel tissue susceptibility differential (leads to increased T_2^*), allowing increased spin coherence and thus increased signal while using a gradient echo sequence such as FLASH.

The functional MR images presented in this paper demonstrate that it is possible to use a conventional 1.5 T MR imager without echo planar capability for monitoring the brain functions if a gradient echo pulse sequence such as FLASH is employed. The application potential of fMRI is enormous in the area of neurosciences for assessing individual pathophysiology and for characterization of several brain functions[16] related to language[24], memory etc. In addition, it may also have important applications in neurosurgery. Identification of the anatomical relationship of a functional area to a tumour (which often distorts and displaces normal anatomy) is a great help to the neurosurgeon while planning the surgical approach and to preserve these primary areas during therapeutic operations[9].

Radon precursory signals of Chamba earthquake

H. S. Virk, Vivek Walia and Anand K. Sharma

Department of Physics, Guru Nanak Dev University, Amritsar 143 005, India

Radon is recognized as a plausible precursor in earthquake prediction research. Radon monitoring in soil-gas and groundwater at Chamba and Dalhousie stations is carried out by using alpha-logger probes and emanometry. Radon anomalies are generally followed by seismic events in the grid (30–34°N, 74–78°E). The Chamba earthquake of 5.1 M, which occurred on 24 March 1995, had recorded its precursory signals.

Since the first observation of episodic changes in radon concentration in groundwater prior to the 1966 Tashkent earthquake[1], radon has been considered to be a plausible precursor for earthquake prediction. Observations of radon in soil-gas and groundwater have been recorded by various authors[2–10] and correlated with some of the earthquakes which occurred in USA, Japan, China, Mexico and India.

The physical basis of the radon anomalies prior to an impending earthquake have yet to be fully understood in terms of a comprehensive theoretical model. However, it is understood that the build-up of stresses prior to a seismic event induces strain fields in the crustal rocks; as a consequence, the radon emanation is enhanced. Model calculations indicate that a change in strain fields of at most 10^{-6}–10^{-8} caused the radon anomalies.

Radon monitoring work was started at Chamba and Dalhousie stations in Himachal Pradesh during March 1993 under the Himalayan Seismicity Programme of the Department of Science and Technology (DST), Government of India. Continuous radon monitoring is carried out in the soil-gas at Chamba and Dalhousie using the alpha-logger system, while radon is monitored daily at Dalhousie station in soil-gas and groundwater using the emanometry technique. The location of the monitoring stations is shown in the map (Figure 1), which shows major thrust faults in N–W Himalaya.

The alpha-logger probe (manufactured by Alpha-Nuclear Company in Toronto, Canada) is a portable battery-powered microprocessor-based data acquisition and control system. The detector probe consists of a silicon-diffused junction for the detection of alpha particles and can record radon alpha counts in 15 min increments over a period of 40 days non-stop. The detector unit is placed inside a covered auger hole about 60 cm in depth. The recorded data are retrieved with the aid of a laptop IBM-compatible PC by entering the proper commands. The software supplied with the system

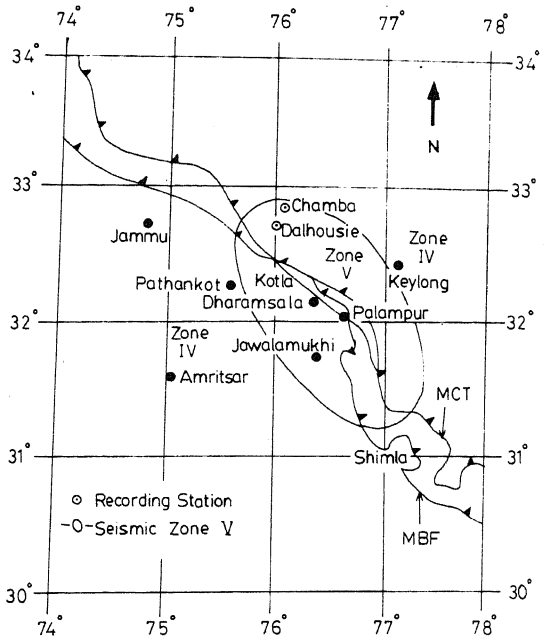

Figure 1. Map showing monitoring sites along with tectonic features in N–W Himalaya.

provides the facility to sum up any number of 15 min counting intervals for better counting statistics.

Radon monitoring in groundwater and soil-gas was carried out daily at Dalhousie station using the emanometry technique. The groundwater sample was collected from a 'bauli' (natural spring) at village Banikhet, 7 km from Dalhousie, in a sample bottle. A closed-circuit technique[11] was used to collect the gas that had passed through the water sample in the ZnS(Ag) detector cell as follows: The air was circulated in the closed circuit containing a hand-operated rubber pump, a water sample bottle, a drying chamber and a ZnS(Ag) detector cell for 10 min. Radon counts were recorded after 4 h, during which time the equilibrium between radon and its daughters gets established.

For measuring radon in soil-gas, auger-produced holes were left covered for 24 h, the same holes being used daily for radon monitoring. An emanometer was used to measure the alpha particle emission from radon in the gas fraction of a sample by pumping the soil-gas into a scintillation chamber using a closed-circuit technique. The alpha particles emitted from the decay of radon and its daughters impact the scintillator ZnS(Ag) creating an energy pulse in the form of photons. These photons were recorded by the scintillation assembly consisting of a photomultiplier tube and a scalar unit.

The Chamba and Dalhousie stations were set up as a part of radon network established in Himachal Pradesh to monitor the seismic activity of N–W Himalaya. Time series alpha-logger radon data for Dalhousie station are

plotted in Figure 2 for the period October 1993 to March 1995. The first radon anomaly was recorded on 26 October, with a radon value of 18,873 counts/day, 191% above the average value. This was followed by a seismic event of magnitude 1.3 M on 28 October within an epicentral distance of 21 km. Similarly, there were other radon anomalies followed by seismic events as shown by arrows in Figure 2 and listed in Table 1. This clearly shows that radon precursory signals are recorded prior to seismic events in N–W Himalaya.

Radon monitoring at Chamba started in July 1993. Time series radon data are plotted in Figure 3 with radon anomalies followed by seismic events (shown by arrows) as listed in Table 2. During March 1995, the radon emanation registered an average value of 4010 counts/day (Figure 4 *a*). On 13 March the radon peak occurred with radon high of 7600 counts/day. It started decreasing thereafter and fell below the average value after the Chamba earthquake of magnitude 5.1 M, which occurred on 24 March 1995 with its epicentre at Pliure, nearly 7 km away from Chamba town.

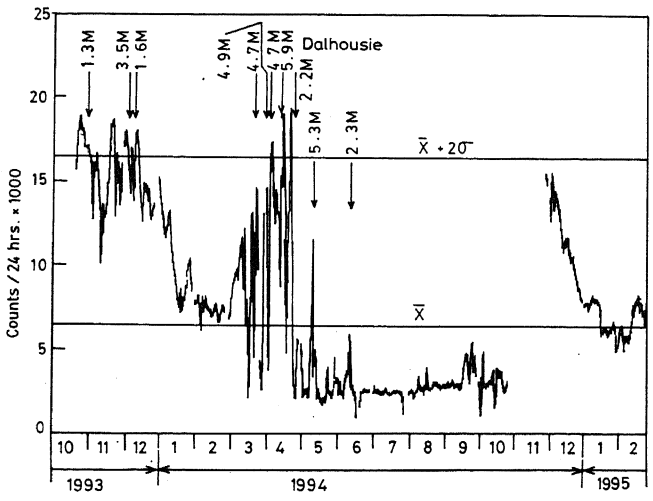

Figure 2. Time series alpha-logger data at the Dalhousie station.

Table 1. Correlation of radon anomalies at Dalhousie and the corresponding earthquake data

Date of radon anomaly	Date of the event	Magnitude	Alpha counts/day	Percentage increase above the mean value
26.10.93	28.10.93	1.3	18873	191
23.11.93	03.12.93	3.5	18625	187
02.12.93	05.12.93	1.6	18078	178
21.03.94	23.03.94	4.7	13166	103
24.03.94	30.03.94	4.9	14548	124
01.04.94	03.04.94	4.7	14575	124
06.04.94	09.04.94	5.9	17382	168
23.04,94	25.04,94	2.2	19343	198
10.05.94	10.05.94	5.3	11516	77
12.06.94	12.06.94	2.3	5846	–10

Radon monitoring at Dalhousie station shows some interesting trends (Figure 4 *b*): an enhancement till 16 March, then a fall, followed by a negative radon peak on 21 March, 3 days before the Chamba earthquake. Radon emanation showed a sudden rise after 21 March and this trend continued till 28 March; thereafter it started decreasing on 29 March. It reached its minimum value on 30 March after the seismic event of magnitude 3.0 M which occurred on 29 March. Chamba station became unoperational due to battery failure on 25 March and hence could not record the signal prior to 29 March event. The apparently different radon trends at both the stations may be explained on the basis of different geological conditions at the radon monitoring sites, their location from the main boundary fault (MBF) and the variation of the stress intensity factor[12].

Radon emanometry data (Figure 5) recorded the Chamba earthquake precursory signals more faithfully in both soil-gas and groundwater at Banikhet site near Dalhousie. The average radon values for March 1995 in soil-gas and groundwater were 71 and 98 counts/200 s, with a standard deviation of 97 and 103 counts, respectively. The radon anomaly was recorded simultaneously in both

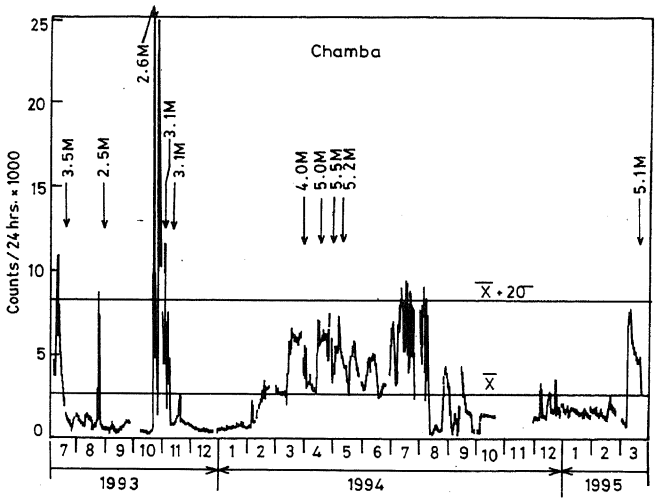

Figure 3. Time series alpha-logger radon data at the Chamba station.

Table 2. Correlation of the radon anomalies at Chamba and the corresponding earthquake data

Date of radon anomaly	Date of the event	Magnitude	Alpha counts/day	Percentage increase above the mean value
10.07.93	12.07.93	3.5	10906	309
26.08.93	28.08.93	2.5	8664	225
25.10.93	25.10.93	2.6	28837	982

30.04.94	01.05.94	6.5	7536	182
09.05.94	09.05.94	5.2	7355	176

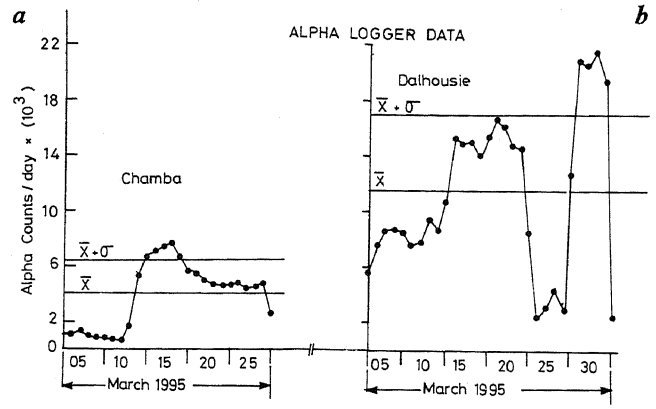

Figure 4. *a*, Alpha-logger radon data recorded at Chamba during March 1995. *b*, Alpha-logger radon data recorded at Dalhousie during March 1995.

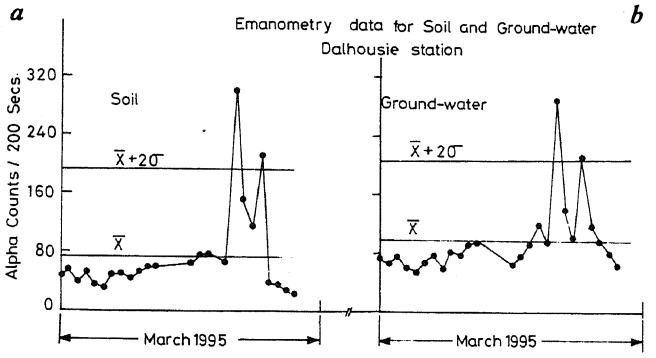

Figure 5. *a*, Radon emanometry data in soil-gas at Dalhousie during March 1995. *b*, Radon emanometry data in groundwater at Dalhousie during March 1995.

the media on 21 March, three days before the occurrence of Chamba earthquake and a day before a local event of magnitude 2.0 M, with peak values crossing the $x+2\sigma$ level. There was another peak on 24 March and then a sudden fall in the radon emanation rate after the strain was released. The simultaneous recording of radon peaks in both soil-gas and groundwater at the same site and under similar meteorological conditions before the occurrence of Chamba earthquake on 24 March establishes the efficacy of radon as an earthquake precursor. It also augurs well for setting up radon monitoring networks in N–W, Central and N–E Himalaya for the purpose of earthquake prediction studies and delineation of hidden faults.

Palaeogeographic evolution of the Akkulam lake and its geotechnical implications in the urban development of Thiruvananthapuram

K. Reghunadh, K. Sajan and S. Mohanakumar*

Marine Geology Division, School of Marine Sciences, Cochin University of Science & Technology, Cochin 682 016, India
*Govt. Engineering College, Thiruvananthapuram 695 081, India

The palaeogeographic evolution of the Akkulam lake and its geotechnical significance based on field observations, mapping, lithological core sampling and geotechnical laboratory studies are highlighted. The findings have important implications in the future urban development of Thiruvananthapuram.

FROM a geological perspective all lakes are temporary features in the terrestrial landscape. Lakes originate, evolve and ultimately disappear. They differ from one another mostly in terms of their mode of formation, course of evolution, duration of existence and their ultimate disappearance.

The present investigation is concerned with the palaeogeographic evolution of the Akkulam lake and its geotechnical implications in the future development of the fast-growing urban area of the city of Thiruvananthapuram.

The Akkulam lake is one of the minor lakes located within the coastal plain immediately north of Thiruvananthapuram. The lake presently covers an area of 1.7 km^2 and is intermittently connected with the Lakshadweep

sea through a tidal channel. A temporary transverse sand bar, generally 3 m wide and over 15 m long, cuts off the tidal channel from the sea, preventing direct contact with the latter during most of the year, except during periods of high rainfall. Thus, the lake forms a 'blind' estuary[1]. The manmade inland canal, the Parvathy Puthen Ar, enters this tidal channel. This canal continues further southwest into the coastal plain at a distance of 1.5 km from the coastline, almost parallel to the strandline. The two bridges, one connecting the coastal roads and the other connecting the railway tracks, are constructed across this tidal channel (Figure 1).

The study comprised the following methodology.

1. Geological and geomorphological mapping of the region in and around the Akkulam lake covering an area of 20 km^2 in the scale 1 : 20,000.
2. Drill core sampling, field study of sites of excavations, burrow pits, etc.
3. Lithological study of drill cores, materials of excavations (well cuttings, burrow pits and pits for foundations, etc.).
4. Geotechnical study of the lithological samples.
5. Preparation of a map showing zones of geotechnical hazards.

The field studies conducted in the region surrounding the basin of the lake have indicated that the lake was more extensive in the past, and an arm of the lake appears to have extended up to Kannanmoola for a distance of 6 km from its present margin (Figure 2).

The geomorphological features of the southeastern part of the study area adjoining the lake afford clear evidence of the shrinking of the lake basin to its present size. The landform is characterized by a flat, featureless terrain not exceeding 2.5 m above the water surface of the lake. This low-relief landform resembles that typical of flood plains of aggradation or of valley fills. Data from drill holes, pits and excavations collected from nine selected sites within the valley floors between Akkulam and Kannanmoola afford unmistakable evidence to show that it is genetically a valley flat of aggradational nature where presence of abnormal thickness of sediments has been shown to exist. The sediments forming the infilled portion within the area between the hill-side escarpments and slopes have an aggregate thickness ranging from 11 to 20 m. The width of this zone of aggradation is not uniform, with widths varying from 100 to 500 m. The total area occupied by the sediment infilled zone is estimated to be 11,80,000 m^2. Considerable thickness (ranging in aggregate thickness from 6 to 22 m) of plastic clays alternating with sediments of silty and sandy horizons occupies this tract (Table 1).

A narrow channel of 15 m width occupies the central portion of the sediment-infilled portion of the lake. While the net flow of water in this channel is seaward, the direction of flow is reversed once or twice daily according to the tidal regime. Tidal influence is experienced in this channel up to just north of Vempalavattom and perceptible effects are recorded during some months in this channel as far as Kannanmoola, when the sand bar of the estuarine mouth is breached. Marshy tracts and paddy fields occupy both sides of the sediment-filled portion of the Akkulam basin, extending laterally up to the terraced bluffs flanking the valley-side escarpments, where extensive coconut cultivation prevails. In the neighbourhood of Kannanmoola the sediment infilled part of the Akkulam basin supports extensive marshy tracts almost throughout the year, where enormous thickness of plastic clays highly enriched in organic matter is known to attain an aggregate thickness of over 20 m.

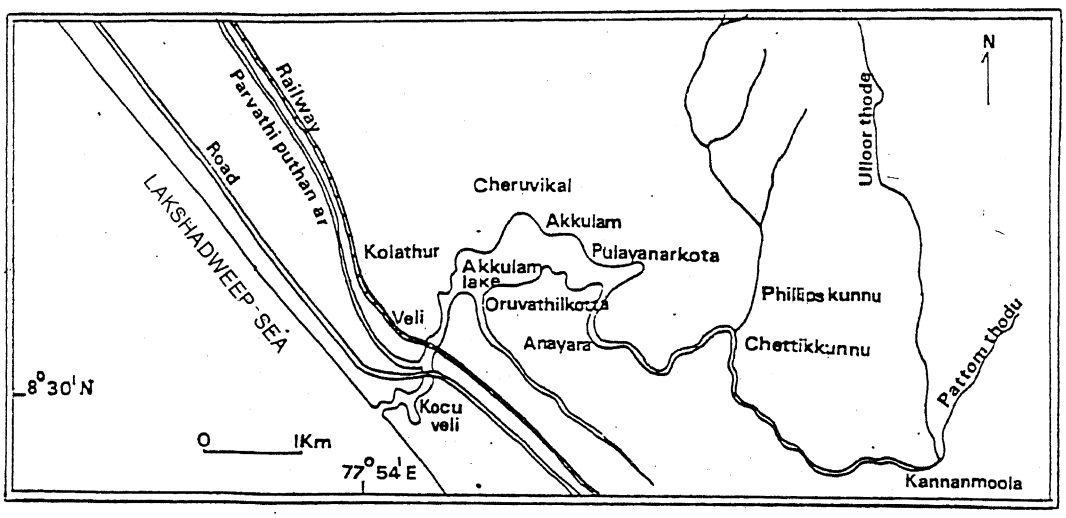

Figure 1. Geological map of the region around the Akkulam lake covering an area of 20 km^2.

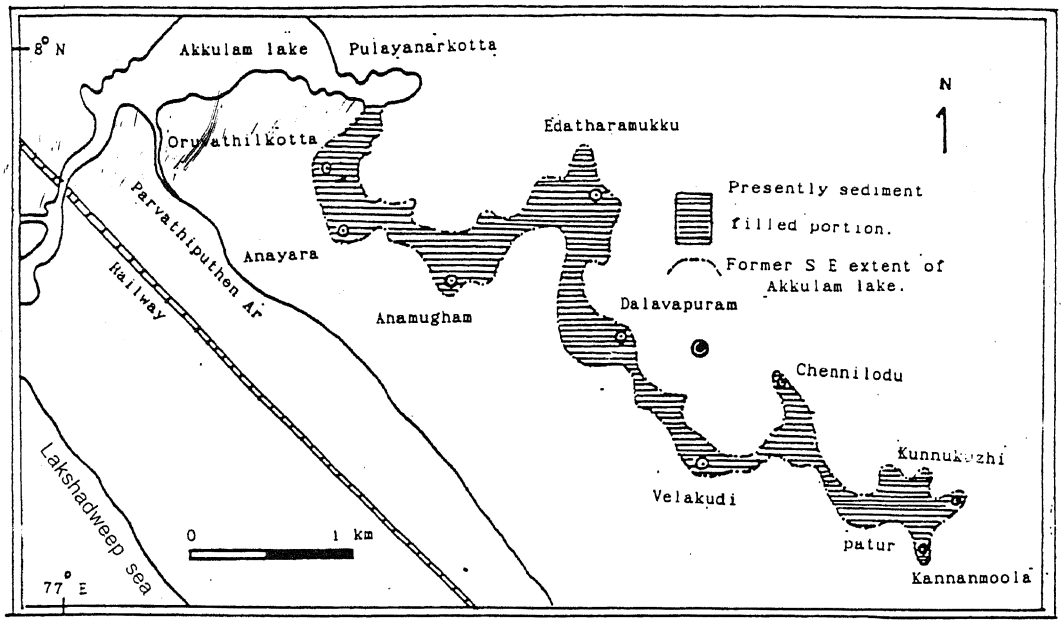

Figure 2. Geomorphological map of the region around the Akkulam lake covering an area of 20 km^2.

This locality is situated 5 km inland from the present coastline and occupies almost the central part of the city of Thiruvananthapuram.

The drill core samples collected from the sediment-filled portions of the Akkulam basin from Kannanmoola comprise occasional horizons containing skeletal fragments and complete shells of molluscs, and other invertebrates characteristic of brackish water environments. Thus, the palaeontological observations afford another strong evidence for the prevalence of brackish water condition up to Kannanmoola somewhere in the recent past.

Yet another evidence supporting the palaeogeographic change of the Akkulam lake basin is afforded by the drainage pattern of the existing fluvial system physically associated with the present lake basin. A number of stream systems extending over an aggregate area of about 30 km debouch their discharges into the Akkulam lake. Among these, the southerly flowing Ulloor Thode and southwesterly flowing Pattom Thode are the prominent ones. In addition, a few smaller streamlets enter the lake from its northern side traversing Kolathur, Cheruvickal and neighbouring localities. The Ulloor Thode and the Pattom Thode combine together at the centre of the marshy tract of Kannanmoola – the locality, as already noted, represents probably the former southeastern extremity of the present Akkulam lake. The sediment accumulation process in the portion of the lake basin from Kannanmoola up to Akkulam left only a narrow channel up to its present margin to drain away the discharges received from Ulloor Thode and Pattom Thode. A close study of the drainage pattern of the region reveals an abrupt northwestward diversion of the downstream portion of the stream channel beyond the point of confluence of Pattom Thode and Ulloor Thode. This unusual stream pattern indicates perhaps that in the past the streams had their termination near Kannanmoola up to where the southeast-trending arm of the Akkulam lake extended and subsequent infilling of this portion of the lake basin forced the stream channel to extend gradually up to Akkulam – the lake's present margin.

The urban area of Thiruvananthapuram is growing at an accelerated rate and the urban–suburban boundary is expanding at different rates along different directions. The scarcity of land for building construction has forced increasing reclamation of most of the paddy fields that occupied a substantial portion of the urban area. The building construction activity has already reached the infilled southeastern portion of the Akkulam basin. This tract being a geotechnically hazardous zone, special precautionary measures should be taken for foundation treatment while planning construction of buildings, especially high-rise constructions. Field studies have indicated serious damages of various sorts even in newly constructed buildings in this tract due to foundation problems. The enormous thickness of plastic clays in the sedimentary succession of this tract, extending up to Kannanmoola should be taken into consideration in planning future urban development of the infilled portion of the Akkulam basin.

The clay-enriched sedimentary succession has a significant influence upon its geotechnical properties. The moisture content and the energy with which this moisture

is held are the important factors to be taken into account while planning high-rise buildings in such areas, since these determine the consistency, strength and volume changes resulting from swelling, shrinkage and consolidation, which are also related to permeability and migration of moisture. Volume changes can occur as a result of loading consequent to consolidation and heave, due to reduction in void ratio. Because of their low permeability, the rate of consolidation will be a relatively slow process but the net effect will be considerable over a long span of time. The sensitivity of the clays of the region, i.e. the ratio of the undisturbed to the remoulded strength at the same moisture content ranges from about 3 to 6. Because of the high content of moisture of the clays, any fluctuation in the moisture content may increase the sensitivity of these clays. However, the ultimate bearing capacity of foundations on clay-enriched successions is influenced by its shear strength, which, in turn, depends on its consistency as well as the shape and depth at which the structure is placed. There are unmistakable evidences of severe foundation problems in the sediment-infilled portion of the Akkulam basin in the form of collapse of bridges due to tilting of foundations at localities such as Anamughom, near Edatharamukku and Nelliazhi. The shear strength of the clays determined for samples obtained from deep excavations and drill cores gave values ranging from 20–60 kN/m^2.

The study revealed that the Akkulam lake initially extended from its present margin up to Kannanmoola in southeast. Geomorphological, geological and palaeontological evidences support this view. This infilled arm of the lake contains considerable thickness of plastic clays and thus constitutes a geotechnically hazardous zone. This fact should be taken into consideration while planning major civil engineering constructions for the future urban development programmes.

Characterizing intergeneric regenerants of protoplast fusion between *Hyoscyamus muticus* (Egyptian henbane) and *Atropa belladonna* (Indian sagangur)

C. C. Giri and P. S. Ahuja*

Centre for Plant Molecular Biology, Department of Genetics, Osmania University, Hyderabad 500 007, India
*Plant Tissue Culture Division, Central Institute of Medicinal and Aromatic Plants, Lucknow 226 015, India

In the absence of a selection system, protoplast fusion between *Hyoscyamus muticus* L. and *Atropa belladonna* L. was obtained. The conditions for obtaining such a fusion were determined. The regenerants obtained subsequent to fusion were characterized based on morphology and cytological analysis. The regenerants exhibited phenotypes that were intermediate or resembling the parental types.

HYOSCYAMUS MUTICUS L. was introduced into India from Egypt for its cultivation and medicinal use[1]. Combining some characteristics of this species, viz. alkaloid content and arid habitat in a plant like *Atropa belladonna* (a sexually incompatible distant relative) is an essential step in the improvement of these medicinally important plants. Production of somatic hybrids was reported between sexually incompatible plant species specifically for obtaining higher content of secondary metabolites[2]. Besides somatic hybridization the improvement of plant bearing tropane group of alkaloids was reported through protoclonal variation[3]. Protoplast fusion between *A. belladonna* and *H. muticus* was attempted and the analysis of a few of the fusion products is reported in the present paper.

Seed materials of *A. belladonna* L. ($2n = 72$) and *H. muticus* L. ($2n = 28$) were obtained from CIMAP experimental farm. Callus cultures were established from leaf explants on MS[4] medium supplemented with α-naphthaleneacetic acid (NAA, 2 mg/l) and benzylaminopurine (BAP, 0.5 mg/l) from *in vitro* grown plants. Suspension cultures from both the plants were established using the same medium in liquid[5]. Protoplasts were isolated from 3-month-old suspension cultures. Parental protoplasts (1×10^6 protoplasts/ml of each parent) were mixed in a centrifuge tube, centrifuged for 5 min at $30 \times g$ and the supernatant removed. One ml of fusion solution containing 25% PEG (mol. wt. 3500), 9% mannitol, 2.36% $Ca(NO_3)_2 \cdot 4H_2O$ was added slowly along the wall of the centrifuge tube and then incubated for 0–10 min at 30–32°C. PEG was diluted out slowly with a high-pH Ca^{2+} solution (0.74% $CaCl_2 \cdot 2H_2O$, 0.375% glycine, 10% mannitol, pH 10.5). The duration of incubation in the fusogen or dilutant was varied to determine the optimum fusion frequency.

The protoplasts were then further diluted with a stabilizer solution (0.74% $CaCl_2 \cdot 2H_2O$, 0.75% glycine, 10% mannitol in CPW salts[6], pH 5.8) for at least 1 h. Finally, the settled protoplasts were washed with protoplast culture medium (PCM). Estimation of fusion frequency was done as per Kinsara *et al.*[7] using fluorescence labels FITC (fluorescein isothiocyanate), RITC (rhodamine isothiocyanate)[6], before culture of protoplasts.

After fusion, the heterokaryons along with the parental protoplasts were cultured at an optimum culture density (1×10^5 protoplasts/ml) in a standardized PCM (MS + 3% sucrose (w/v), 9% mannitol (w/v), 1 mg/l NAA, 0.2 mg/l 2,4-dichlorophenoxyacetic acid (2,4-D), 0.5 mg/l BAP)[5].

Chromosomal counts in the actively growing healthy root tips (1–2 mm) of plants regenerated *in vitro*, hybrid callus and parental seedlings were determined. The roots or calli were pretreated in a saturated solution of *p*-dichlorobenzene (PDB) for 4 h (initially for 5 min in a deep freezer and subsequently at 7°C). The tissue of *A. belladonna* was pretreated in water for 24 h at 2°C. All the tissues were fixed in 1 : 3 :: acetic acid : absolute alcohol. The samples were stained with a mixture (1 : 9) of 1 N HCl and 2% aceto-orceine (dissolved in 45% glacial acetic acid).

Protoplast fusion between *H. muticus* and *A. belladonna* was confirmed on the basis of differential staining by FITC and RITC. The frequency of fusion of protoplasts from *H. muticus* and *A. belladonna* is shown in Table 1. The frequency of the heterokaryon formation with PEG alone is low (0–0.9%). Heterokaryon formation was 2.6% when the parental protoplasts were incubated in high Ca^{2+}/high pH solution for 20 min. However, this frequency could be marginally increased to 3.0% if the parental protoplasts were incubated in PEG for 5 min earlier. Also bursting of protoplasts was noticed to be lower in this treatment than with PEG alone. Thereafter,

Table 1. The effect of the interaction of PEG and ionic solution (high pH/Ca^{2+}) on heterokaryon formation* between protoplasts of *A. belladonna* labelled with FITC and *H. muticus* labelled with RITC

A minimum of 25 microscopic fields were observed to arrive at the fusion frequency.

incubating the protoplasts for further time periods in either of the solutions did not increase the fusion frequency. Plating efficiency of parental protoplasts was to the tune of $56 \pm 2\%$ and $47 \pm 1.5\%$ in case of *H. muticus* and *A. belladonna*, respectively. However, when protoplasts were cultured after fusion at same culture density as parents (1×10^5 protoplasts/ml), the plating efficiency was observed to be $68 \pm 2\%$. Fast-growing colonies were visible within 4–5 weeks of culture. From 50 fast-growing colonies 15 callus lines were obtained. These callus lines were then transferred to a semisolid agar (0.8%) MS regeneration medium containing 3% sucrose 0.1 mg/l NAA and 0.5 mg/l BAP. Regenerated shoots developed into complete plantlets when the shoots were transferred to rooting medium containing half-strength MS nutrients without phytohormones. The regenerated plants were selected visually on the basis of the morphology, pattern and plant regeneration frequency. Calli obtained after fusion were highly compact and green compared to parental calli, which were fragile and yellowish green in nature. There was significant difference in the regeneration potential of hybrid callus compared to parental protoplast callus. The regeneration frequency from protoplast-derived calli of *H. muticus* and *A. belladonna* protoplasts was 80% and 60%, respectively. However, the regeneration frequency of callus obtained after fusion was extremely high (100%), i.e. whole of the callus would transform into regenerants. Similar screening for somatic fusion product was reported in other plant species where no selection system was available[8–11].

Amongst the different callus lines studied, plants regenerated from four selected calli were peculiar as some regenerants showed intermediate phenotype (Figure 1). From four such callus lines, 15 plants showing intermediate phenotypes were obtained and 9 of these plants were transferred to glasshouse. These plants flowered within 9–10 weeks of transfer to soil. The flower morphology in such plants was different from the parental types. The flowers had larger petal

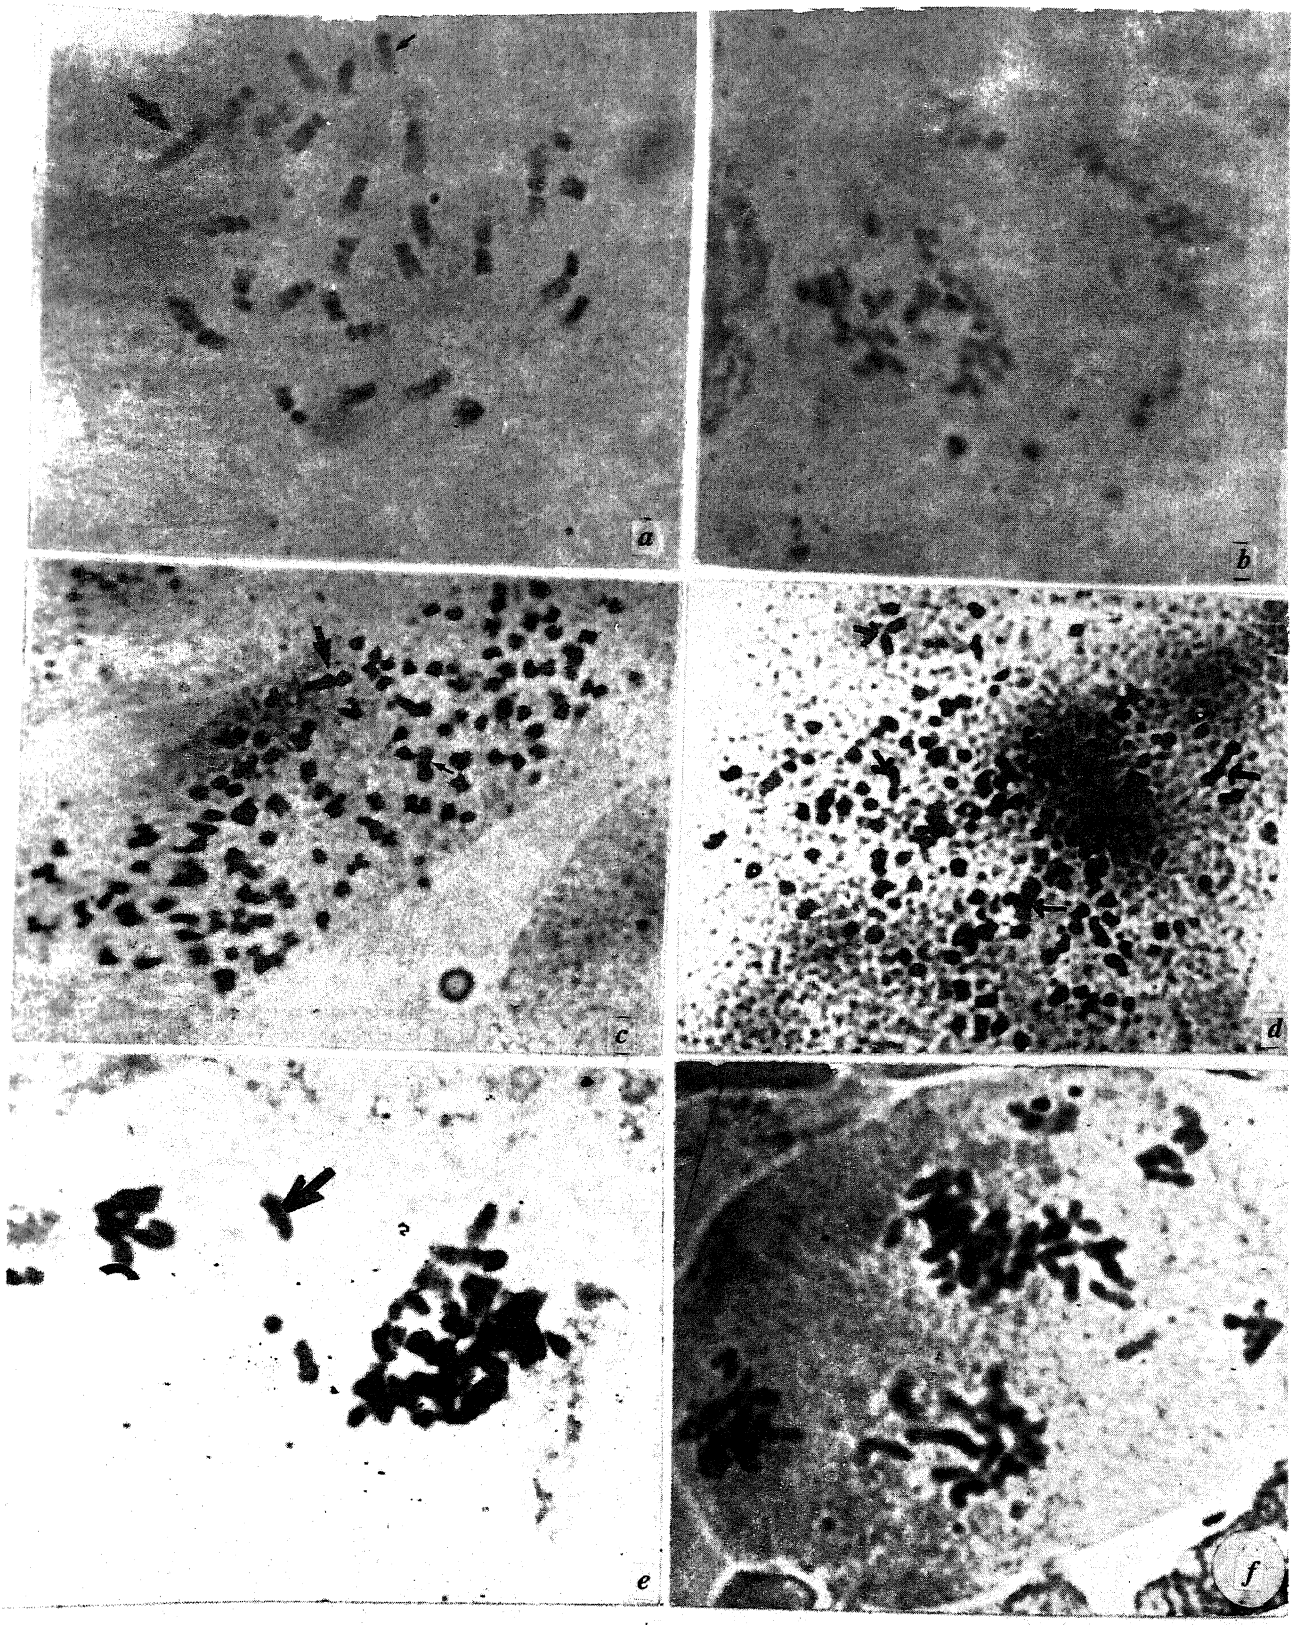

Figure 2. Somatic chromosome analysis of the parents and putative asymmetric hybrids between *H. muticus* and *A. belladonna*. *a,b*, Metaphase chromosome of *H. muticus* ($2n = 28$) and *A. belladonna* ($2n = 72$). *c,d*, Chromosomes of fusion-derived regenerated plants ($2n = 100, 109$), majority of chromosomes are smaller *belladonna* type with few *muticus* type (arrow). *e*, Unequal anaphase separation (disjunction) with laggard chromosome (arrow). *f*, Multipolarity of chromosome during anaphase separation.

size compared to parents. They also differ in number of petals (6) and stamens (6) compared to parents (5). The shape and colour of anther was changed to heart-shaped white compared to rod-shaped purple in the parents.

These four selected callus lines in subsequent culture passage gave rise to two types of regenerants resembling *H. muticus* and *A. belladonna*. The regenerants included 12 asymmetric hybrids resembling *A. belladonna* and 17 resembling *H. muticus*. In a similar finding both *Arabiodopsis* and *Brassica* plants were found to regenerate from the same hybrid callus during the culture passage[12].

Table 2 shows mitotic chromosome analysis of selected calli and regenerated shoots showing intermediate phenotype (symmetric hybrids) or resembling the parental types (asymmetric hybrids). In the hybrid callus the chromosome number ranged from 83 to 140. Few regenerants which possessed intermediate phenotype showed chromosome numbers between 100 and 108. Of the asymmetric hybrid plants, those resembling *A. belladonna* possessed 56 to 100 chromosomes and those resembling *H. muticus* was 24–56. The cytological analysis of the chromosomes for the plants resembling *A. belladonna* showed a few larger-sized chromosomes of *H. muticus* (Figure 2 *c*, *d*). The *H. muticus* type of regenerants showed the presence of smaller-sized chromosomes of *A. belladonna*. This could have resulted in the production of asymmetric hybrids. Cytological anomalies such as elimination of chromosomes, unequal separation of chromosomes with the presence of laggards and multipolar orientation of chromosomes during anaphase were observed when the calli were observed after several subcultures (Figure 2 *e*, *f*).

The chromosome elimination subsequent to somatic hybridization was found to occur in most of the fusion studies. Chromosome elimination was observed in fusion involving *Arabiodopsis thaliana* and *Brassica campestris*[13]. In a study on the fusion between *A. belladonna* and *N. chinensis* the elimination of parental chromosomes has been observed. In most of the cases species-specific elimination takes place[14–16]. Similar findings were also obtained in studies on somatic hybridization between *A. belladonna* and *Datura innoxia*[17]. The phenomenon of chromosome elimination in the present study can be exploited for raising asymmetric hybrids and may be used for limited gene transfer as has been reported earlier with other crops[18]. The present work indicates the possibility of producing an intergeneric somatic hybrid between two medicinally important plants in the absence of a selection system.

Mechanism of wound healing induced by chitosan in streptozotocin diabetic rats

A. Naseema, Pius S. Padayatti and C. S. Paulose

Molecular Neurobiology and Cell Biology Unit, Centre for Biotechnology, Cochin University of Science & Technology, Cochin 682 022, India

Diabetes mellitus is a common metabolic disorder associated with many pathological conditions. Prolonged or incomplete wound healing is one among them. This is due to poor blood circulation, alterations in circulating constituents, abnormal platelet aggregation and decreased fibrinolytic activity. The aim of the present study was to envisage the role of chitosan in wound healing and to investigate its effect in normalizing the aggregation pattern of platelets in diabetes. At very low concentrations, chitosan has no effect on platelet aggregation, while high concentrations can aggregate the platelets. Chitosan is not capable of reversing the increased rate of aggregation in diabetic platelets. The number of platelets which may affect the normal clotting process were also significantly lower in diabetic rats. Chitosan was found to be a good wound-healing agent, even though it does not reverse the altered platelet aggregation. Chitosan may be enhancing wound healing by some other mechanism independent of its effect on platelet aggregation.

DIABETES mellitus is caused by decreased secretion of insulin by the β cells of Islets of Langerhans, lack of

glucose-metabolizing enzymes and gluconeogenesis from noncarbohydrate sources. This disease is associated with many pathological conditions. Prolonged or incomplete wound healing is one among them. This is due to poor blood circulation, alterations in circulating constituents, abnormal platelet aggregation and decreased fibrinolytic activity. Platelet aggregation is of primary importance in normal haemostasis. When a blood vessel is cut, a platelet plug is formed by the process of platelet aggregation[1]. So any change in platelet function or in platelet number can finally lead to a difference in the blood-clotting process, which, in turn, causes prolonged wound healing[2]. Poor blood circulation makes diabetics prone to infection of the foot, commonly called diabetic gangrene.

In some recent studies, agonists like ADP, hydrogen peroxide, thrombin, etc., were used to understand the process of platelet aggregation. Many workers reported the effect of chitosan as an enhancer in wound healing. Chitosan in solution coagulates red cell membranes. It is this property of chitosan which finds wide applications in the field of neurosurgery and wound healing[3].

In the present study our aim is to envisage the role of chitosan in wound healing in diabetes and to investigate the effect of chitosan in normalizing the altered platelet aggregation in diabetes mellitus.

Animals used were Sprague Dawley strains of rats with ~ 200 gm body weight. They were maintained on gram (*Cicer arietinum*) and tap water supplied *ad libitum*.

For wound-healing studies, female rats were used. They were divided into group I (control rats), group II (control rats with chitosan powder applied to artificial wounds), group III (diabetic rats), group IV (diabetic rats with chitosan powder applied to artificial wounds).

Animals used for platelet aggregation studies were classified into group I (control animals) and group II (diabetic animals).

Diabetes was induced using streptozotocin (STZ)[4]. Body weight and blood glucose levels were measured throughout the experimental period. Glucose level from tail vein blood was estimated with GOD-PAP method by using a glucose kit (Merck).

In order to examine the process of wound healing, two artificial wounds, one on the back of the neck and the other on the leg, were made in the above four groups of animals by removing the cutis and subcutis (2–3 cm long). Then these artificial wounds in group II and group IV animals were treated with chitosan powder and the other two groups were left as such. Wound healing was assessed visually.

Platelets were prepared by collecting blood from tail vein of control and diabetic rats using the method of Domino *et al.*[5]. Platelets were counted using haemocytometer under phase contrast microscope[6]. Platelet aggregation was assayed using the method of Jamaluddin and Krishnan[7]. The PRP was diluted to make it 7×10^7 cells/ml of the experimental solution. The agonist used was 1 mg/ml chitosan solution. The agonist concentration used varied from 15 to 60 µg.

For finding out the initial rate of platelet aggregation, the number of single platelets was counted by withdrawing the sample at zero time and at various intervals after adding the agonist from a cuvette kept outside the spectrophotometer and counted immediately for finding out the percentage of single platelets[6].

Streptozotocin administration caused an elevation in the blood glucose level, decrease in body weight and increase in water uptake in all experimental animals (group II) (Table 1).

At very low concentrations of the agonist (3–15 µg/ml), the turbidity was found to increase as a function of time up to a particular point, which then stabilized in both control and diabetic samples (Figure 1).

At high concentrations of chitosan (50–60 µg/ml), the turbidity increased first and then decreased rapidly and stabilized. The normal agonist epinephrine also showed the same pattern of aggregation (data not shown). In diabetic samples the aggregation started within 10 s,

Table 1. General characteristics of experimental rats

	Blood glucose level (mg/dl)	Body weight (g)	Water uptake (ml)
Control	96.4 ± 3.0	170.0 ± 3.5	17.7 ± 1.1
Diabetic	256.9 ± 26.0*	147.5 ± 7.3*	61.0 ± 6.7*

Values are mean ± SEM of 5–6 separate experiments.
*$P < 0.05$ compared to control.

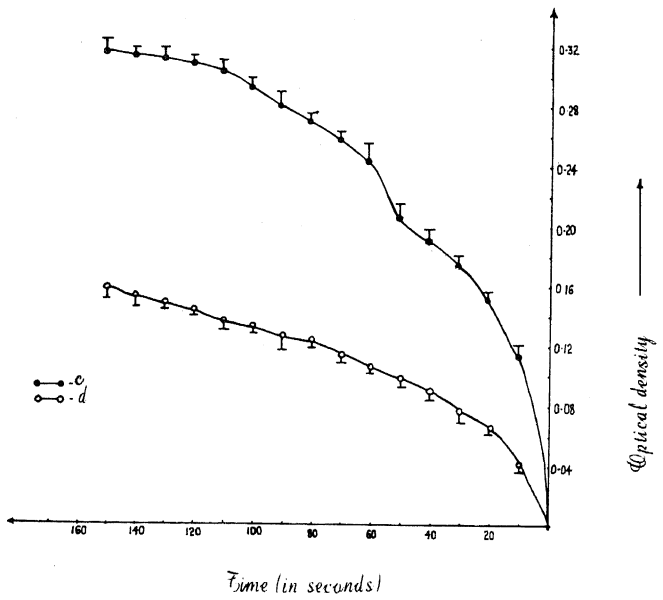

Figure 1. Platelet aggregation pattern induced by low concentrations of chitosan in control (●) and diabetic (O) rat platelet-rich plasma. Values are mean ± SEM of 4–6 separate experiments.

while in control it started within 20 s (Figure 2). The decrease in turbidity was associated with a decrease in the percentage of single platelets. The initial rate of aggregation (r_0) obtained showed significant increase ($P < 0.05$) in diabetic samples compared to controls (Figure 3).

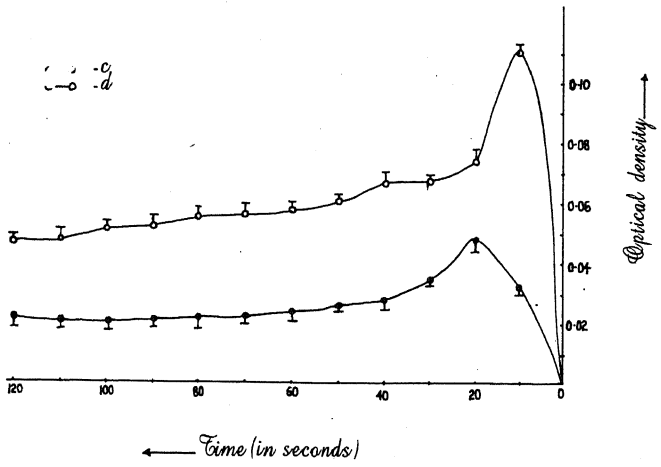

Figure 2. Platelet aggregation pattern induced by high concentrations of chitosan in control (●) and diabetic (O) rat platelet-rich plasma. Values are mean ± SEM of 4–6 separate experiments.

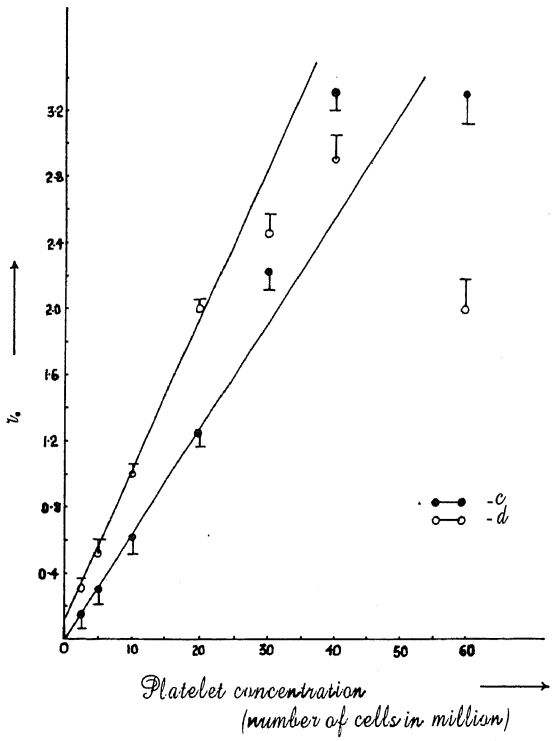

Figure 3. Changes in spectrophotometrically determined initial rates (r_0) of chitosan-induced aggregation of control (●) and diabetic (O) rat platelet-rich plasma as function of platelet concentration. The lines were drawn to show deviation of data from linearity. r_0 was calculated from the graph of percentage of single platelet (on Y axis) against time (on X axis). The slope of the graph is expressed as r_0.

The number of platelets in diabetic rats was significantly less ($P < 0.05$) compared to control rats (Table 2).

Visual observation of chitosan applied on artificial wounds in experimental animals showed considerable difference in wound-healing capability compared to controls without chitosan treatment. The chitosan-applied wounds in diabetic and control rats healed much earlier than the wounds without chitosan treatment (Table 3).

The significant elevation of blood glucose level, decrease in body weight and increase in water uptake in STZ-induced diabetes mellitus is due to altered carbohydrate metabolism brought about by selective destruction of Islet β cells by the toxin[8].

From our findings it was observed that very low concentrations of chitosan did not enhance platelet aggregation. From their study Olsen *et al.*[3] reported the mechanism by which chitosan induces gel formation with RBC, shown to be due to interaction of the positively charged chitosan polymers with receptors containing neuraminic acid residues on the cell membrane. The mechanism behind the interaction between platelets and chitosan may be in the same pattern. At very low concentrations there may be inadequate binding sites for chitosan. This may be the reason why low concentrations of chitosan did not enhance platelet aggregation.

We observed enhanced platelet aggregation with high concentrations of chitosan. The optical density, which

is a direct measure of turbidity, increased first and then decreased. Many workers have reported the pattern of ADP-induced platelet aggregation[9]. The pattern of chitosan-induced aggregation resembles the ADP-induced pattern. Thus, chitosan can act as a normal agonist like ADP. The initial increase in optical density was reported to be due to shape change of platelets[10].

In the present study we observed increased platelet aggregation in diabetic condition. This can be explained by the findings of many workers. In 1972, Kwaan *et al.*[11] found out that there is significant increase in ADP-induced platelet aggregation in diabetic samples compared to controls. Aggregation in washed platelets from rats with diabetes was enhanced; this results in prolongation of thrombogenesis[12]. Platelet aggregation in response to ADP in washed platelets was increased in diabetic animals compared to controls. This is due to increased platelet size in diabetic animals[13]. *In vitro* platelet hyperaggregation was found induced with epinephrine in diabetic condition[14].

The observed significant decrease in the number of platelets in diabetic rats can be explained as follows. Zucker explains in his study that in severe atherosclerosis and in diseases such as thrombosis and diabetes, in addition to the growth factor, two other substances, platelet factor-4 and β thromboglobulin are released in large amounts, resulting in their rapid depletion from the circulation[15]. So the observed decrease in platelet number in both sexes of animals during diabetes may be related to altered secretory function of platelets. The decreased platelet number directly affects the platelet plug formation, which is an essential step involved in blood clotting. But from a visual observation we found that chitosan enhances wound healing in diabetic condition. Our result also showed that chitosan cannot normalize platelet aggregation in diabetic conditions. These two results point out that there is no relation between chitosan-induced platelet aggregation and wound healing. Biagini *et al.*[16]. reported that in patients undergoing plastic surgery, the donor sites were treated with *N*-carboxybutyl chitosan, which enhanced wound healing. This *N*-carboxybutyl chitosan leads to formation of regularly organized cutaneous tissue and reduces anomalous healing. Although chitosan was not found to help in normalizing the altered platelet aggregation, it helps in wound healing. Thus, chitosan-induced enhanced wound healing in diabetes observed in the present study may be due to organization of newly formed tissue and thus help in damage repair.

In conclusion this study presents the effect of the bioactive polymer chitosan in wound healing in diabetes mellitus.

Permeability of cuticle of *Helicoverpa armigera* (Hübner) larvae to deltamethrin

A. P. Padma Kumari, A. Phokela and K. N. Mehrotra

Division of Entomology, Indian Agricultural Research Institute, New Delhi 110 012, India

Permeability of the cuticle of *H. armigera* larvae to deltamethrin has been studied in three populations originating from Delhi, Sirsa and ICRISAT. Delayed penetration of topically applied ^{14}C-deltamethrin was observed in the Sirsa population. This suggests that the permeability of the cuticle plays an important role in imparting resistance in the Sirsa population, whereas in Delhi and ICRISAT populations it is not very important.

REDUCED permeability of the cuticle may be a factor conferring resistance in insect pests to insecticides[1-6]. *Helicoverpa armigera* (Hübner) has acquired resistance to synthetic pyrethroids (SPs) in major parts of India[7-10]. Recently, by a very indirect method some evidence was presented to suggest that the cuticle may, perhaps, play some role in manifestation of resistance to SPs in *H.*

armigera populations of Australia[11]. This led us to reinvestigate the permeability of cuticle to *H. armigera* larvae obtained from three widely separated areas, Sirsa (Haryana), Delhi, and ICRISAT, Andhra Pradesh. We report here that the reduced permeability of the cuticle plays a significant role in imparting resistance to *H. armigera* populations originating from Sirsa.

Final instar larvae of *H. armigera* used in the present study were collected from chickpea fields in Delhi, from cotton fields in Sirsa (village Balasar) on cotton and from weeds at ICRISAT. The Sirsa population had been subjected to local practices of plant protection prevalent in that area. But all the populations were conditioned on artificial diet[10]. For studying permeability, 0.1 µg ^{14}C-deltamethrin, about 80,000 Bq in one microlitre of methanol, was applied on the thoracic dorsum of the final instar larvae (weighing 350–375 mg), using an electrically operated microapplicator. Larvae treated for different time intervals were held in scintillation counting vials without any food. At intervals of 10 min, three larvae were washed individually with 5 ml of the scintillation mixture (0.55% w/v 2,5-diphenyl oxazole in 2 : 1 toluene and methyl cellosolve). These washings, having the remaining deltamethrin on cuticle, were estimated in a liquid scintillation counter[12]. The percentage of the remaining activity on the thoracic dorsum when plotted (on log scale) against time gave a straight line, suggesting that deltamethrin followed a first-order kinetics in permeating the cuticle. The $t_{0.5}$ value was computed for all the three populations.

The permeability of cuticles in Delhi and ICRISAT populations did not differ and was almost the same as that observed earlier[10]. However, the permeability was significantly different in populations originating from Sirsa. The computed $t_{0.5}$ value was 42.00 min for the Delhi population and 39.96 min for the ICRISAT population. In contrast to this, $t_{0.5}$ was 71.91 min for the Sirsa population (Table 1). This indicated that ^{14}C-deltamethrin had taken almost twice the time to penetrate the cuticle of the Sirsa population than the other two. The permeability of the cuticle of all the three populations was observed to be monophasic and followed first-order kinetics (Figure 1), which was similar to that reported earlier for insect cuticle and animal integuments[13–15]. It may also be mentioned that in a set of experiments on

Table 1. Permeability of the cuticle of final instar larvae of *H. armigera*

Location	$t_{0.5}$ (min)	Regression equation	r^2
Delhi	42.00	$Y = 2.0 - 0.00716x$	0.9445
ICRISAT	39.96	$Y = 2.0 - 0.00754x$	0.6789
Sirsa	71.91	$Y = 2.0 - 0.00419x$	0.9456

Note: $t_{0.5}$ is the time required for penetration of 50% of the applied dose. All values were significant at 5% level.

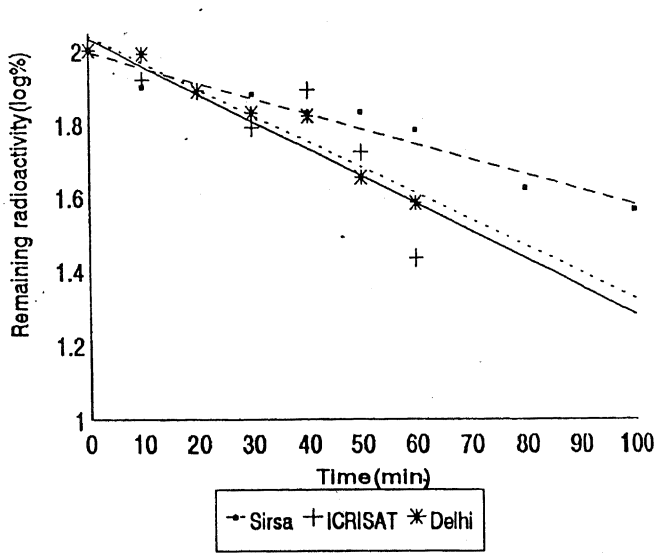

Figure 1. Permeability of *H. armigera* larval cuticle to ^{14}C-deltamethrin.

the metabolism of ^{14}C-deltamethrin it was found that metabolism was high in the microsomal fraction of cuticular homogenates of the Sirsa population than in the same of the Delhi population, the ratio being about 2 : 1 between Sirsa and Delhi. These results, therefore, suggest that poor permeability of deltamethrin along with high rate of metabolism in the cuticle itself was important in imparting resistance to the Sirsa population. It is likely that *H. armigera* populations have developed resistance to SPs by different mechanisms in different geographical/agro-ecological zones of the country. It is also possible that in the Sirsa population the cuticle is an important factor contributing towards resistance. Thus, the present studies suggest that 'PEN' mechanism, as suggested by Gunning *et al.*[16] in Australian strains, may play a prominent role in imparting resistance to SPs in the Sirsa population.

The 'basic' vs the 'evolved'

Quark and Jaguar. M. Gel-Mann. Little Brown and Co., London. 1994. 392 pp. Price: £ 18.99.

That Murray Gell-Mann's latest book gives the pride of place to the quark as the most basic building block of matter will presumably not be contested by its less dramatic partner, the lepton, since it must be 'aware' of the 'creator', in company with another genius[1], of this bizarre yet most concrete of all objects, especially after the announcement of the last and most elusive member[2] of the series. However, the corresponding privilege for the jaguar to qualify as a prototype for the most complex adaptive system on earth is more a matter of personal taste. (The choice could well have fallen on, say, the giraffe[3] if it were a different author). In any case one cannot but feel a sense of admiration for the poet (Arthur Sze) who had both the words (the quark and the jaguar) in his poetic dictionary and thus captured the literary fancy of the great physicist. This is somewhat reminiscent of an earlier occasion (three decades ago) when James Joyce, through his *Finnegans Wake*[4], had (inadvertently?) supplied the 'name' of the first member of this book.

While the title of a book is largely the prerogative of the author, the more relevant issue is the subject matter and the language in which it is intended to be conveyed. The general tone and the tenor of the book seems to be in keeping with the trend set by some of the author's distinguished contemporaries (Feynman and Dyson) to write personal glimpses on physics in an 'autobiographical' style, but since the author himself disclaims any autobiographical intentions, one must look for other, say educational, motivations designed to convey to the lay reader the significance of major discoveries in a frontline field in a sufficiently nontechnical language without too much sacrifice of rigour. Even such ventures are no longer considered novel, since after the debut of the *Tao of Physics*[5] nearly two decades ago, many impressive literary pieces dealing with abstract concepts in physical and mathematical sciences in a nontechnical manner by professional scientists of great distinction have appeared on the scene[6,7]. And now Gell-Mann has joined this select club with his own 'coup de grace'. In view of the great stature of the author, this book is bound to attract a good deal of attention, as well as an *inter-se* comparison with some of the classics[6,7] on cosmology on the one hand and other equally authoritative treatises[8] on a major aspect (chaos) of its theme on the other. Without presuming to pass a hasty judgement on the book, the issue of immediate concern is its 'thrust', together with the nature of the emphasis that the book wishes to convey.

What is the main thrust of the book? Fortunately, the distinguished author has himself provided enough summary on his own (at both ends of the book) to obviate any need on the reader's part to make an independent inference in this regard. The book is written in an intensely personal style and is studded with examples taken from the author's own experiences from family and friends alike. The entire setting is centred around the Santa Fe Institute (SFI) of Interdisciplinary Studies, which the author founded about a decade ago (after taking an early retirement from his home institution – Caltech) and which now represents his principal scientific base. Shorn of such personal details, the book is presented in four parts, in an obvious attempt to address a whole gamut of information, from 'the simple: a quark inside an atom' to 'the complex: a jaguar prowling its jungle territory in the night', together with the innumerable interrelationships among the various components that make up the whole and are continually showing dynamical manifestations in an ever-growing evolutionary scenario.

The first part of the book is an attempt to describe the relationships between the concepts of simplicity and complexity, especially of *complex adaptive systems* (CAS) – child learning a language, bacteria developing resistance against antibiotics, human scientific enterprise, and so on. The role of theory in science is discussed, 'as well as the issue of which sciences are more fundamental than others', along with the related question of reductionism. The second part deals with the fundamental laws of physics, those governing the cosmos and the elementary particles, out of which all matter in the universe is composed. Here the quark comes into its own (as does its creator); so do superstrings, which the author believes 'for the first time in history' to 'offer the serious possibility of a unified theory of all particles and forces of nature'. The third part is devoted to the various selection pressures operating in complex adaptive systems, 'especially in biological evolution, human creative thinking, critical and superstitious thinking' (which he strongly condemns), and some aspects (including economic ones) of the behaviour of human societies. Many *ad hoc* concepts, such as fitness and fitness landscapes are introduced along the way. The fourth and final part is concerned with policy matters (not science) and 'with advocacy'. (This reviewer hopes that the last phrase does not imply that the author considers science to be so objective as to be above policy and advocacy, since science does seem often to exhibit a high degree of subjectivity at the *operational* level)[9,10].

Now to some essential details concerning the different parts of the book. The most serious discussion (understandably) concerns the *second* part, which bears the characteristic imprint of the author's seminal contributions to elementary particle physics during the fifties and sixties (including the quark proposal among other things), as well as some fresh 'hard physics' on the foundations of quantum mechanics (carried out at his SFI). Since this topic dealing with the deeper issues of 'measurement' and 'paradoxes' is relatively new and still confined to the pages of technical journals, its wider appeal to the scientific community at large warrants some elaboration in this review (see below). However, the other, more familiar topics of the second part, as well as some from the first part, are treated rather briefly (within the limited space available), while Parts 3 and 4 are too 'righteous' (and personalized) for a cogent review.

Complex adaptive systems

Much of the discussion in Part 1 is taken up with a discursive analysis of complex adaptive systems (CAS), their patterns of evolution by acquiring information about their respective environments through their own interactions with the latter, identifying regularities in the information, condensing the (abstracted) regularities into a kind of schema or model, and acting in the real world on the basis of

that schema. Their capacity to learn from experience is itself a product of biological evolution, which in turn gives rise to other new types of CAS (e.g. immune system in mammals). Indeed, a CAS generally has a tendency to generate other such systems in turn. They are, of course, subject to the laws of nature, which themselves rest on the fundamental physical laws of matter and the universe. And (over and above the quantum-mechanical (q.m.) effects) indeterminacies arise, even in classical motion, partly due to an *approximate* knowledge of the initial conditions and partly due to *measurement imperfections*. The latter give rise to CHAOS[8], which tends to amplify the resultant indeterminacies (whether from q.m. effects and/or from measurement imperfections) to macroscopic levels. The entire discussion is studded with a rich vocabulary of terms with subtle distinctions in their meaning, depending upon the context of their use. Different types of complexity, along with several associated concepts (conciseness, crudity, algorithmic information content, information, compression, randomness, effective complexity, direct adaption vs CAS) abound in the text.

In Gell-Mann's view, the concept of CAS is well illustrated by the human scientific enterprise. The schemata are theories, and what takes place in the real world is the confrontation between theory and observations. This is strongly reminiscent of Holton's[11] definition of themata along with the associated concept of the contingent plane, which Holton had developed very systematically in the early seventies. (A summary of the main ideas involved may be found in ref. 10). In this regard Gell-Mann strongly endorses the dictum of philosopher Karl Popper concerning the falsifiability (by experimentation) of scientific theories. His views on the scientific enterprise as a self-correcting process (despite occasional abuses) as well as his endorsement of the themes of simplicity and unification in physical theories are quite standard, but his joining the issue, on grounds of semantics, with a distinguished contemporary thinker, Thomas Kuhn on his seminal theme of paradigm shifts[9] does not seem to carry the same degree of conviction.

Gell-Mann goes into great lengths in analysing the powers of theory at successively deeper levels of operation, stressing in the process its unifying role in bringing together apparently unrelated phenomena under a more transparent pattern which reveals their relationships, thus facilitating a more 'compressed' (compact?) description. He illustrates the idea with the simple example of how a relatively empirical model like Zipf's law has eventually evolved in the hands of deep thinkers (like Mandelbrot) into something quite profound: fractal behaviour and scale independence. (One may add in parentheses that it already has the germs of renormalization group theory). In this context he introduces several related terms like depth and crypticity as a sort of figure of merit for theorizing.

The quantum universe

Coming to the fundamental laws of matter and the universe, the distinguished physicist is at last on his own territory where he has every reason to look back with satisfaction at the culmination of his quark proposal[1,4] into the standard model of today. For good reasons he does not obviously believe in the finality of the so-called grand unified theories. He also does not have good words to say about Einstein's mental faculties during his twilight years of research on a unified field theory, pointing out several specific flaws in his approach due to the neglect of fields (weak and strong) other than the gravitational and electromagnetic as well as fermion fields, and, most importantly, the need to construct a unified theory within the framework of quantum mechanics. On the other hand, he seems to believe that Einstein's dream may at last have been realized with the superstring theory, which in his view has the right ingredients to accomplish the unification, since it predicts in a natural way the existence of the graviton within its broad framework. In particular, the heterotic superstring theory, which realizes this crucial quantum in a (conceptually) convincing fashion seems to fit the bill quite well without running into the perennial problems of infinities. Reasons? (i) It explains the great multiplicity of particles discovered and yet to be discovered in the laboratory. (ii) It does not contain any arbitrary particles or forces. (iii) It emerges from a simple and beautiful principle of self-consistency (which dates back to the bootstrap idea of the sixties just preceding the quark model).

Even if the superstring turns out to be eventually 'correct', its claims to TOE (theory of everything) is still beset with other problems. For, the actual evolution of the universe depends not only on the physical laws but also on the initial conditions plus the unknown effects of quantum fluctuations, which in turn are closely linked with the 'arrow of time' (On this topic, a nontechnical yet highly readable description may be found in ref. 6). Regarding the initial conditions, Gell-Mann recognizes that a good candidate is one already suggested by the Hawking–Hartle theory[6], viz. the no-boundary condition, which, along with the (weak) anthropic principle, is apparently able to account for the arrow of time[6]. On the other hand, Gell-Mann himself believes that since the laws of physics are quantum-mechanical (not deterministic) and permit only the calculation of probabilities of various alternative histories of the universe that describe different ways events could play themselves out (given the initial conditions), information about which of those sequences of events is actually occurring can be gathered only from observation and is supplementary to the basic laws themselves. And further, each alternative history of the universe depends on the results of an inconceivably large number of accidents. The chance outcomes of the latter (*á la* quantum mechanics) have 'determined' almost every aspect of evolution – from the universe in general to the various biological species on earth. Thus, the algorithmic information content of each alternative history of the universe merely gets a tiny contribution from the 'simple' basic laws, but a gigantic contribution from all the 'quantum accidents' that arise along the way!

A modern view of quantum mechanics

Some well-known paradoxes in quantum mechanics – the Schrödinger cat and the EPRB paradox in particular – have generated much controversy and learned discourse in the recent literature. In this book a new perspective is offered on these and related issues on the basis of Hugh Everett's theory of wave function of the entire universe, which has since been explored by many authors, including the famous Hawking–Hartle formulation with the same title. Gell-Mann and Hartle

have since investigated the foundations of quantum mechanics on these lines with a view to clarifying the working of the latter in the quasiclassical domain. Briefly, the picture which makes free use of the notion that *a given system can have different possible histories, each with its own probability*, is as follows: Suppose a set of alternative histories of the universe is specified, and that these histories are exhaustive and mutually exclusive. Rather paradoxically, quantum mechanics *does not always* assign a probability to each one. For a pair of such histories a necessary condition for a meaningful assignment of their respective probabilities is that they *do not interfere* with each other.

What is the condition of noninterference? The more fine-grained the history is, the more are the chances of interference. Therefore, in order to have actual probabilities it is necessary to consider histories that are sufficiently *coarse-grained*, since coarse-graining can wash out interference terms. In particular, if the interference term between each pair of coarse-grained histories is zero to a very good approximation, then all the coarse-grained histories are said to *decohere*, and one gets true probabilities.

But why does decoherence occur? It is the 'entanglement' of what is followed in the coarse-grained histories with 'what is ignored or summed over' that holds the key to the said mechanism. This does not give anything effectively new in the classical or quasi-classical domains, but helps solve several standard puzzles where quantum effects are apparently important. Thus, in the famous example of the Schrödinger cat, the alleged quantum interference between the live and dead cat scenarios can be explained away by the fact that there is plenty of opportunity for decoherence between the coarse-grained histories in which the cat lives and the corresponding histories in which the cat dies. Thus, the *live and dead cat scenarios decohere*, hence no interference.

By and large a very similar mechanism is involved in the Einstein–Podolsky Rosen–Bohm (EPRB) experiment concerning the decay of a spinless particle at rest into two photons wherein the state of polarization (circular or plane) of one is supposed to 'determine' that of the other. Now quantum mechanics says that both linear and circular polarizations cannot be simultaneously specified (these alternatives 'sit' on different branches of history, and cannot be considered together), while Einstein's 'completeness' would imply simultaneous assignments for both, perhaps through some 'hidden variable' mechanism. To distinguish between these two possibilities, Bell[12] had found some testable inequalities for the correlation function of the two photon polarizations wherein the latter could attain values in quantum mechanics that are not allowed in a classical hidden variable theory.

Subsequent experimentation (by Allan Aspect) confirmed the quantum-mechanical result, but led to a flurry of speculations about quantum mechanics showing bizarre properties, the implication being that measuring the polarization (circular or plane) of one photon somehow affects the other photon. On the other hand, there is nothing mysterious in all this according to the logic of decoherence given above, since the measurement process *does not* cause any physical effect to propagate from one photon to the other. Thus, if on a particular branch of history, the plane of polarization of the one photon is measured (and thereby specified with certainty), then on the *same branch* of history the plane polarization of the other photon is also specified with certainty. On a different branch of history, the circular polarization of one of the photons may be measured, in which case again the circular polarization of the other photon is also specified with certainty. This *does not* imply any *signal* from one photon to the other in the actual experiment; hence, no action at a distance is involved despite the seemingly instantaneous effect, implying faster-than-light propagation. Indeed, the physicist in the author comes down heavily on such distortions in the literature.

Summary and conclusion

As for the third and fourth parts of the book, no attempt is made at further abstraction, except to draw some conclusions from the author's own 'afterword' (Chapter 23): The book is *not* a treatise, but a running commentary on the various multidisciplinary researches in progress at the SFI. Running through the entire text is an essential 'interplay' between the fundamental laws of nature and the operation of chance, since the fundamental laws are quantum-mechanical, and quantum mechanics supplies only probabilities for alternative coarse-grained histories of the universe. This often results in their branching, with related probabilities. On certain branches and at certain times and places in the universe the conditions are ripe for the evolution of CASs which function best in a regime intermediate between order and disorder. They exploit the regularities provided by the approximate determinism of the quasiclassical domain, and at the same time they profit from the indeterminacies in their quest for 'better' schemata.

A CAS discovers 'regularities' in its incoming data stream by noticing features in common with its own, and emerges with a higher form of complexity through self-organization. When a CAS gives to a new kind of CAS, whether by aggregation or otherwise, the same can be considered a *gateway event*, e.g. the evolution of the mammalian immune system. And finally, many such features of biological evolution are found in other CASs such as human thought, social evolution and adaptive computing. All these systems keep exploring possibilities, opening up new paths, discovering gateways, and occasionally giving rise to new types of CAS. And the process goes on and on.

Looking back on this broad-spectrum book, one wonders as to what kind of clientele it is intended for, since, apart from the contents of Part 2, the rest of the book, by the very nature of its scope, is too full of definitions and *ad hoc* concepts to do 'coherent justice' to the vast canvas of material that the author has taken upon himself to present to the readership. This is certainly an unenviable task, for its theme is much more diffuse and tentative (many of the conclusions, in the author's own phrase, are the results of ongoing activities which are not yet firmly established) than e.g. the themes of other such books[6,7], which are more focused and based on firmer investigations. On the other hand, since the book is written in a nontechnical style, it must be assumed that it is meant for the widest possible audience, captive or otherwise. While the captive audience may be already aware of its contents along with the various jargons employed, one is not so sure if the general reader will find it equally enjoyable, despite the absence of technicalities. Moreover, the repeated emphasis on SFI and frequent references to the work of only a few personally known to the author (irrespective of the

depth of their investigations) does not quite make for a smooth reading from an educative angle, unless the reader were warned in advance that he was reading an autobiography.

Gell-Mann has long been my hero in physics, perhaps next only to Feynman and Dyson. I had richer expectations from the entire book but was only partially rewarded with Part 2 of it.

Functional Dynamics of Phytophagous Insects. T. N. Ananthakrishnan, ed. Oxford & IBH, 66, Janpath, New Delhi 110 001. 1994. viii + 304 pp. Price: Rs 550.

One-third of a million insect species are known to be phytophagous and constitute one-quarter of all living beings[1]. The number of recorded lepidopteran species alone, which are mostly phytophagous, is one order of magnitude greater than all species of birds and mammals put together – a staggering diversity which continues to overwhelm entomologists. The obvious success of phytophagy as a mode of life for insects testifies to their triumph in the evolutionary battle against plants. But plants have not been silent victims of insect onslaught either. They have waged their own evolutionary battle and what one sees today is a dynamic equilibrium in a continuing race. Interactions between insects and their host plants were first put into a comprehensive evolutionary perspective by Ehrlich and Raven's[2] classic paper, which triggered off an intense flurry of research activity. So strong has been its influence that almost all of plant morphology and plant secondary chemistry have since been attributed to selective pressure exerted by phytophagous insects. The book under review, coming close on the heels of another landmark publication in this area[3], is a laudable attempt at summarizing the mind-boggling literature on ecological and evolutionary aspects of insect–plant interactions.

Is geographic variation in plant allelochemicals of any significance to insect herbivores? In their chapter Johnson and Scriber address this question with examples from nonagricultural systems by dissecting out the ecogeographic variation in plant chemistry into historical, genetic, altitudinal and latitudinal factors. And how do phytochemicals alter insect behaviour? The chapter by Norris gives a brief overview of the major classes of chemical messengers, which is followed by a detailed discussion on the mechanism by which insects respond to chemicals. The idea that many common chemical messengers are both elicited and perceived by sulphydryl/disulphide-dependent mechanism of the receptors is convincingly argued. His call for detailed investigations of chemical communication at electrochemical level for a better understanding of cell–cell and environment–cell exchange of chemically based energy would hopefully attract more chemists to biology. The chapter on the physiological basis of feeding and oviposition behaviour in moths by Ramaswamy is an excellent review of the current knowledge on the role of proximate factors in host finding in moths. At the simplest level, host recognition and acceptance involves integration of inputs from several sensory modalities such as vision, mechanoreception and chemoreception. The internal metabolic state of the insect, the ontogenetic and phylogenetic influences on the mechanism of host selection add several levels of complexity to the dynamics of insect–plant interactions.

Do plants possess chemicals that provide both positive and negative stimuli and influence host selection? Dethier[4] had suggested that a balance of positive and negative stimuli could be present in the plants and the ultimate behavioural response of the insect depends on the balance between internal state of the insect as regards motivation and degree of satiety and external stimuli. This was further elaborated by Miller and Strickler[5], who proposed a 'rolling fulcrum model' wherein the internal excitatory/depressor factors could tip the balance in favour of host acceptance or rejection. This issue is examined by Renewick and Huang in the chapter on chemical stimuli mediating oviposition by lepidoptera. The authors review their work with the *Pieris–Crucifer* system, wherein the host plants have chemicals that are both oviposition stimulants and deterrents. Their results show quite convincingly that final rejection or acceptance of a host depends on the insect's assessment of the balance of stimulants and deterrents.

Ananthakrishnan, Venkatesan and Sridhar examine the effect of relative levels of nutrients and other chemicals like phenols, fatty acids and flavonoids in different plant parts on feeding and reproduction in the lepidopteran pest complex of cotton. The authors argue that this information can be of much use in managing insect pests of cotton by manipulating plant chemistry. Uthamasamy reviews the behavioural processes involved in host selection by the bollworm complex on different varieties of cotton. The emphasis here, however, is more on the effect of plant morphology on host acceptance by bollworms.

'Your enemy's enemy is your best friend.' That even plants believe in this is convincingly shown by Whitman and Nordlund in the seventh chapter. While reviewing the tritrophic interactions between plants, herbivores and their natural enemies, the authors present evidence to show that plants actually 'communicate' with natural enemies of their enemies, i.e. with the enemies of herbivores. Damage by herbivores induces the plants to produce chemicals that not only attract but actually serve as road maps to the natural enemies of herbivores. The chapter ends with a tempting speculation that these chemical beacons, 'kairomones' as they are called, hold great potential for solving pest problems.

Whitaker, Blum and Slansky Jr. attempt to trace the possible evolutionary path of

carnivory in phytophagous insects. The authors appeal for more careful and detailed study of such facultative carnivory since many instances of carnivory are either overlooked or not reported.

Another insightful and particularly enjoyable chapter also tackles the same theme, viz. plant defence against herbivores through tritrophic interaction. Whitman takes us on a fascinating journey into the world of plants and the elaborate strategies (nonchemical) employed by them to defend themselves against herbivores. The role of floral nectar, pollen, extrafloral nectaries, food bodies for ants, and domatia (shelters) in plant defence against herbivores by encouraging action of natural enemies is discussed in detail.

Interaction between gall-inducing insects and their host plants is reviewed by Raman in perhaps the toughest chapter, if one were to consider the extent of information published. The burgeoning literature on adaptional integration of host plant and galling insect species, host chemistry, chemical ecology of host selection, insect feeding, gall induction and the response of the host tissue is effectively summarized, but perhaps not sufficiently synthesized.

When two organisms are so closely linked as a plant and its insect pest/guest, the extinction of one is bound to increase the chances of extinction of the other. The issue of host specificity, metapopulations and conservation, using *Drosophila magnaquinaria* and its host plant as the model system, is addressed in the last chapter and the impact of small patches of host plants on the populations of the monophagous fruit fly is discussed.

All the chapters of this book, written by experts in their respective fields, are well researched. A more or less uniform presentation of chapters is also commendable for a multiauthored book as this one. The book, however, has its share of printer's devils. For instance, 'Lepidoptera' is spelt wrongly in the contents page and the legend to Figures on p. 253 is incorrect. Although each chapter can be read independently, they could still have been arranged into smaller subsections following a theme. Overall, the book offers a wealth of information to entomologists and will serve as an excellent companion volume to the recently published book on a related theme[3]. Undoubtedly, it should find a place on every library shelf. But unless publishers in India produce inexpensive paperback editions to accompany hard-cover library editions, the habit of buying books for personal use will surely go extinct.

The State of Food and Agriculture 1993. FAO Agriculture Series No. 26, Food and Agriculture Organization of the United Nations, Rome. 1993. 306pp.

The State of Food and Agriculture 1994. FAO Agriculture Series No. 27, Food and Agriculture Organization of the United Nations, Rome. 1994. 357pp.

The Food and Agriculture Organization of the United Nations (FAO), established in October 1945 for helping to achieve freedom from hunger and to disseminate widely data and information relevant to this basic goal, completes 50 years of service this year. Since its establishment, FAO has been publishing a wide range of journals, reports and books. Invariably, these are the most authentic sources of data available in the world concerning area, yield, production, prices, imports and exports, and other relevant information relating to agriculture, forestry and fisheries. FAO has also an early warning system to draw attention to hot spots in the field of agricultural production so as to help in taking proactive steps to avoid famines. Early warning systems also exist in the case of pest epidemics. A good example is the locust warning system. As it celebrates its 50th Anniversary, FAO can look back with satisfaction on the varied services it has rendered to member nations and more particularly in the field of communication and publication. Most of the FAO publications, including the books under review, are now available as electronic products.

The books under review bring together in a very readable form the significant developments in agriculture during the preceding years. The reports are structured in a way that they contain generic information as well as specific data relating to regions and countries. In addition, one major issue is taken up for detailed analysis in each of the reports. For example, the 1993 report deals with water policies and agriculture, while the 1994 report pays specific attention to various development and policy dilemmas in the forestry sector. The reports give the reader in a capsule form the situation on the food front. FAO's definition of agriculture includes all land- and water-based occupations such as crop husbandry, animal husbandry, fisheries and forestry. Both production and trade issues are considered. The economic environment under which agriculture progresses is often dealt with in an objective manner.

The special sections on water and forests in the 1993 and 1994 reports have one point in common. They both emphasize the need for community participation in the sustainable management of these two essential foundations for sustainable advances in agricultural production. Unless there is equity in sharing the benefits, the requisite degree of public cooperation in managing these assets will not be forthcoming. Participatory water and forest management involves a paradigm shift in management culture, moving away from an entirely government-controlled management to the involvement of all the stake holders in both decision-making and implementation mechanisms.

On the occasion of the 50th anniversary of FAO, the question can be asked as

to why endemic hunger arising from undernutrition and malnutrition is still widely prevalent, although the founding fathers of FAO had felt even in 1945 that the world has the requisite technical and financial resources to make hunger a problem of the past. Is this situation due merely to a lack of the requisite will at the national and global levels to give operational content to the political slogan of 'food for all'?

On the basis of a recent study, the International Food Policy Research Institute (IFPRI), located in Washington, DC, USA, believes that by the year 2020 significant reductions can be made in poverty, food insecurity, malnutrition and micronutrient deficiencies and significant advances made toward efficient, effective and low-cost food and agricultural systems that are in harmony with the natural resource base. The fact remains that although today the world produces enough food to feed each and every person, nearly 800 million children, women and men remain food-insecure. The reasons for this tragic irony are to be found in the nonfood sector, such as lack of purchasing power and entitlements, poor sanitation and health care and non-availability of clean drinking water. It is, therefore, time that we redefine our concept of food security as '*livelihood security for the households and all members within, which ensures physical and economic access to balanced diets, including the needed micronutrients, safe drinking water, environmental sanitation, basic health care and primary education*'. Such a redefinition will help to articulate the public policy package needed to ensure food security at the level of each individual in a household. The emphasis on individuals rather than on families is important, since in many societies women and girl children tend to suffer more from undernutrition and malnutrition and there is a trend towards an increasing feminization of poverty.

How do we achieve this goal? In October 1995, a meeting of representatives of Member-Nations of FAO will be held at Quebec in Canada to commemorate the signing FAO's Charter in that city in October 1945. This is an appropriate occasion to analyse why the Freedom from Hunger Campaign launched in the early sixties by the late Dr B. R. Sen when he was the Director-General of FAO is still to achieve its objectives. The 50th Anniversary of FAO is best commemorated by the adoption of a *Global Convention on Sustainable Food and Livelihood Security*. Such a convention can include the following major provisions:

1. Implement both in letter and spirit the plans of action agreed to at recent UN Conferences, particularly at Rio, Cairo and Copenhagen and take speedy action to implement the provisions of the Desertification Convention.

2. Ensure adequate support for research and development efforts designed to promote national and international public good, since the fast-spreading Intellectual Property Rights (IPR) environment is likely to promote greater investment only in short-gestation-period and profit-driven research. Integrating the dimension of sustainability in research objectives, however, involves location-specific and participatory research with rural families. This kind of research is unlikely to attract adequate investment from the corporate sector.

3. Ensure the rapid dissemination of environmentally sound agricultural technologies, particularly among resource-poor farm families, who may have difficulties in gaining access to green technologies as a result of the provisions of the Trade-related Intellectual Property Rights (TRIPS) of the World Trade Agreement.

4. Promote increased trade in value-added agricultural commodities produced in developing countries by assisting them in improving post-harvest technology and sanitary and phytosanitary measures.

5. Contribute generously to global emergency food security reserves and to Food for Livelihood-Security Programmes through the World Food Programme and other appropriate global, regional and national protective social security programmes, so that every child, woman and man has the requisite entitlements for a healthy and productive life.

I would suggest that the State of Food and Agriculture Report for 1995 could include in its special topic section a discussion on the scope and need for such a global convention for the elimination of hunger.

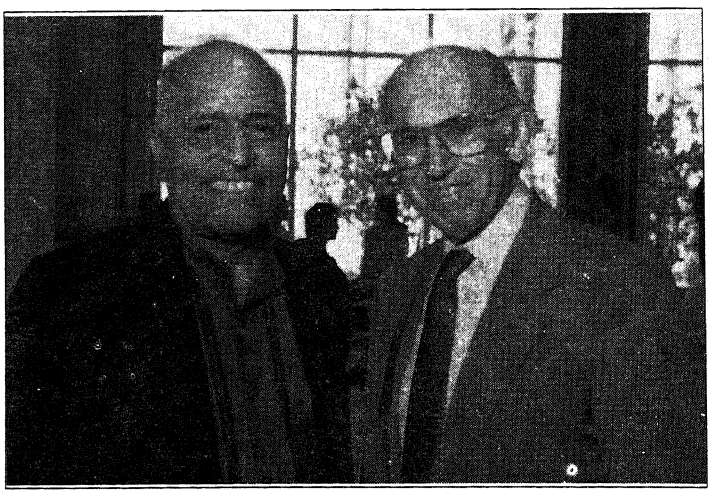
A visionary and courageous scientist

An obituary of Jonas Salk



Jonas Edward Salk, a visionary and courageous scientist who invented the first vaccine to protect children (and adults) against the crippling disease poliomyelitis, passed away in La Jolla on 23 June at the ripe age of 80. His contributions are monumental and in countries continuously using the Salk vaccine the result was an initial drastic reduction in the incidence of the disease and, thereafter, total eradication of polio. He was also a builder of institutions and had to his credit the founding of the well-known Salk Institute for Biological Research.

His incursions in vaccinology began in 1942 at the University of Michigan, where he helped develop a commercial vaccine against the influenza virus. Several thousand soldiers in the US Army were immunized with this vaccine employing a potent immunopotentiator similar to Freund's incomplete adjuvant. A follow-up of these subjects 25 years later did not indicate any incidence of cancer or abnormality attributable to this immunization. Based on these observations he questioned the wisdom of not using such adjuvants for obtaining high and long-duration response with vaccines destined for human use. Before his death, he was deeply involved in making a vaccine against HIV in which he was intending to use this adjuvant.

In 1947, Jonas Salk moved to Pittsburgh in a faculty position as the Head of the Virus Laboratory. It is here that he started work on the polio vaccine, which received impetus from President Roosevelt, who had himself been a victim of polio. His researches were generously funded by public and private funds, prominent amongst which was a grant of $ 7.5 million from the March of Dimes campaign launched by the National Foundation for Infantile Paralysis. In an amazingly short period of 8 years, in a promotional climate free from obstructions, his vaccine passed from laboratory to human trials. The results of the large-scale trial announced in 1955 were impressive. The vaccine conferred 80–90% protection. Imbued with humanitarian concern, he did not patent the vaccine nor made money from it. It was licensed to six companies on easy terms for large-scale availability to the public. By 1960, the incidence of polio declined by 92% in the United States. President Eisenhower awarded him the Congressional Medal for Distinguished Civilian Achievement. It was taken up for immunization of children in other countries with equally impressive protection rates and fall in incidence of the disease. The French Govt. conferred on him the Legion d'Honneur for his work of international significance.

Then came a setback for no apparent fault of Salk. One of the batches of the vaccine manufactured by a company failed to kill the virus completely and the vaccine caused unforeseen deaths of about 300 recipients. The government imposed a ban on this vaccine in USA, even though it continued to be in use in Canada, Holland, Scandinavia and some other European countries. Meanwhile, a rival vaccine developed by Albert Sabin became available and was introduced in USA in 1961 based on trials conducted in USSR. The Sabin vaccine consisted of three strains of live *attenuated* polio viruses, in contrast to the Salk vaccine, which employed *killed* viruses. The Sabin vaccine had the ease of oral administration, whereas the Salk vaccine required to be injected. The counterpoints were that the Sabin vaccine demanded to be kept frozen to remain active, whereas the Salk vaccine did not require the 'cold chain'. The mode of action of the two vaccines was also somewhat different. The Salk vaccine, by systemic immunization, generated antibodies and cytotoxic cells, inactivating and killing the infecting polio virus. No live virus was released in the stools. The Sabin vaccine sought to induce local immunity in the gastrointestinal tract against the infectious virus. The live attenuated polio viruses present in the vaccine, however, colonized in the gut and were released to the environment in faeces. It was conceived that these viruses would be taken by others in the community and would hence create 'herd' immunity over and above the individuals immunized.

On face value, the Sabin vaccine was cheaper and appeared to be more suitable for general immunization programmes in children. However, trials conducted by Dr S. Bhallaya at the All India Institute of Medical Sciences, New Delhi, and by Dr Jacob John at the Christian Medical College, Vellore, showed the superiority of the Salk vaccine for inducing antibodies against the polio viruses as compared to three doses of the Sabin vaccine given orally. Similar results were reported from Algeria. The relative poor immunogenicity of the Sabin vaccine was not ascribable to the improperly frozen vaccine in the above-mentioned trials conducted by experienced virologists. It is surmised that five doses of the oral vaccine may be necessary for satisfactory sero-conversion of the children.

Jonas Salk (right) with the author at the 5th International Congress of Immunopharmacology at Tampa, Florida (1991).

This does pose practical difficulties of repeat visits and compliance in the expanded programmes of immunization. These difficulties are further compounded by the uncertainties of availability and maintenance of cold chain for this vaccine in far-flung rural areas. Thus, after due scrutiny of the data, the Indian Council of Medical Research recommended the use of the Salk vaccine as such or as adjunct to the Sabin vaccine. An opportunity to make the Salk vaccine in the country, along with two other cell-culture-derived vaccines against measles and rabies, came forth in 1989 with the French company Merieux agreeing to be a partner in a venture along with the Department of Biotechnology, Indian Petrochemicals, and 25% shares accessible to public for investment. Jonas Salk (and others including me) played an active role in motivating Merieux to come to India with a technology that will be useful for more than one vaccine of proven efficacy. An agreement was signed in New Delhi by the President of Merieux with counterpart officials in the august presence of President François Mitterand and Prime Minister Rajiv Gandhi. Had this agreement materialized, India would have been the largest producer of these vaccines in the world, meeting its own needs and exporting to other countries. Merieux had a further proposal of making a quadruple vaccine comprised of DPT (diphtheria, pertussis and tetanus) along with the Salk polio vaccine. Thus, complete immunization of the child against these four killer diseases could be accomplished with a common vaccine. A cherished goal of researchers and public health organizations is to have a vaccine with multiple components to prevent all childhood infections by a single intervention. Technologies are evolving to deliver multiple doses of the vaccine in biodegradable microspheres at a single contact point.

Jonas Salk was a pioneer vaccinologist. He was also a thinker and theorized on the implications of scientific findings on man and his place in society. He authored four books in this context: *Man Unfolding* (1972); *The Survival of the Wisest* (1973); *World Population and Human Values* (1981) and *Anatomy of Reality* (1983). He rallied readily for public causes. In spite of specialized focusing that any notable scientific work demands, his outlook was broad. He had a sensitive personality, and was at home amongst writers, artists and thinkers. He married in 1970 an equally lovable person, Françoise Gilot, an artist and a writer (*My Years with Picasso*) who was for many years a companion of and lived with Pablo Picasso. He is survived by three sons from his first wife.

Although Jonas Salk did not get the Nobel prize, he received several recognitions. In 1975, he delivered in New Delhi the Jawaharlal Nehru Award Oration for International Understanding.

In response to the havoc that AIDS was causing worldwide, he got energized in the last years of his life to make a vaccine against this 'clever' virus, which attacks and incapacitates the host immune status. With his demise, his ambition remains unfulfilled.

A doyen of Indian physicists

An obituary of S. D. Chatterjee

Professor Shyamadas Chatterjee, a doyen of Indian physicists, passed away in Calcutta on 27 May 1995 at the age of 86.

Born on 29 June 1909, he studied at Cuttack, Patna and then at Presidency College, Calcutta, obtaining his B Sc degree in 1930 and M Sc degree in Physics from Calcutta University in 1932. Among his teachers was none other than C. V. Raman, who on winning the Nobel Prize in 1930 graciously acknowledged the letter of congratulation from his young student. Chatterjee joined the Bose Institute, founded by the pioneer Jagadish Chandra Bose in 1938, and showed his experimental skills by constructing one of the first Wilson cloud chambers in India. For his research on cosmic rays he was awarded the D Sc degree of Calcutta University in 1945, his examiners being Blackett and Cockroft.

When the news of the discovery of nuclear fission reached India, he set up his own experiment with indigenous components to detect the emitted neutrons. He was thus the first one to detect the spontaneous fission of uranium in 1940. For the interpretation of his experimental results he was indebted to S. N. Bose. His brief communication to *Science and Culture* was, however, withdrawn as it had been sent without the permission of the then Director of the Bose Institute! His estimate of the half-life of uranium was a few orders of magnitude less than the value of Teller but was verified by Georgy Flerov from the Soviet Union within a few months. The actual calculation of the half-life from the detector counts was done by N. R. Sen of the Department of Applied Mathematics. In return Chatterjee repaired Sen's radio set, an indication of how scientific collaboration worked in those days! Chatterjee was awarded the Woodburn Medal of Calcutta University for best research in 1948 and the Elliott Medal of the Royal Asiatic Society in 1951.

In 1949 Chatterjee went to Chalk River, Canada, and also visited several laboratories in the USA, including the National Bureau of Standards, where he interacted with Tuve. He maintained contact with

leading scientists like Herzberg, Marton and Mott throughout his life.

Satyendra Nath Bose had moved back to Calcutta from Dacca in 1945 and recruited Chatterjee as Lecturer in the Department of Pure Physics in 1951. He was later promoted to Reader. He set up the first radiocarbon dating laboratory in India and detected fall-out across the country from atmospheric nuclear tests conducted in the early fifties.

Chatterjee was known for his brilliance in electronic instrumentation and built his own GM and proportional counters, picking up the coincidence counting technique from Walter Bothe in Germany. He worked as Fellow in The Davy–Faraday Laboratory of The Royal Institution, London, in 1958 when Lawrence Bragg was the Director. During one of his visits to Europe he is credited with the suggestion of the possibility of recoil-less emission of gamma rays from the nucleus, which led to the discovery of the Mössbauer effect. In recognition of this, he was invited to Munich as a Visiting Professor in 1964.

Chatterjee was invited to head the Physics Department of the newly constituted Jadavpur University in 1956 and built up the department with energy and devotion. His group discovered very high helium content from the emanations at the hot springs at Bakreshwar near Calcutta. For enriching the gas he set up his own laboratory which was later taken over by the Department of Atomic Energy. His research interests expanded into experimental solid-state physics, his students studying exo-electron emission from GM electrodes, surface states in semiconductors and metal–semiconductor contacts. He guided over 60 doctoral theses and was a kindly father-figure, ever ready to advise and support financially researchers in need.

On retirement from Jadavpur University in 1969, he joined his mentor S. N. Bose at the Indian Association for the Cultivation of Science as Senior Fellow and again set up a helium laboratory. He continued to guide research students, his encyclopedic knowledge of physics being always available to colleagues and students. A small laboratory was even set up in his own house and run by the S D Chatterjee Foundation.

He was elected Fellow of the American Physical Society and Fellow, IEEE and was one of the seniormost Fellows of the Indian National Science Academy. A bachelor with spiritual leanings, Chatterjee donated his house to the Asiatic Society Calcutta, one of the oldest institutions pursuing knowledge in all its aspects.

A probe into the Calcutta earthquake of 1737

Pitta Govinda Rao

Some doubts have been expressed in the recent literature about the occurrence of an earthquake that occurred simultaneously with a cyclonic storm during September/October 1737 near Calcutta. In this article an attempt has been made to probe into the historical documents with a logical analysis. Our study reveals that an earthquake did occur undoubtedly near Calcutta in 1737. However, the death toll reported in the catalogue of significant earthquakes by the US Department of Commerce needs to be corrected. It was also found that the Encyclopedia Britannica has missed to make entry of the earthquake, in addition to making inadvertently a wrong entry of the date of occurrence of the cyclonic storm. This study has led to the conclusion that an earthquake did occur near Calcutta during the passage of a severe cyclonic storm on the Bengal coast on the night of 11 October 1737 as per the Gregorian equivalent calendar, or on 30 September 1737 as per the then-existing Julian calendar. The death toll due to the combined disaster could have been about 3000.

The United States Department of Commerce in their catalogue[1] of significant earthquakes for the period 2000 BC–1979 has made an entry of an earthquake occurrence near Calcutta on 11 October 1737. Recently, some scientific groups[2,3] have expressed doubts about the occurrence of this event. The suspicion was mainly due to the death toll reported in this document and the mismatch of the dates of occurrence in other sources of literature. Due to the coincidence of the earthquake event with a severe cyclonic storm that crossed the Bengal coast[4], it is felt necessary to investigate further to make the picture more transparent. In the process, the author has reviewed all the available literature related to the earthquake from the recent to the historical times[5]. An independent approach was adopted and reported briefly earlier[6]. In this article, an attempt has been made to give detailed information on the event. The author was fortunate to get all the necessary literature at the University of East Anglia, UK.

Main reports

The US Department of Commerce in their catalogue[1] of significant earthquakes, published in 1981, have included the occurrence of an earthquake on 11 October 1737 near Calcutta. The location was given as 22.5°N, 88.4°E and the number of deaths reported was 300,000. The damage caused has been rated as 'moderate', corresponding to a property loss of 1–5 million US dollars of 1979.

Encyclopedia Britannica of 1974 (ref. 7) mentioned only the occurrence of a cyclonic storm on 7 October 1737, causing a 12 m storm surge and killing about 300,000 people, and termed it as the most catastrophic cyclone.

Blanford, a meteorologist working in India, in his catalogue[8] of 1877 has included the occurrence of the cyclone storm on 7 October 1737 and described it as follows: 'This storm is ranked among the worst, if not the worst, tropical cyclone disasters in recorded history.' The death toll given by him was 300,000.

In 1848, Peddington[9] in his *Hornbook* stated clearly about the simultaneous occurrence of an earthquake and a cyclonic storm on 11 October 1737. He did not make any entry about the casualty figures.

Earlier, in 1837, Martin[10], in his *Medical Topography of Calcutta* writes:

> 'The earliest notice I can find of a storm and earthquake occurring together is – On the night between 11 and 12 October 1737, there happened a furious hurricane at the mouth of the Ganges which went 60 leagues up the river. There was at the same time a violet earthquake, which threw down a great many houses along the riverside in Golgota (i.e. Calcutta) alone, a port belonging to the English.... Dutch ships in the river, three were lost, with their men and Cargoes: 300,000 souls are said to have perished. The water rose 40 feet higher than usual in the Ganges.'

Gentleman's Magazine of June 1738 describes about the damage caused due to a furious hurricane in the Bay of Bengal and a violent earthquake on 30 September 1737. However, no death toll was included (a copy of the report from the magazine is given in Appendix 1).

Bengal Public Consultations, dated 15 October 1737, published in another source in 1906, states as follows:

> 'The late violent storm laid the whole black towns, quite throughout the honourable company's (The East India Company) bounds, insomuch that hardly twenty thatched houses were standing the next day, and the inhabitants lost the little they had and were rendered incapable of paying the rents ... what still adds to the calamity is that by the violent force of the wind the river overflew so much that a great quantity of rice was quite spoiled... and nearly 3000 inhabitants were killed, and a great number of large cattle besides goats and poultry destroyed.'

Discussion

It is evident from these reports that an earthquake did occur during September–October 1737. However, unfortunately, for reasons not known, reports earlier to 1974 do not provide the sources from where the information on the disaster was collected. If we analyse in the reverse order, i.e. from the historical times, we find that Martin[10] has nowhere indicated that he had collected his data from a journal published in 1738. He had added and exaggerated the information on death toll (from 3000 to 300,000) from an official source, *Bengal Public Consultations*, dated 15 October 1737. A close comparison of these sources clearly reveals that Peddington[9] reproduced the occurrence of the events from Martin's book[10]. In both Martin's and Peddington's reports, the date of occurrence of the storm and the earthquake was given as 11 October or the night between 11 and 12 October 1737. Blanford, without referring to any earlier reports, has reported the occurrence of a cyclonic storm on 7 October 1737, without any explanation regarding the date of the event[8]. Literature study reveals that he has taken the information from Peddington[9] and altered

JUNE.

ON *September* 30, laſt happened a furious Hurricane in the Bay of *Bengal*, attended with a very heavy Rain, which raiſed 15 Inches of Water in 6 Hours, and a violent Earthquake, which threw down abundance of Houſes; and as the Storm reached 60 Leagues up the River *Ganges*, it is computed that 20,000 Ships, Barks, Sloops, Boats, Canoes, *&c.* have been caſt away. A prodigious Quantity of Cattle of all Sorts, a great many Tygers, and ſeveral Rhinoceroſes were drowned; even a great many Caymans were ſtifled by the furious Agitation of the Waters, and an innumerable Quantity of Birds was beat down into the River by the Storm. Two *Engliſh* Ships of 500 Tons were thrown into a Village above 200 Fathom from the Bed of the River *Ganges*, broke to Pieces, and all the People drowned pellmell among the Inhabitants and Cattle. Barks of 60 Tons were blown two Leagues up into the Land over the Tops of high Trees. The Water roſe in all 40 Foot higher than uſual. The *Engliſh* Ships drove aſhore, and broke to Pieces, were the *Decker*, *Devonſhire*, and *Newcaſtle*; and the *Pelham* is miſſing. —— A *French* Ship was drove on Shore, and bulged; after the Wind and Waters abated they opened their Hatches, and took out ſeveral Bales of Merchandize, *&c.* but the Man who was in the Hold to ſling the Bales ſuddenly ceaſed working; nor by calling to him, could they get any Reply; on which they ſent down another, but heard nothing of him, which very much added to their Fear; ſo that for ſome Time no one would venture down: At length one more hardy than the reſt, went down, and became ſilent and unactive as the two former, to the Aſtoniſhment of all: They then agreed by Lights to look down into the Hold, which had a great Quantity of Water in it, and to their great Surprize, they ſaw a huge Alligator ſtaring as expecting more Prey: It had come in thro' a Hole in the Ship's Side, and 'twas with Difficulty they killed it; when they found the three Men in the Creature's Belly.

Wedneſday, 7.

On the 2d and 7th of this Month happened great Diſputes in the Court of Common Council of the City of *London*, concerning Propoſals for performing the Maſons Work of the intended Manſion-Houſe for the Lord Mayor; and on the Diviſions, one Party appeared in behalf of the Propoſal of Meſſ. *Townſhend*, *Horſenail*, and *Taylor*, three of their own Body, to do the ſaid Work for 17200 l. and the other Party for 250 l. cheaper. Some Perſons thinking it extraordinary that Gentlemen ſhould be for the higheſt Price, and alſo that it might carry a Reflection, as if thoſe propoſed to take the loweſt, were not able to do the Work ſo well as the others; inſerted in the News Papers the Oath of a Common-Councilman, diſtinguiſhing the Clauſe following in a different Character.

Good and true Counſel ye ſhall give in all things touching the Commonwealth of this City, after your Wit and Cunning: And that for Favour of any Perſon, ye ſhall maintain no ſingular Profit againſt the common Profit of this City. A Liſt alſo was handed about of 7 Aldermen, and 110 Commoners who divided for the higheſt Price, all, but about 20, of which Liſt are diſtinguiſhed to be of ſome of the Committees for adminiſtring the City Affairs; and, what is pretty remarkable, they are diſtinguiſhed, who voted on the firſt Diviſion for the loweſt Propoſal, *viz.* Sir *John Barnard*, (Lord Mayor) Sir *Robert Godſchall*, *Daniel Lambert*, and *Robert Weſtley*, Eſq; Aldermen. Dep. *Joſeph Ayliff*, Dep. *Tho. Sandford*, Dep. *Sam. Tatem*, Mr *Robert Henſhaw*, and Mr *Hen. Siſſon* Common Council-men.

The firſt Diviſion, *June* 2. was,

—— For the higheſt Price 80.

—— For the loweſt 63.

Tt The

some details and reported as independent information. He changed some quantitative information; for example, in the statement '... the storm reached 60 leagues up to the river Ganges ...' 60 leagues has been changed to 60 miles (a league is equivalent to about 3 miles).

Logical analysis reveals that *Encyclopedia Britannica*[7] contains the information given by Blanford, including the date of occurrence and the death toll[8]. Since Blanford's interest is only for the weather-related phenomena, he has excluded the earthquake occurrence. The report of the US Department of Commerce also mentions the death toll as 300,000 due to an earthquake on 11 October 1737. This document quotes several references[12–17] as sources of information. After a thorough study, the author is inclined to conclude that the source of information for these reports is also the report of Martin[10].

The next question which arises is about the date of occurrence. It is evident that after a century of occurrence, Martin reported[10] the date of the events of cyclone and earthquake as the night of 11 October 1737. It is important to note that he has taken care of the change of the calendar by the Britishers. The Gregorian calendar was not in use in British Empire in 1737 and the date 30 September is according the Julian calendar then in vogue. It matches very well with the date 11 October 1737, which would be its Gregorian equivalent[4], but not the 7 October as mentioned by Blanford. The present author, while looking at the historical source[5], *Gentleman's Magazine*, was astonished to see the total absence of any estimate of lives lost in the combined disaster (Appendix 1). This led him to search further and find the official figure of death toll in the combined tragedy as 3000 in another source[11]. In this, a letter written more than a year after the disaster, on 29 January 1739, describes:

> '... the storm which levelled most of the walls in the town, shattered and threw down many of the buildings and blew up the bridges, the tide some days after broke in upon and carried away some of the wharfs, ships and stairs, the places most damnified are the peers on the factory wharf, wharf and ships at Soota Loota. Walls around the burying place and powder magazine and factory points, Church steeple was overthrown.'

The above description enriches the knowledge for supporting the occurrence of an earthquake along with the storm. Further, in an economic study of Bengal, Bhattacharya[18] mentions that only after the great disaster of 1737 was widespread masonry construction considered desirable. These observations give a fairly good qualitative idea that destruction to buildings might have occurred partly due to ground motion. Bilham[2], while concluding that 'the listing of this event in the catalogues of disastrous earthquakes is indefensible', writes that 'the possibility that an earthquake-induced *tsunami* caused the flood damage cannot be completely excluded'.

Population estimates range from 10,000 to 12,000 between 1705 and 1720 (ref. 19). It has been documented[20] based on the report by Ray[21] that the population of Calcutta was 120,000 in 1757. It was further mentioned that 'the early nineteenth century may not have held for the 200,000 or so who were living in Calcutta, in an environment largely of British creation'[20]. From these facts it is clear that the number of people dead in the disaster *cannot* be 300,000 as reported by the *Encyclopedia Britannica* and by the US Department of Commerce. The author, therefore, feels that the official figure of 3000 might have been exaggerated to 300,000 by Martin[10].

Conclusion

After spending sufficient time in reviewing the literature from the historical past to the present, the author feels confident in stating that an earthquake did occur in the vicinity of Calcutta on the night of 11 October 1737 as per the Gregorian equivalent calendar, or on 30 September 1737 as per the then-existing Julian calendar. Exaggerating the death toll figures is a human psychology, even today, for drawing the attention of the targeted groups. It is also evident that the earthquake occurrence was during the period of landfall of a cyclonic storm on the Bengal coast. The concerned authorities of the *Encyclopedia Britannica* and the US Department of Commerce may consider issuing a modification to their reports, after another independent study, if felt necessary.

DEPARTMENT OF SCIENCE AND TECHNOLOGY

JSPS RONPAKU (DISSERTATION Ph D) FELLOWSHIPS: 1996–97

Department of Science and Technology (DST) invites applications from promising and qualified young researchers for JSPS RONPAKU (Dissertation Ph D) Fellowships: 1996–97, offered by the Japan Society for the Promotion of Science (JSPS) within the framework of India–Japan Cooperative Science Programme (IJCSP). Four Fellowships are available.

Description of the Ronpaku programme

RONPAKU programme provides support to researchers who wish to obtain their Ph D. degrees from Japanese universities through the submission of dissertation, without going through the course work.

Grantees under this RONPAKU programme (RONPAKU Fellows) are required to conduct dissertation research under the joint supervision of a Japanese Advisor and an Indian Advisor. For this purpose, during the maximum period of five years, the RONPAKU Fellow will visit Japan once a year to conduct research at a Japanese university under the supervision of the Japanese Advisor, who will visit the RONPAKU fellow's country, when necessary, to supervise the research together with the fellow's home advisor.

Fields

All fields of Science & Technology

Eligibility

Applicant should

1. be a citizen of India;
2. have already achieved substantial research results and, through dissertation research under the programme, be deemed likely to obtain a Ph D degree successfully;
3. be holding a regular position as a researcher in a recognized scientific/technical institution in India;
4. be able to forward the final application through proper channel of the Parent Institution.

Japanese Advisor

The Japanese Advisor must be either a professor, associate professor or lecturer who teaches in the doctoral course of a graduate school of either a national, public or private university in Japan.

Supervision of research

During the overall tenure of 5 years, the RONPAKU fellow will visit Japan once a year for a maximum period of 90 days per visit, to conduct research under the supervision of the Japanese Advisor.

The Japanese Advisor may visit the fellow's country, not more than once a year (for a period of 7–30 days per visit) to supervise the research in accordance with the plan approved.

Terms of awards

JSPS provides the following financial support:

To the RONPAKU fellow

1. Round-trip economy class air ticket between India and Japan.
2. Maintenance allowance as per JSPS regulations.
3. In Japan, research trip allowance of up to Yen 100,000 per visit to Japan once a year.
4. Sickness and accident insurance fee during the stay in Japan, as per JSPS regulations.
5. Expenses related to dissertation submission and publication in the final year of the fellowship tenure, as per JSPS regulations.

To the Japanese Advisor [when visiting the fellow's country]

1. Round-trip economy class international airticket between Japan and India.
2. Maintenance allowance for stay in India.
3. Supervising expenses (when receiving a RONPAKU fellow).
4. Research allowance for supervising the RONPAKU fellow.
5. Supervising expenses.

Application procedures

The Application Forms can be obtained from the Programme Office, India–Japan Co-operative Science Programme (IJCSP), International Division, Department of Science & Technology, Technology Bhavan, New Mehrauli Road, New Delhi 111 016 by sending a request along with a self-addressed envelope (12 cm × 27 cm) entitled "JSPS RONPAKU Fellowship 96–97."

The filled application forms should be forwarded by the candidate through proper channel latest by 15 October 1995. INCOMPLETE APPLICATIONS WILL BE SUMMARILY REJECTED. Applicants will be notified of the results by the end of March 1996.

IPS-11

July 28–Aug 02, 1996
Bangalore, India

Eleventh International Conference on Photochemical Conversion and Storage of Solar Energy (IPS-11)

Scientific Programme

The IPS conferences are held every two years with the aim of outlining the latest developments in the field of photochemical conversion and storage of solar energy. The eleventh conference of this kind will cover the following areas:

* Photoinduced electron transfer processes
* Photocatalysis in heterogeneous and homogeneous systems
* Photoelectrochemistry
* Photosynthesis in biological and biomimetic systems
* Quantum chemical studies of molecules on surfaces under the influence of light
* Thermodynamic aspects of quantum solar energy conversion
* Environmental applications of photocatalytic systems
* Materials for photoenergy conversion and photochemical engineering

These topics will be discussed in plenary and at invited lectures, workshops and poster sessions. Contributions from participants are encouraged. A book of abstracts will be distributed at the conference.

Location

The Eleventh International Conference on Photochemical Conversion and Storage of Solar Energy (IPS-11) will be held in the National Science Seminar Complex, Bangalore, India.

International Organizing Committee

E. Amouyal (France): C.A. Bignozzi (Italy): M. Calvin (USA); G. Calzaferri (Switzerland): Y. Cao (China); M. A. Fox (USA); M. Fujihira (Japan); D. Gust (USA); G. Hodes (Israel); V. Krishnan (India); J.-M. Lehn (France); N. S. Lewis (USA); S. E. Lindquist (Sweden); A. Nozik (USA); V. N. Parmon (Russia); E. Pelizzetti (Italy); Sir G. Porter (UK); N. Serpone (Canada); H. Tributsch (Germany); F. Wilkinson (UK); H. Yoneyama (Japan); F. Willig (Germany); K. I. Zamaraev (Russia)

Local Organizers

S. Umapathy and P. K. Das, Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore.

Second Circular

The second circular containing more details will be sent by October 1995. The Organizing Committee would appreciate your supplying this information to others who may be interested in attending the IPS-11.

In this issue

Quest for quantum gravity

This issue carries an article by Gary K. Au (**page 499**) on the 'Quest for Quantum Gravity'. It is an extended exposition of some current efforts towards the Holy Grail of theoretical physics. The article makes a real effort to aim at the reader outside the field, and is also unusual in avoiding the impersonal style of the textbook and the research journal, by using detailed extracts from interviews with three of the many people who have spent time on this quest – Chris Isham of Imperial College, London, Abhay Ashtekar of Pennylvania State University, and Edward Witten of the Institute of Advanced Studies, Princeton. We therefore have an interesting contrast in emphases, viewpoints and style. The article does not portray the field as a finished product but is a report from the frontline, so to speak. It will be interesting to see how much of what is described will seem outdated ten or even five years from now, and how much will survive.

R. Nityananda

Fall of liquid drops

The phenomenon of a liquid drop falling under gravity in another immiscible liquid medium is, in fact, a complex one. In general, the drop may deform considerably or even break up, the motion may be unsteady or oscillatory and the wake may even be turbulent. For sufficiently small drops, however, these pathologies are absent and the motion is steady with only slight deformation of the drops. A natural question to ask then is: What is the nature of the drag force on a drop under these circumstances?

In this issue (**page 534**) G. J. Srinivasan and P. Satyanarayana present the results of a detailed experimental study aimed at determining the drag force on a falling drop. They show that although, in general, many more dimensionless groups are involved, for the range of Reynolds numbers, Morton numbers and Eotvos numbers considered, only three are really relevant. Moreover, using data obtained from 21 liquid systems, they show that the relationship between these three yields an explicit expression for the drag force, a quantity of considerable practical interest. One should note that this expression holds even when the drops deform slightly provided the equivalent diameter is used. The authors point out that their results provide a means for measuring the density of liquids available only in microquantities when other conventional methods may fail.

P. N. Shankar

Measuring single-ion activities

Solutions of electrolyte were considered non-ideal, since the change in chemical potential of these solutions was not found to be equal to $RT \ln m$. To account for this, Lewis proposed an empirical correction factor, γ, called the activity coefficient and considered $m\gamma$ to be the effective concentration. The reason for the non-ideal behaviour of electrolyte solution was explained as being due to electrical interaction between ions by the Debye–Huckel limiting law. Thus, the concept of activity coefficient of ions gained a rational basis. However, the activity of a single ionic species remained a theoretical idea since it could not be measured experimentally and the measurable mean ionic activity was used in theoretical calculations.

Activity coefficient is conveniently measured by the EMF of galvanic cells with or without transference. The former involves a junction between two solutions and hence a liquid junction potential (LJP). The latter also includes LJP due to the contact between the reference electrode solution and the electrolyte solution and the electrolyte of the half cell under test. Evaluation of LJP needs a knowledge of single-ion activity (SIA). Thus, one faces a vicious circle when an attempt is made to measure SIA.

In this issue (**page 529**) S. Parthasarathy and K. Ramya propose an interesting solution to overcome this problem. They eliminate liquid junction by using a bridge of solid silver chloride, which is a solid-state ionic conductor. Using this idea, they have measured SIA of Zn^{2+} and Cl^- in $ZnCl_2$ solutions and the results are discussed in this paper. An interesting observation from the results is that the activity is seen to be equal to $Z_i^2 mr_i$ and not mr_i, lending support to the view of Parthasarathy and Srinivasan published in *Current Science* (1994, **66**, 56–59).

SYMPOSIUM
on
U. N. BRAHMACHARI & PERSPECTIVE OF KALA-AZAR RESEARCH

Indian Institute of Chemical Biology
Calcutta 700 032

Date: 3–4 November 1995

TOPICS OF SCIENTIFIC SESSIONS

1. History of Kala-azar research and contributions of Professor Brahmachari
2. Clinical profile of the disease including PKDL
3. Epidemiology and transmission dynamics of the disease
4. Chemotherapeutic approach
5. Vector biology and control
6. Immunobiology of host–parasite interaction
7. Biochemistry and molecular biology of Leishmanial parasites
8. Pathophysiology of Leishmaniasis
9. Diagnosis
10. Control

Address for correspondence:

Dr. M. K. Basu/Dr. H. K. Majumder
Indian Institute of Chemical Biology
4, Raja S. C. Mullick Road, Calcutta 700 032
Phone: 473-6793/0492/5197, Fax: 473-5197/0284

CURRENT SCIENCE

NEWS

ISI's electronic library

First announced in August 1994, the Institute for Scientific Information's Electronic Library Project[1] has made considerable progress in its first year.

The project in which IBM and Lotus collaborate with ISI, aims to deliver complete information to customers' desktops. The prototype consists of *Current Contents/Life Sciences* edition, providing table of contents, bibliographic data, and abstracts for 1350 journals, with the addition of full images of those articles for which publishers have agreed to allow electronic storage and delivery.

All aspects of the prototype are now in place. IBM offers technical advice and components for storage, retrieval and delivery of information in a distributed environment which will seamlessly plug into various existing library WAN/LAN topologies. Lotus Notes Desktop software will be used by pilot sites at eight locations – six in North America and two in the UK – which have agreed to test the prototype.

ISI chose Lotus Notes as it is the leading client/server platform for developing and deploying groupware applications, and it has the capacity to deal with large amounts of full-imaged data and to track usage statistics. Besides, it is easily integrated into ISI's prototype, and provides the level of security needed for the content providers, viz. the journal publishers.

ISI has invited over 360 publishers, representing the 1350 journals indexed in *Current Contents/Life Sciences*, to participate in this venture. Two Indian journals, *Journal of Biosciences* and *Journal of Genetics*, both published by the Indian Academy of Sciences, are among the journals that have agreed to make full text images available to clients of ISI's electronic library. The eight pilot sites that would test the prototype are Brookhaven National Laboratory, Lehigh University, the New York Public Library, Purdue University, SmithKline Beecham Pharmaceutical R&D, Thomas Jefferson University, University College in London, and Glaxo Research and Development Ltd.

The test phase of the prototype has begun and will last for eighteen months. The test phase aims to shed light on practical applications such as data access, retrieval and usage. Input from library communities and publishers will help clarify issues such as copyright, intellectual property, pricing and usage patterns, that are key to the commercial success of the project.

The cornerstone of the project is the construction of an economic model that will facilitate pricing that will be acceptable to the information providers and the users. The project will measure the economics involved, weigh the need for security vs access, and will measure and assess usability. ISI's prototype electronic library can test:

1. Technical systems required to support electronic journal delivery (data access, storage and delivery)
2. Internal systems required to facilitate implementation of the electronic library – including billing, accounting and business management reporting
3. Economic models that will meet the diverse needs of the publishing and user communities
4. Behaviour of users to determine how the electronic journal may change the traditional information purchasing and usage patterns.

The economic model is based on several assumptions

1. The *Current Contents* database will be a site license.
2. Pricing for the electronic journals will be subscription-based and will be set by the publisher.
3. Royalty payments for documents ordered through the system will be set by the publisher. ISI will set a processing fee.

The prototype will provide for seamless network integration through a network-based client/server system that can be added to and coexist with the customer's current local area network. The ISI server at the pilot site will be capable of supporting heterogeneous clients, e.g. Windows, Macintosh, OS/2, etc. For reasons of security, data transmission will be via dedicated ISDN lines and not through Internet. The network uses the standard TCP/IP both for communication between Central Server and Customer Server and for traffic between Customer Server and Desktop.

In a way, the seeds of the idea of an electronic library were sown more than 50 years ago, when in 1954, Gene Garfield wrote as the first Grolier Society Fellow at Columbia University that 'the ideal library must be able to supply information instantaneously [and] satisfy a wide variety of information requirements for a population that will be highly intellectual and scientifically trained'. The founder of ISI then used the term 'library system for the year 2045!' Now it appears, thanks to developments in information technology and the growing demand for accurate information to meet specific demands, that his dream will come true 50 years earlier than anticipated by him and others.

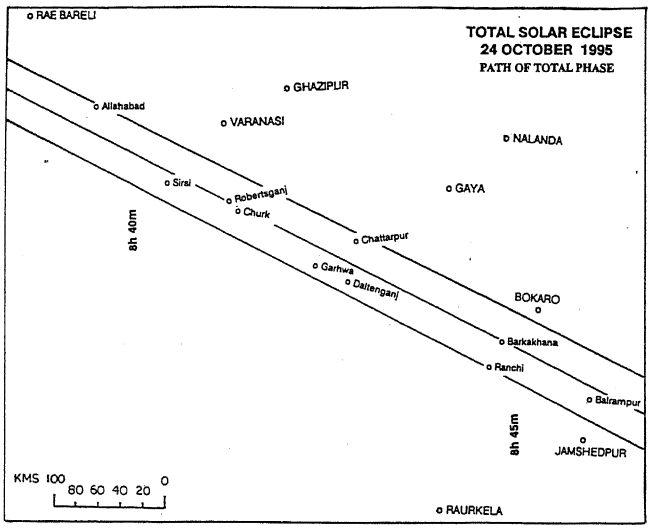
Total solar eclipse – October 1995

On October 24 this year, the track of totality of a solar eclipse will cross a 40–55 km wide strip of land in northern India. Total eclipse may be seen from any location within this strip, which will stretch from Rajasthan in the west to West Bengal in the east. The beginning of the eclipse will be over Iran at sunrise, and will end over the Pacific Ocean at sunset. In India, the total phase will be visible between 8.30 and 8.50 in the morning as the shadow will sweep over the country; the duration of totality on the centre line will range from 45 s over Rajasthan to about 80 s in West Bengal. Full details of the visibility of the eclipse have been calculated and given in the NASA Reference Publication No. 1344 (ref. 1). Weather conditions over the path are expected to be favourable[2].

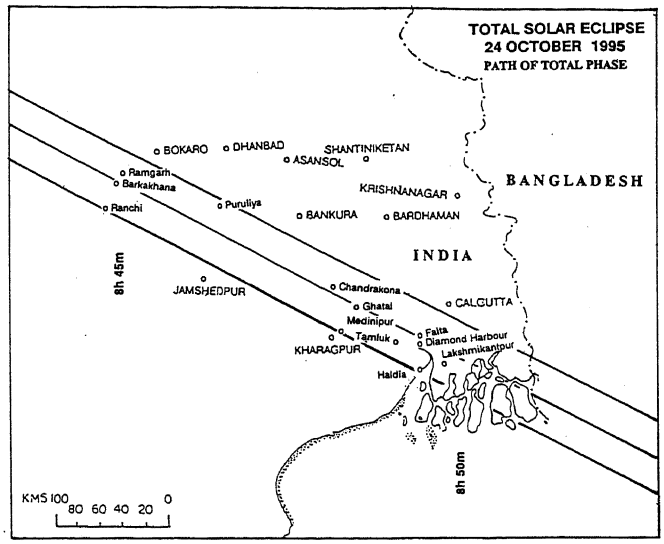
One point about total solar eclipses often missed is that the view of the totally eclipsed sun cannot be obtained from outside the track of totality; what one can see is only a partially eclipsed sun. A few accompanying features such as considerable diminution of daylight, perhaps even a view of a few bright stars and planets may be seen, but most of the spectacles, the chromospheric flash, the glorious view of the corona, etc., will be missed. But these views are so rare that many who had stayed outside the track do not even realise what they have missed. I have come across many persons who claim to have witnessed a total eclipse, but on scrutiny it has come out that they have witnessed only a partial phase of the total eclipse. The records in such cases reveal that the track of totality of that particular eclipse did not pass through the city where they were located.

The chances of an eclipse track passing over a particular spot are very rare; statistical calculations indicate that on an average the chances are roughly once in 350 years. We may check the rate by comparing the visibility chances at a few particular spots. This year the track will pass slightly south of the city of Calcutta; the last time such an event was seen from this locality was on 10 May 1575 during the reign of Akbar, the Mogul. The last time an eclipse track passed within 50 km of Bangalore was on 5 July 1293; the city was not even founded. The next time it will be on 5 July 2168, a really long wait indeed!

But as in all statistical figures, certain extremes are unavoidable. In recent history, two eclipse tracks crossed over Newfoundland in the eastern coast of Canada within two years and four months, i.e. on 7 March 1970 and 10 July 1972. Still more strange is a spot in Siberia, where three eclipse tracks passed over within eleven years, viz. 1941, 1945 and 1952.



As far as the subcontinent of India is concerned, calculations reveal that during the twentieth century, eclipse tracks should pass over part of it just five times. Three events are already over; two, including the one this year, are yet to happen. The first was on 21 August 1914, when the track ended over the Rann of Kutch at sunset. The second, a similar one on 30 June 1954 had the path of totality slightly north, which again ended at sunset over the Rajasthan desert. The third one was the best among the five; its duration was about 3 min and the totality path crossed over Karnataka, Andhra Pradesh, and Orissa, and again over a short stretch over Mizoram. It happened in the afternoon with the sun still high in the sky and provided a unique opportunity of viewing the beauty of totally eclipsed sun to millions on its track. It is beside the point that countless numbers deprived themselves of this chance because of blind superstition.



For this year's eclipse, detailed maps showing the eclipse path in India have been given by Singh[3]. I am giving only some important points about the event from the viewpoint of observers from India. The first glimpse of totality will be from a village Anandgarh on the Indo-Pak border at 0830 IST, with the sun 20° above the horizon; its duration will be about 45 s. Two fairly big towns in Rajasthan, Alwar and Bharatpur will fall in the eclipse path though not on the centre, as a result of which the duration of totality for viewers located at these places will be reduced. The cities of Agra and Etawah will fall just outside the path, while Allahabad and Mirzapur will be just inside; but to get a good view of the eclipse the viewers will have to move some 10–15 km to reach the centre of the eclipse path. In Bihar, both Ranchi and Hazaribag will fall a few km outside, so also the metropolis of Calcutta, whose southern suburban area will be just inside the eclipse path. Duration here on the centre of the track will be about 80 s, with the sun's altitude about 40° at mid totality.

After this year's eclipse, one more eclipse track will cross over India in the late afternoon of 11 August 1999. The course of the shadow will cross Gujarat, Madhya Pradesh and Andhra Pradesh and will end at sunset over the Bay of Bengal. But considering the seasonal chances of monsoon clouding over the eclipse path and the lower altitude of the sun in that event, this year's eclipse appears to be the last good chance for Indian scientists in this century for arranging experiments which will hopefully produce some vital clues to the mystery of the sun.

The scientific explanations for the occurrences of total eclipses and various observable events are available in the literature; scientific experiments undertaken during such events are also extensively covered in some review articles[4]. We may skip those points to avoid unnecessary repetition and concentrate on various features observable by amateur astronomers and general viewers. We may carefully note one warning: looking at the bright disc of the sun without protection is hazardous. During an eclipse event, most of the time the uneclipsed part will be visible, it may only be viewed through a heavily darkened filter. The type of goggles which the welders use are quite suitable; they cut down the brightness to about 10^{-4}, which is essential. An alternative can be prepared by exposing black and white photographic films to daylight (not direct sun) and developing them fully in the dark room. The films can then be fixed in hypo, washed and dried in air. One layer may not provide the extinction needed; two or three layers mounted together may be necessary. The sun through this composite may look brownish and can be viewed without any discomfort.

Once armed with this device, we can venture to view an eclipse event. Let us imagine that we are located at the centre of the path of totality. The invisible moon will be approaching the sun from the west; the first contact will appear as

an almost unnoticeable dent in the solar disc. Minute by minute the eclipse will grow; slowly we will be able to recognize the dark shape of the moon. The moon appears here as pitch dark, even though considerable light reflected from the earth illuminates its face. This appearance is purely due to contrast to the uneclipsed part of the bright photosphere.

Not very spectacular things seem to have happened as yet: there is a gradual decrease in general illumination and the air temperature starts falling, and this can be felt. I have been told that confusion can be noticed among flocks of birds and herds of cattle at the untimely appearance of the dusk, but am unable to describe in proper sequence from my own experience, because whenever I faced such a situation in the past, I was much too occupied and worried about my experiments to pay attention to these details. But one does not miss some amount of eerieness in the atmosphere at that time.

Something noticeable happens in the shadows cast by obstacles. If we have a tree nearby then through some gaps in the foliage tiny bits of sunlight fall on the ground. In normal times these take the form of diffuse circles of light but now one may clearly notice sickle-shaped light spots instead. In fact, these are pinhole images of the partially eclipsed sun through the narrow openings in foliage. It is as expected from the laws of physics, but nevertheless quite striking in appearance.

Now let us turn our attention to the sun; the sun is already in a crescent form, something similar to the crescent moon, only the edges are much sharper. They get thinner and thinner and ultimately break up into a string of bright beads; these are called Baily's beads after the scientist who first described the phenomenon in 1836. The appearance is due to unevenness of the lunar limb; the photosphere may shine through small valleys for a few seconds more after almost the entire disc has been covered by the moon. Sometimes the presence of a deep valley may produce a 'diamond ring' event, when just one very bright point as if mounted on a ring of pink chromosphere may be seen. Any idea of the beauty of this diamond ring is difficult to convey to a person who has not seen it.

One more interesting piece of observation may be made at this juncture; bands of light and shadow may be seen on the ground, rippling all over. There are different appearances of these shadow bands, and in that unreal atmosphere the observers imagine different things. Some see them as if standing in a snake-pit with vipers crawling all around, and some see the event as faint shadow ripples passing under their feet. The phenomenon is similar to the twinkling of stars and owes its origin to the irregular refraction by atmospheric eddies. The only difference is that shadow bands cast in the light of bright stars are not detectable in reflected light, but the tiny Baily's beads are much brighter and the bands created in their light are easily detected by unaided eye.

The pink chromosphere flashes out as soon as the photosphere is covered; if the sun is active, a few prominences, plumes of glowing solar gas stretching out of the limb may be seen. The view lasts for one or two seconds only, but this short stretch of time is most eagerly awaited by solar physicists, ever since Janssen and Tennant did the pioneering experiments on the tobacco fields of Guntur on the morning of 18 August 1868, when a new element helium was discovered, 27 years before it was detected in a British laboratory by William Ramsey.

For amateurs and general eclipse viewers I may safely recommend an interesting observation. The only instrument one will need is a pocket-sized direct vision spectroscope. One should keep looking through this instrument at the thinning crescent sun; the protective dark filter should be removed; the spectroscope will disperse sunlight automatically bringing down its intensity to a safe level. One will see dark Fraunhofer lines clearly; the moment the photosphere is covered by the moon, all dark lines will flash into an array of vividly coloured emission lines. This experiment was first performed by C. A. Young of Princeton University during the eclipse of 22 December 1870, and ever since it has been repeated almost in all eclipses, not only for the valuable information about the detailed structure

of the solar chromosphere but also for the sheer magical beauty of the event.

As the moon will cover up the thin chromosphere, the pink light will fade and be replaced by the pearly white glow of the solar corona. I must repeat that the protective dark filter will have to be removed during totality, otherwise all of these interesting views will be missed. The size and shape of the corona varies from eclipse to eclipse, depending upon the phase of the solar activity cycle. At sunspot maximum the corona will be extensive and covers all sides, while at minimum it generally avoids polar regions and extends mainly over the solar equator. This year's eclipse will be near a sunspot minimum and the latter shape is expected. But even then, the glow of the corona will prevent the sky from becoming totally dark; there will be almost as much light as that from a full moon, but it will be more mysterious, more ethereal, spinning a web of fantasy over the whole atmosphere.

The pictures of the solar corona we see on the pages of astronomy textbooks are far from inspiring, most of the intricate beauty being lost in the recording process. But the eye can perceive many details of streamers and rays, and catch the subtle display of light and its variations over the precious seconds of totality. Of course, the new recently developed techniques of scientific processing of the coronal photographs in the laboratary can bring out part of the lost information, though not the beauty of the grandest spectacle of nature.

The totality ends rather suddenly, with a brief appearance of chromospheric glow, Baily's beads and, if lucky, with a diamond ring event; then one can see even the moon's shadow racing away, and daylight reappearing like a flood. The eclipse is over, although the crescent sun will take almost an hour more before assuming the normal full disc form.

It is indeed a pity that many persons refuse to see the total eclipse because of superstitious ideas. Some think that harmful radiations emanate from the sun during eclipses; some even go to the extreme of imagining that poisonous gases pervade the earth's atmosphere. The unusual happenings in the sky used to strike terror in the minds of primitive men, who imagined demons devouring the sun and eventually destroying everything; the customary penances and ritual baths after the event are remnants of the original feeling of terror. The ideas of a demon devouring the sun have largely disappeared, but the fear of the unknown persists. I know persons who not only refused to observe the eclipse, but kept their entire families locked indoors to prevent them coming under the influence of the eclipse; even tiny holes in their windows were plugged to stop the light from the eclipsed sun to enter their homes. It is difficult to explain to them that nothing happens to the sun during eclipses; the shadow cone cast by the moon is always floating in space, and this just goes over the earth's surface during eclipses. Even the idea of generation of poisonous gases or bacteria in the shadow cone is unscientific; the earth also carries its own shadow cone on the night side, everyday we are living in it for twelve hours. It is futile to point out that these ideas are totally based on ignorance and have no trace of scientific logic. The persistence of the feeling is aided by the extreme rarity of the phenomenon; for people rooted to their homestead, the chance of viewing a total eclipse comes once in fourteen generations.

Many point out the occurrence of eclipse blindness which had totally spoilt the eyesight of many persons in the past. This fear is genuine but need not be attributed to any strange unnatural phenomena during eclipses. The real reason lies in the extreme brightness of the sun; if any person keeps on looking at the sun, his retina will also get burnt out, causing blindness. In normal times physiological reflexes prevent such mishaps but during the penultimate minutes just prior to totality, general illumination falls and human iris opens up to collect as much light as possible in the rapidly darkening surroundings. But the crescent sun retains the same intrinsic brightness per unit area, and its image focused on the retina with the fully opened eye-lens burns out a sickle-shaped area of the sensitive tissue. The dangerous aspect of this accident is that the observer does not feel any pain, and the damage is done without the viewer's knowledge. Prevention of such happenings is simple and has been prescribed earlier in this article. Nothing happens to the skin or any other part of the body by exposure to the eclipsed sun.

To conclude, I may say that this is a rare opportunity for many to witness an event which I may call as Nature's grandest spectacle. I am still to meet any person who has gone and witnessed a total solar eclipse, and repented the trouble and extra effort needed for his adventure.

On the eve of the total solar eclipse of 16 February 1980, Dr M. K. V. Bappu had addressed the Osmania University faculty and the students; I feel his concluding advice may be retold now. An excerpt below gives beautifully what I wish to convey to all enthusiastic viewers:

'I now think of the man who enjoys some of the nice sights of Nature, one who has got an aesthetic sense of feeling of appreciation of beauty, who enjoys a good sunset, who finds a feeling of delight at hearing the roaring waters of a waterfall or of a gurgling stream as it passes by, who delights in a good rainbow or takes a fancy for seeing the well-spun cobweb of a spider on a dewy morning; in short, an individual who is alert to his environment and who enjoys different aspects of it. I think there is much for him in witnessing one of these rare sights of the total eclipse of the Sun. I hope that he would just travel down not very far, just even twenty miles south of Hyderabad and take with him, probably a minimum of equipment, just his own eyes, and go through this delectable feast that is really only a feast of the Gods.'[5]

I have only to substitute the city of Hyderabad by a chain of cities in North India for this year's eclipse; otherwise, the advice remains the same for millions who do not wish to miss an opportunity of a lifetime.

10th Himalaya–Karakoram–Tibet Workshop, Switzerland, 1995 – Conference report

Since 1985, a series of international annual meetings on the geology of the Himalaya–Karakoram–Tibet region have been held: Leicester, UK (1985); Nancy, France (1986); London, UK (1987); Lausanne, Switzerland (1988); Milan, Italy (1990); Grenoble, France (1991); Oxford, UK (1992); Vienna, Austria (1993); and Kathmandu, Nepal (1994). The 10th Himalaya–Karakoram–Tibet Workshop was held at Monte Verità, Ascona city, in Switzerland on April 3–8 1995. This was the second time that the Swiss held the Workshop, and it was organized by David Spencer, Jean-Pierre Burg and Cinzia Cervato-Spencer of the Institute of Geology, Swiss Federal Institute of Technology (ETH), Zürich. A combination of several factors made this meeting very successful. The ETH geologists have a long record of research in the Himalaya. Augusto Gansser (now 85) is a pioneer Himalayan geologist. His book *Geology of the Himalayas*[1] is a cornerstone of our geologic knowledge of the Himalaya. Gansser, former Chairman of the ETH Institute of Geology and now a retired Emeritus Professor, opened the Workshop with a fascinating talk on his 60 years of geologic work in various parts of the Himalaya, including his visit to the holy mountain of Kailash in 1936. Gansser and Arnold Heim (the son of the famous alpine geologist Albert Heim) published the results of their field work in Darjeeling, Kumaun and south Tibet in a treatise, *Central Himalaya*[2], an original and pioneering piece of work.

The Workshop was well organized. It was held in a charming spot in Switzerland: the ETH Conference Centre at the Alpine hilly station of Monte Verità facing the blue lake of Maggiore. Fees for accommodation and food were subsidized. And more important, 25 participants came from the Himalayan countries – thanks to the fund-raising efforts of the conveners. Some 144 participants from 17 different countries in Europe, North America and Asia attended the Workshop.

The Himalayan Workshops are a timely response to increasing interest among geologists in the Himalaya and Tibet. With an area of some 2.5 million km^2, a mean elevation of 5000 m above sea level and crustal thickness of about 70 km, the Tibetan Plateau is the world's largest highland. Its geological genesis is still an enigma. The Himalaya bordering the southern margin of Tibet is the loftiest and youngest mountain chain on earth. These spectacular mountains hold crucial keys to understanding how mountains resulting from the collison of continental plates form. They are also linked in many ways to the ecology and life in south Asia. Rivers, rain-bearing monsoon clouds, and sediments coming from the Himalaya support agricultural communities, accounting for more than 10% of the world's population; they are also responsible for the formation of the world's largest delta (the Ganges Delta) and the largest marine fan (the Bengal Fan). In recent years, it has also been suggested by Raymo *et al.*[3] that the uplift and erosion of high mountains, especially the Himalaya–Tibet region, initiated the ice ages in the northern hemisphere during the past 3 million years. This is possible because high rates of chemical weathering and denudation absorb atmospheric carbon dioxide. This hypothesis was recently featured in a BBC documentary entitled 'Tibet: The Ice Mother', which was also shown at the Workshop.

It was, therefore, appropriate that a special session of the Workshop (with 10 oral presentations) be devoted to 'Geological processes related to uplift, exhumation and elevation of the Himalaya, Karakoram and Tibet'. This author began the session by presenting a sequential history of the uplift and denudation of the Himalaya throughout the Cenozoic, and emphasizing that the rise of the Himalaya seems to have occurred episodically in several distinct phases rather than a steady-rate slow history, a single big boom or merely chaotic events here and there. A one-hour Discussion Meeting had also been scheduled to discuss informally 'The mechanisms and consequences of Tibetan plateau uplift', led by Peter Molnar, a geophysicist who has been pondering on the geodynamic evolution of the Himalaya and Tibet since the early 1970s (Molnar and Tapponnier's influential paper[4] in *Science* is a must to read). During discussions on the uplift history, it seemed that two major ideological camps among Himalayan researchers exist: those who confine the uplift of the Himalaya and Tibet to the Miocene epoch (23–5 Ma) (e.g. Molnar), and those who also add a major Quaternary (the past 1.6 million years) phase of uplift to this history (e.g. Gansser).

We know that the Himalaya grew out of the closure of the Tethyan Ocean, which once lay between India and Asia. We also know that the initial boundary between the Indian and Asian tectonic plates, along which Tethys was consumed and subsequent India–Asia collison took place, is represented by the Indus–Tsangpo Suture Zone, first suggested by Gansser in 1964. But the timing of this collision is controversial. Richard Beck of the University of South California presented a summary of his research group's recent paper[5] in *Nature* presenting stratigraphic evidence from the Indus Suture Zone in Pakistan that the collision took place between 65 and 57 million years ago (Ma) at least in northwestern Himalaya. Previously, Searle *et al.*[6] had argued that the collison was at 50 Ma. Another one-hour discussion was devoted to 'The timing of the India–Eurasia collision', headed aptly by Searle and Beck. Much stimulating discussion followed, and with a mood of 'back to the basics', the very definition of 'continental collision' was questioned. 'Continental collision' goes through an early stage of 'ocean floor termination', i.e. when the basaltic ocean floor is completely consumed by the process of subduction, and a later 'continental suturing', i.e. when the shallow marine facies changes into purely continental sedimentation. Beck defined the 'collision' as the former, and Searle as the latter. But why not consider both of them as initial and end

members of 'continental collision'? – ocean floor termination initiating the deformation of the colliding continents, prominently involving the accretionary prism, although shallow marine sedimentation is still going on, and continental suturing giving rise to land conditions at the site of the collision. There may be a time span of several million years between these two events. In other words, drifting and converging continental plates 'hit' each other before they actually 'meet' each other.

The Himalaya as we know consists of a series of fold-and-thrust belts. The backbone of these mountains is the Central Crystalline Zone of the Higher Himalaya, which has thrust over the Lesser Himalayan sediments and low-grade metamorphosed sediments along an orogen-scale rupture known as the Main Central Thrust (MCT). Some 20 years ago, Le Fort[7] proposed a model according to which simultaneous metamorphism and thrusting along the MCT brought 'hot' rocks of Higher Himalaya over the 'cold' Lesser Himalaya, causing an 'inverted metamorphism', i.e. metamorphism temperature–pressure conditions increasing upwards the mountains. This model was put forward to answer the enigma of inverted metamorphism in the Himalaya, first observed by several geologists in the late 19th century. There are, however, several other models to explain inverted metamorphism, including granitic intrusions in the Higher Himalaya, differential thrusting of each metamorphic zone, large-scale folding of metamorphic isograds, and ductile shearing distributed across the Central Crystalline rocks. Several talks addressed these issues, and a one-hour Discussion Meeting was devoted to '20 years of MCT models – Which ones work?'. It seems that to relate the Himalayan inverted metamorphism to the MCT a clear definition of the MCT along the strike of the Himalaya is required (Mr. X's MCT in Garhwal may be entirely different from Mr. Y's MCT in Nepal and hence confusing debates) and then it should be considered whether the MCT is a unique single structure in terms of Himalayan metamorphic history or rather a wide zone of multiple thrusts and shearing. Systematic thermochronological and thermobarometric data across the Higher Himalaya are also required to address the 'puzzle' of inverted metamorphism. In the end, we may find that each model, like the four blind men in the famous Indian parable, touches a certain aspect of 'the elephant' and conveys some but not all of the truth, of course with all the likeliness that some of the models are more truthful than others.

John Ramsay, a well-known structural geologist who succeeded Gansser at the ETH Institute of Geology and is now retired (himself succeeded by Jean-Pierre Burg, a convener of the Workshop) gave an overview of the discussions during the four-day Workshop. Ramsay remarked that as Emile Argand's 1916 map of the western Alps has changed little after eight decades, Gansser's 1964 geological map of the Himalaya is essentially valid to this day. What aspects of Himalayan geology may be expected to yield novel discoveries in the future? From the standpoint of structural geology, Ramsay emphasized the need to study the deformation history within the geological divisions of the Himalaya rather than merely viewing each orogen-scale division as an intact unit.

The Abstract Volume was published as No. 298 issue of *Mitteilungen aus dem Geologischen Institute*, ETH (349 pp). A proceedings volume of the Workshop containing selected, referred papers is scheduled to be published in *Tectonophysics* in 1996. A total of 48 oral presentations were made in 10 sessions: Tectonics and Palaeoclimate (2 talks), Southern Tibet (4), Tibetan Plateau (3), Himalayas of Pakistan and India (14), the Main Central Thrust (4), Central and Eastern Himalaya (14), Asian tectonics (4), and Applications of geochronology in the Himalaya (3). Some 52 posters were displayed and each poster was given three minutes to convey its main message, which was a good strategy to handle poster presentations. Overall, the coverage of topics was well balanced, although at the end of the Workshop there was criticism that usually in the Himalayan Workshops much attention is paid to 'hard rock' geology, while many important clues to understand the evolution of the Himalaya are hidden in its sedimentary record ('soft rock' geology). Interestingly, this criticism was made by two stratigraphers, Aymond Baud (Switzerland) and aurizio Gaetani (Italy) as well as by a tectonist, Vikram Thakur (India).

Most of the Indian participants at the Workshop came from the Wadia Institute of Himalayan Geology (Dehra Dun) and the Birbal Sahni Institute of Palaeobotany (Lucknow), which are, in my opinion, two of the best geoscientific research institutions in India, aptly named after the great Indian scientists: D. N. Wadia (1883–1969) and Birbal Sahni (1891–1949). India with its vast resources in Himalayan geology should try to hold one of the Himalayan Workshops in the future – before the new millennium begins!

A good beginning

Current Science deserves appreciation for the courage and the cudgels it has taken up to improve the standards of teaching science and scientific research in our universities. There is no gainsaying the fact that owing to several articles published in *Current Science* in the last two years or so the subject of deteriorating quality of science, both teaching and research, in our universities is no more a sacred cow. Several conscientious academicians have voiced their opinion that the onus for this unsatisfactory state of affairs, several things apart, lies to a fair degree of measure on the scientific and teaching community also[1,2]. It is heartening to see that in terms of objectivity and critical appraisal of scientific research being conducted in our universities and research institutions, the articles published in *Current Science* score over those which appeared sometime back in *Nature*[3], in which every thing about scientific research in India was goody goody and the other side was totally overlooked. Lack of critical self-appraisal, which, of late, has come to pervade our scientific and educational institutions of higher learning is one of the important causes of our mediocrity in these areas. It is high time that we get ourselves rid of this malady lest it is passed on to our future generation of teachers and scientists. In this regard we need to take a lesson from S. Chandrasekhar, whose recounting of the story of Daedalus and Icarus elegantly brings out how critical self-appraisal is fundamental to all good research and advancement of science[4].

The initiative of the Council of the Indian Academy of Sciences to improve the standards of science education in the country is timely and the agenda enunciated in the 'Academy Paper'[5] is both laudable and challenging. If the articles published in *Current Science* have struck a chord in the hearts of our young researchers and teachers then, probably, a good beginning has already been made.

Does low serum cholesterol increase suicide and aggressive behaviour?

Amar Bavle

It is a well-established medical fact that high serum cholesterol is a risk factor for developing ischaemic heart disease and that lowering the high level of serum cholesterol in these patients reduces mortality. Interestingly, follow-up studies showed no overall reduction in the mortality rates. A meta analysis of six primary prevention trials of cholesterol-lowering agents in men (pooled $N = 24,847$) by Muldoon *et al.*[1] revealed that the intervention group experienced reduction of deaths from heart disease compared to controls but the total mortality remained the same. This means that with reduction of serum cholesterol, mortality from other causes increases.

This prompted a detailed examination of the causes of noncardiac mortality. Epidemiological studies have examined the relationship between nonmedical mortality and baseline low serum cholesterol in the general population. The Varmland study in Sweden by Lindberg *et al.*[2] and the study of Neaton *et al.*[3], both in 1992, screened more than 350,000 men and showed a higher mortality in men with low serum cholesterol. Most unexpectedly, the higher mortality from noncardiac causes was found to be mainly due to suicides and traffic accidents and aggression as well. A higher risk of suicide and deaths from accidents were reported from a meta analysis that pooled the results of 18 prospective epidemiological studies[4].

More recent findings[5] suggest that men with serum cholesterol levels at or below the 25th percentile were twice as likely to have ever made a serious suicidal attempt compared to men whose serum cholesterol was above the 25th percentile. They have proposed that low serum cholesterol is a potential biological marker of suicidal risk.

Is it possible to explain the increased suicide rates in people with low serum cholesterol? There is an interesting hypothesis to explain this. The explanation invokes the serotonin hypothesis of depression, suicide and impulse control disorders (which includes aggressive behaviour). All these conditions are associated with low serotonin levels in the brain and low serotonin levels in the human brain are associated with poorer suppression of behavioural impulses

like suicide and aggressive behaviour[6].

There is evidence that low serum cholesterol is associated with a number of aggressive behaviours. For example, varied psychiatric disorders where aggression is an important symptom, like in male homicidal offenders who are habitually violent under the influence of alcohol[7], and male criminals with antisocial personality disorder who are aggressive[8]. Even from animal experiments there is some evidence that a cholesterol-reducing diet in monkeys makes them more aggressive[9]. A low cholesterol diet in monkeys is also associated with low brain serotonin levels[10]. Both suicide and aggressive behaviour, therefore, are associated with lower serum cholesterol possibly reducing brain serotonin levels[6].

In summary, there is evidence that noncardiac deaths, particularly suicides, occur not only in patients receiving cholesterol-lowering drugs but also in people whose serum cholesterol is naturally low. Interestingly, for some unknown reason, this effect is much more pronounced in men than in women. The question that is yet to be answered is: Is it correct advice to tell people to keep their cholesterol levels low? Cardiologists will invariably say yes, because it reduces mortality from cardiac conditions. It would be wiser to review the answer in the light of recent findings and look at it from all angles rather than just the narrow cardiac viewpoint.

It would be interesting to examine to what extent these patterns are seen in the Indian population. These investigations have recently been undertaken.

Bose–Einstein condensation in a dilute atomic vapour

N. Kumar

A team of researchers working at the Joint Institute for Laboratory Astrophysics (JILA) in Boulder, Colorado, has just announced[1] having observed three distinct signatures for the occurrence of Bose–Einstein condensation (BEC) in a dilute ultracold vapour of atomic rubidium-87 (^{87}Rb). The most distinctive signal claimed for the onset of the BEC was an abrupt appearance (and gradual growth) at (and below) a threshold temperature of an anisotropic momentum distribution sharply peaked about zero against a diffuse, isotropic thermal background that reflected the lowest-energy *single*-particle state, now being occupied *macroscopically* (i.e. extensively) by the bosonic ^{87}Rb atoms. And that is precisely what the Bose–Einstein condensation is all about – a *macroscopic* (*finite* fraction of the total) number of particles occupying the lowest-energy *single*-particle state, leaving the higher states sparsely populated.

The experiment involved (i) confining a sample of about 2000 ^{87}Rb atoms to a volume about 10 μm across, thus compressing the vapour to a number density of about 2.6×10^{12} cm^{-3}, and (ii) cooling it to an abysmally low temperature of about 170 nk and maintaining the BEC so obtained for a reasonable length of time of about 15 s for diagnostic studies. All this necessitated a synergetic combination of novel experimental techniques for trapping and cooling of atoms. Thus, the magnetic trap used was essentially a quadrupolar magnetic field that dotted with the antiparallel-aligned magnetic moments of ^{87}Rb atoms ($F = 2$, $m_F = 2$) so as to give a confining potential well. This potential well, however, had at its central minimum the magnetic field equal to zero, allowing the atoms to flip their moments freely through unavoidable perturbations and escape. This *leak* was *plugged* in an ingenious manner by superimposing a rotating magnetic field, slow enough for the moments to follow adiabatically but fast enough to yield a time-averaged orbiting potential (TOP) which was parabolic, and with a non-zero averaged magnetic field at the minimum that prevented the spin flip. The TOP was a uniaxial 3D harmonic potential giving an oblate ground state wavefunction. The latter was reflected in the anisotropic momentum (velocity) distribution of the BEC recorded by shadow imaging. As for the cooling, the atomic gas was precooled by the laser Doppler technique, in which the atoms are retarded by a set of counterpropagating laser beams with their frequency tuned slightly below that for an atomic resonant absorption. The Doppler shift then ensures that the moving atom has the sisyphean task of always having to climb up a potential hill and hence get retarded to a near-zero speed. This is then followed by a *forced evaporative cooling* in which the more-than-average energetic atoms are allowed to escape the magnetic trap at the edges, leaving the tardier atoms to thermalize to a lower temperature. The evaporation is ingeniously *forced* by an rf magnetic field that flips the spins of the

energetic atoms near the edge. This instantly inverts the potential well, thus facilitating escape. These techniques, developed and perfected over the years building on the work of several research groups, enabled the researchers to create finally the extreme condition of phase space density $n\lambda_T^3 = 2.621$ required for BEC. Here n is the number density and $\lambda_T = h/(2\pi m k_B T)^{1/2}$ is the thermal de Broglie wavelength of the condensing atoms.

Now, the idea of Bose–Einstein condensation is by itself not new, having been predicted by Einstein in 1925 for ^{4}He, basing on the then new quantum Bose statistics for particles with integral spin, such as photons, proposed by Satyendra Nath Bose[2]. Unlike their half-integral 'exclusive' cousins, the fermions (such as electrons or ^{3}He), bosons are gregarious, and arbitrarily large number of them are allowed (in fact, are *encouraged* to) occupy a given single-particle state. At a sufficiently low (high) temperature (density) this creates an overpopulation crisis and a macroscopic (finite fraction of the total) number condenses into the lowest single-particle state. This, of course, happens only for permanent bosons with a fixed given number (e.g. ^{4}He) and not for photons, say, where the number keeps diminishing as the temperature is lowered and hence no BEC. At this phase-space density, the de Broglie wavelength is comparable to the mean interparticle spacing (overlapping wavefunctions), and the quantum-mechanical indistinguishability of identical particles asserts itself by making the condensate behave as a single coherent entity. Stable BEC is known to exist in liquid ^{4}He below 2.2 K, where it is implicated in superfluidity. It has been achieved transiently in a gas of excitons, electron-holes ($e^- - e^+$) bound pairs created optically in a semiconductor like cuprous oxide[3]. Spin-polarized hydrogen (H↓) has been for the last 15 years a strong candidate: it remains gaseous down to absolute zero of temperature[4]. Then why so much excitement about BEC in ^{87}Rb, one may ask. Of course, the threshold phase-space density for BEC is easier to obtain for the lighter atoms. But, the purely quantum-statistical effects are corrupted by the strongly interacting nature of these dense systems. By comparison, for the dilute ^{87}Rb gas in question, the mean interparticle spacing ($\sim 10^{-4}$ cm) >> the scattering length ($\sim 10^{-6}$ cm) and hence the near-ideal Bose gas condition prevails. (The magnetically trapped gas is metastable against crystallization at nanokelvin temperatures). Also, ^{87}Rb with conveniently accessible electronic transitions is manipulable, even its interactions are optically tunable. One can probe the entire quantum phase diagram – dilute gaseous BEC, dense liquid BEC, superfluidity, quantum solid and possibly superfluid solid! Also, the kinetics of the Bose–Einstein condensation itself[1]. Besides, compared to the aristocratic quantum fluids, e.g. ^{4}He, the rubidium-87 (an alkali) is really ordinary!

In what sense is BEC *coherent matter*? This is best illustrated by its possible interaction with light, e.g. photoassociation[5]. For a condensate of N atoms, the optical transition-dipole will be $\sqrt{N}$ times that for a single atom even if the condensate size is less than the wavelength of light. Coherent matter analogue of optical laser is also being speculated upon!

One could envisage several other basic studies – Anderson localization (and confinement) of BEC by random potential created by an optical speckle pattern simulating quenched disorder. One could also examine the fundamental question of the effect of frictional (γ) decoherence on BEC – one may not have any BEC at all for $\gamma > (\hbar/m)\, n^{2/3}$ even at the absolute zero of temperature. The friction γ can be tuned optically, or by dilution with noncondensing (fermionic) atoms. One expects a BEC to have a negative temperature coefficient of expansion. And so on.

One may conclude by saying that if phase and coherence are to dominate our thinking in the years to come, then the coherent matter (BEC) may well be a laboratory of choice.

SCIENTIFIC CORRESPONDENCE

'Swiss' strain of rats?

The strain of rats used in the study (A. K. Mitra *et al.*, *Curr. Sci.*, 1995, **68**, 1050–1053) is given as 'Swiss strain'. As one representing an organization concerned with laboratory animals maintenance and supply, I can authentically say that 'Swiss' strain of rats does not exist. Most of the laboratory rats currently available for biomedical research have originated from the brown Norway rat – *Rattus norvegicus* and some common strains originating from this are Wistar, Holtzman, CFY and Sprague–Dawley to mention a few. But most of the mice strains have a 'Swiss' origin and many random-bred albino mice available in various laboratories are loosely termed as 'Swiss' strain. Obviously there is a mistake somewhere and it is better that the authors clarify this from their 'aunthentic breeders'.

Regeneration of *Aegle marmelos* (L.) Corr. plants *in vitro* from callus cultures of embryonic tissues

Aegle marmelos is a medium, spreading deciduous spiny tree belonging to the family Rutaceae. It is supposed to be originated in the Indo-Burma subcontinent[1]. Various parts, including fruits, possess medicinal properties and have been extensively used in ayurvedic and folk medicine[2,3]. Since *A. marmelos* is an outbreeding crop and cross-pollination leads to highly heterozygous population[4], propagation through seeds is not encouraged. Singh[5] was first to culture *A. marmelos* but regeneration of plants from nucellar tissue was not possible. Arya *et al.*[4] described callus formation and some organogenesis from cotyledon and hypocotyl cultures. Recently, regeneration of multiple shoots through organogenesis was achieved from seedling leaves[6,7], nucellus[8] and cotyledons[9]. This communication presents high-frequency plant regeneration system using callus cultures from zygotic embryos of *A. marmelos*.

Mature seeds from ripe fruits and immature seeds from unripe green fruits were collected and surface-sterilized with 0.1% $HgCl_2$. Seeds were decoated and embryo axes excluding cotyledons were excised and cultured. All cultures were maintained in a growth room under 16 h photoperiod at 26°C. All media were solidified with 7 g/l agar (BDH, high gel strength) and media pH values were adjusted to 5.7 ± 0.1 prior to autoclaving. The basic culture medium was Murashige and Skoog (MS) salts[10] variously supplemented with naphthalene acetic acid (NAA), 2,4-D, IAA, IBA, BA and kinetin. Different concentrations of auxins in the range of 2.5–10 µM were used for callus induction. Plant regeneration was achieved by transferring pieces of callus tissue (fresh weight 100–150 mg) on to the MS medium with different combinations of auxins and cytokinins. Rooting was induced in IBA supplemented (5 µM) MS medium. After rooting, the leafy shoots were washed and transferred to pots containing soil mixed with compost (2:1).

Different concentrations 2.5–10 µM of IAA, NAA and 2,4-D were tried to induce callus and it was observed that 2,4-D in general was more efficient for the induction of callus and induced as much as 80% callus from both mature and immature embryo axes at a concentration of 10 µM. However, addition of a lower concentration (0.5 µM) of BA together with 10 µM 2,4-D induced 100% callus formation in all explants obtained from mature and immature seeds. The 6-week-old hard, green and compact irregularly shaped calli (Figure 1 *a*) induced on 10 µM 2,4-D and 0.5 µM BA were used to study morphogenesis. Such calli obtained from each explant were cut into small pieces (100–150 mg fresh weight) and were transferred to fresh medium. Both BA and kinetin at various concentrations were capable of inducing differentiation from undifferentiated calli (Table 1). Of the two cytokinins, kinetin was better than BA and of the auxins IAA were more efficient than NAA. Thus, the best results for shoot formation were obtained using kinetin at 5–10 µM and IAA at 0.5 µM. In all cases both mature- and immature-embryo-axes-derived calli were capable of producing multiple shoots. However, regeneration frequency and number of shoots per callus were much higher than mature embryo axes.

Proliferating shoots attained a height of 2–3 cm within 8 weeks of culture (Figure 1 *b*). The regenerated shoots were transferred to previously established rooting medium (MS + 5 µM IBA)[9] for adventitious root induction. The rooted shoots reached up to 62% within 4–5 weeks of culture. Regenerated shoots were transferred to pots containing soil mixed with compost. During the first one week, the potted plantlets were covered with glass

5.0	0.5	58.9	30.9 ± 1.8	40.1	14.2 ± 2.6
10.0	0.5	64.0	30.3 ± 3.0	36.0	14.8 ± 2.1
25.0	0.5	64.2	28.0 ± 2.9	37.2	11.4 ± 1.9

beakers to provide high humidity. Transplantation success was 55%. Plantlets were subsequently transferred to larger pots (Figure 1 *c*) and gradually acclimatized to outdoor conditions.

The results presented here indicate that *in vitro* regeneration of complete plantlets is possible using callus cultures from embryo axes of *A. marmelos*. The physiological state of the explant plays an important role in the regeneration of plants. Both immature and mature embryo-axes-derived calli were capable of producing plants. However, while the regeneration frequency of immature-embryo-derived calli was 34.4–94.2%, the morphogenetic capacity of the mature-embryo-axes-derived calli was lower (25.6–52.5%). The immature embryos are known to be a good source for initiating callus which possesses high regenerative capacity, as has been shown in peach[11], oak and linden[12]. The procedure described here may be suited to use in transformation studies and for mass propagation of *A. marmelos* if the frequency of off-types is low.

In vitro axillary bud break and multiple shoot production in *Acacia auriculiformis* by tissue culture technique

Acacia auriculiformis A Cunn. Ex. Benth is a species native to Australia, Indonesia and Papua New Guinea. It has been an important exotic in many tropical countries for more than half a century. The species is currently planted for paper pulp industry[1], fuel wood, erosion control, shade and ornamental purposes. It is a leguminous, nitrogen-fixing tree of the subfamily Mimosoideae. Mass multiplication of elite and rare trees is of paramount importance[2]. Though *Acacia auriculiformis* is propagated by seeds, poor seed germination, around 20–25% has been recorded[3]. So, research is needed on large-scale multiplication of elite clones. The tissue culture technique can be used as a promising tool in overcoming this problem. Much less work has been carried out in this regard in Acacia species. A few workers have reported plantlet formation at seedling level through cotyledonous callus, shoot tip callus and axillary buds[4–6]. But no work has been reported on plant regeneration in mature Acacia trees. The present study reports on *in vitro* development of nodal shoots from axillary buds and multiplication of these nodal shoots into plantlets from 20-year-old Acacia trees.

Small tender branches (10–15 cm length, with 6–7 nodal segments) with

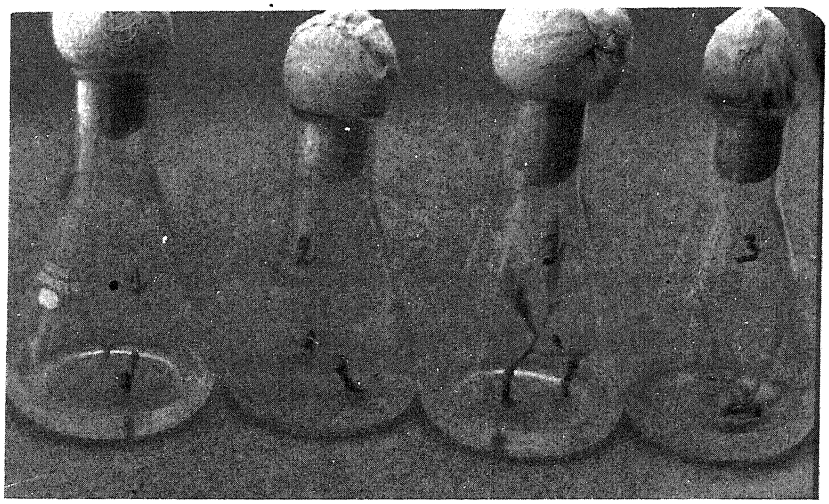

Figure 1. Development of shoots from nodal segments.

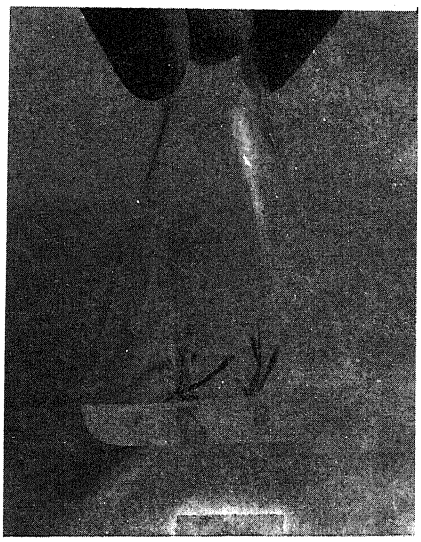

Figure 2. Development of multiple shoots from nodal segment shoot.

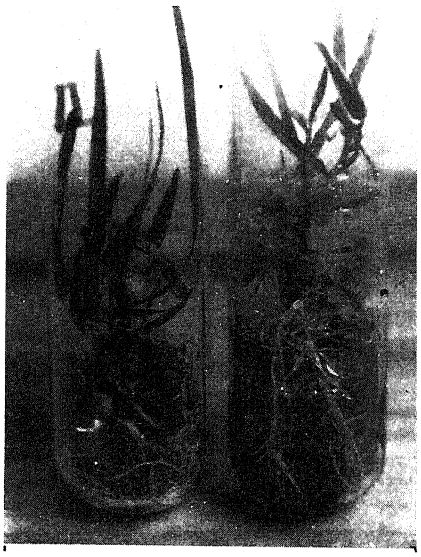

Figure 3. Development of roots in *A. auriculiformis*.

buds of *Acacia auriculiformis* were cut from the mother plant and washed thoroughly under running tap water for 1–2 h. Then they were treated with Bavistin (W/P) 0.5% for 1 h and washed thoroughly in single-distilled water 2–3 times. These branches were surface-sterilized aseptically with 0.1% mercuric chloride for 8–10 min and then thoroughly washed with sterilized water 4–5 times. The leaves were removed and the branches cut into small nodal segments. These segments were placed on modified Murashige and Skoog medium[7] with 0.2% gelrite/0.8% agar supplemented with BAP (1 and 2 μM per litre) and NAA (1 and 2 μM per litre), and 2% sucrose; the medium was adjusted to 5.8 pH and autoclaved for 15 min at 15 lb/in^2 and a temperature of 120°C. Then these flasks were incubated under 16 h light and 8 h dark period at a temperature of 26 ± 3°C. After one month the axillary buds sprouted and developed into shootlets (Figure 1). These shootlets were excised from the main explant and transferred to the multiplication medium containing MS medium with high phosphate (NaH_2PO_4 340 mg/l), supplemented with BAP (5.0 and 7.5 μM/l) and NAA (1 and 2 μM/l), 2% sucrose and 0.2% gelrite. Twenty days after inoculation, 5–7 small shoots per culture arose from the base (Figure 2). Research is in progress to achieve more multiple shoots by altering the cytokinin and auxin ratio. Rooting was achieved in MS medium with charcoal (0.1%) and MS medium with 0.5 mg IBA and charcoal at 0.1% (Figure 3).

Effect of foetal exposure to low-dose X-rays on the postnatal growth of mouse

Even though the late organogenesis period in mammals is considered to be the most sensitive one to radiation-induced developmental anomalies, a recent study from our laboratory has shown that the early foetal period, day 14.5 post-coitus (p.c.), is also susceptible to γ-ray-induced foetal growth retardation and microcephaly in mouse

Table 1. Observations on postnatal development of mice exposed to 0.05 Gy of X-rays at day 14.5 post-coitus

Observations	Treatment	Age of offspring (week)						
		0	1	2	3	4	5	6
Number of offsprints	C	122	121	120	119	117	115	114
	E	98	96	95	94	92	88	87
Growth-retarded offsprings(%)	C	1.64(2)	1.65(2)	2.50(3)	3.36(4)	3.42(4)	3.48(4)	3.51(4)
	E	4.08(4)	4.17(4)	7.37(7)	10.64(10)*	11.96(11)*	11.36(10)	8.04(7)
Body weight (mean ± SE, g)	C	1.67 ± 0.014	4.76 ± 0.054	7.27 ± 0.081	11.59 ± 0.159	17.57 ± 0.367	24.43 ± 0.273	28.05 ± 0.303
	E	1.64 ± 0.018	4.62 ± 0.059	7.09 ± 0.125	10.71 ±0.215	15.68 ± 0.486	22.23 ± 0.489[c]	27.15 ± 0.446
Body weight (mean ± SE, mm)	C	32.1 ± 0.115	46.78 ± 0.235	54.91 ± 0.227	68.06 ± 0.366	79.65 ± 0.447	87.83 ± 0.366	91.64 ± 0.417
	E	31.88 ± 0.135	46.19 ± 0.317	54.79 ± 0.417	64.68 ± 0.670	71.62 ± 0.789[c]	83.95 ± 0.949[b]24.	89.89 ± 0.814
Head length (mean ±SE, mm	C	8.73 ± 0.056	13.83 ± 0.091	15.86 ± 0.103	20.85 ± 0.146	22.38 ± 0.160	12 ± 0.115	24.70 ± 0.125

Note: Figures in parentheses are the actual numbers.
[†]C: Sham-irradiated animals, number of mothers 15.
E: Exposed to 0.05 Gy X-rays, number of mothers 12.

Difference from respective controls (C): [a]$p < 0.05$, [b]$p < 0.01$, [c]$p < 0.05$, (Mann–Whitney test) *$p < 0.05$ (Fisher's exact test)

(unpublished observation). Therefore a study was done to find out the effects of low-dose X-rays at day 14.5 p.c. on the postnatal growth of mouse.

Virgin female and male Swiss mice (8–10 weeks old) from an inbred colony, maintained under conditions of controlled temperature (22 ± 3°C) and light (10 h light, 14 h dark), were mated overnight. The day the vaginal plug was observed was considered as day 0 of pregnancy. Pregnant females were exposed to 0.05 Gy of X-rays on day 14.5 of gestation, as described earlier[1,2]. One group of animals was sham-irradiated to serve as control. The experimental and control animals were left to parturate. The offsprings were observed for changes in body weight, body length, head length, head width, tail length and post-natal mortality from day 0 (the day of birth) up to 6 weeks post-partum (p.p.). Sex ratio was determined at birth. The data were evaluated by the non-parametric Mann–Whitney *U*-test and Fisher's exact test, using GraphPad In-Stat software; p values < 0.05 were considered statistically significant.

A total of 220 offsprings from 27 mothers were examined. The litter size, sex ratio and postnatal mortality were not affected by irradiation. The number of growth-retarded offsprings was significantly ($p < 0.05$) higher than control at 3 and 4 weeks, but the difference became nonsignificant by 5 weeks (Table 1).

Irradiation did not affect the birth weight of the offsprings. The body weight showed significantly ($p < 0.01$, $p < 0.001$) lower than control values from 3 to 5 weeks (Table 1). A similar response was observed for body length also. The head length showed significantly ($p < 0.001$, $p < 0.05$) lower values at 4 and 5 weeks of age. However, reduction in head width was apparent from 2 to 5 weeks. All the parameters recovered by 6 weeks. The tail length was significantly ($p < 0.05$) lower than control at 2 weeks, with further reduction at later postnatal ages, with no recovery (Table 1).

Based on the early data, it was concluded that the killing of foetuses requires high doses of radiation[3]. However, more recent *in vitro* and *in vivo* studies have shown that relatively small doses (5–10 cGy) can cause embryonic and foetal mortality[4]. The present data did not show any significant increase in postnatal mortality.

A decrease in weight of rats and mice has been reported after exposure to higher doses of radiation[5,6]. Studies with very low doses are few. Hande *et al.*[2] observed that 5 cGy of X-rays given at the major organogenesis period induced a significant reduction in postnatal weight. The present study shows that such an effect can be induced by low-dose X-rays when exposed at the early foetal period also, but this effect is temporary and complete recovery is effected by the time the animals reach adulthood. There are no comparable published reports on postnatal body length and head size measurements, though our own study has shown a reduction in the head size of 18-day-old foetuses after exposure to ~1 cGy X-rays during the late organogenesis period[1]. Diminished head size has been reported to be a readily detectable effect in prenatally exposed Japanese A-bomb victims[7].

Tail growth seems to be more sensitive to exposure at this stage than the other parameters. There are no comparable studies on the effect of low-dose *in utero* exposures during early foetal period on postnatal tail measurements. However, stunting of skeletal growth has been reported by several investigators after high doses during 14–18 days p.c. in rats and mice[8,9].

Recently, Uma Devi *et al.*[10] have reported that doses below 25 cGy of γ rays produced no marked foetal mortality or growth retardation when exposed on day 11.5 p.c., which is a more radiosensitive stage than day 14.5 p.c. in mouse development. However, the present results suggest that in the case of X-rays even doses as low as 5 cGy on day 14.5 p.c. can lead to growth retardation. Even lower doses (~1 cGy) of X-rays during the organogenesis period have been found to produce growth retardation in mouse foetus[1, 11]. These results strengthen our earlier assumption that at low doses X-rays may be more effective in influencing mouse development than γ-radiation[10].

The quest for quantum gravity

Gary K. Au

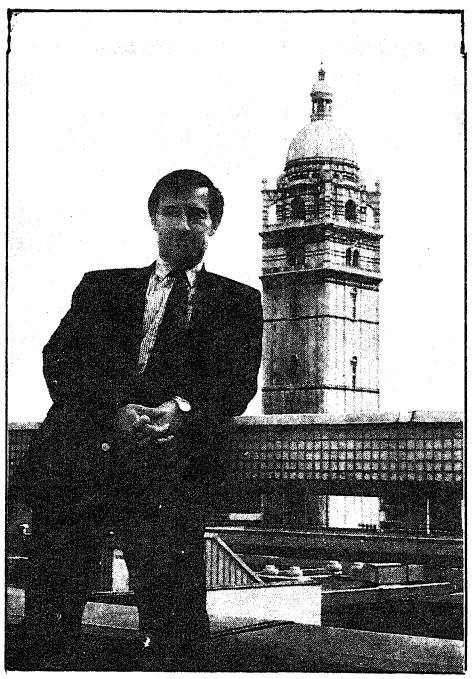
One of the greatest challenges facing theoretical physics lies in reconciling Einstein's classical theory of gravity – general relativity – with quantum field theory. Although both theories have been experimentally supported in their respective regimes, they seem mutually incompatible. This article summarizes the current status of the superstring approach to the problem, the status of the Ashtekar programme, and addresses the problem of time in quantum gravity. It contains interviews with Abhay Ashtekar, Chris Isham and Edward Witten.

'It is very important that we do not all follow the same fashion ... It's necessary to increase the amount of variety ... and the only way to do this is to implore you few guys to take a risk with your lives that you will not be heard of again, and go off in the wild blue yonder to see if you can figure it out.'

Richard Feynman (1965), Nobel prize in physics award address

The road to quantum gravity (QG) has had a long and winding history. Although we are unlikely to see the day of a direct test of quantum gravity, such a theory is needed to describe the early stages of the Big Bang. Around this time the universe would be about the size of the Planck volume. Quantum gravity effects, ignored in particle physics because of their weakness, would have a major influence on the subsequent evolution of the universe. Also a QG theory is desperately needed to make the standard model a consistent physical framework.

Why are we spending so much time on such a lofty goal? Richard Feynman commented on the aims of science: 'If you expect science to give you all the answers to the wonderful questions about what we are, where we are going, and what the meaning of the universe is, then I think you could easily become disillusioned and look for a mystic answer to these problems.'



'The way I think of what we're doing is, we're exploring – we're trying to find out as much as we can about the world. People say to me, "Are you looking for the ultimate laws of physics?" No, I'm not. If it turns out there is a simple, ultimate law which explains everything, so be it; that would be very nice to discover. If it turns out it's like an onion, with millions of layers, and we're sick and tired of looking at the layers, then that's the way it is. But whatever way it comes out, it's nature, and she's going to come out the way she is! Therefore, when we go to investigate it we shouldn't predecide what it is we're going to find, except to try and find out more.' [*No Ordinary Genius – The Illustrated Richard Feynman*, Christopher Sykes, W. W. Norton, New York, 1994, p. 251]

The problem of time[1–5]

A key question which faces any approach to QG is the 'problem of time': how does a time variable, with its special properties in relation to the probability interpretation of quantum mechanics (QM), emerge? A related topic which has been attracting increasing attention, especially in the context of 'quantum cosmology' is the 'consistent-histories' approach to quantum theory. One of the most exciting features of the programme is the possibility of changing quantum theory itself in the context of the physics of the early Universe and the way in which it came into being.

The basic problem lies in the incompatible way in which the concept of time is treated in QM and general relativity (GR). One of the main researchers studying this deep problem is Chris Isham at Imperial College, London.

Chris Isham

In QM time evolution is described by the Schrödinger equation. However, the time parameter that comes into the equation is a background parameter. This is unlike other quantities which can be represented by Hermitian operators. So from the very beginning QM attaches a special significance to the idea of time. It is like the steady ticking of an external clock hand in the background, which we have no control over. Can we physically measure this quantity? Is it possible to reformulate QM so that the idea of a background time does not appear? According to Chris: 'It is possible to do this in a formal sort of way but it does not really get you far. The basic fact is that conventional quantum theory presupposes an external time whose ontological (see note 1) status is the same as it possesses in classical Newtonian physics. In relativistic quantum theories this is generalised to become a background Minkowskian spacetime – so it is the causal structure that is fixed. There are some intriguing mathematical theorems (going back to Pauli I believe) showing that you cannot construct quantum clock that would exactly measure this background time. In that sense, some people might want to consider "time" as part of the external classical realm that Bohr postulated was necessary to interpret the equations of quantum theory. I have always suspected that Bohr himself would have regarded the subject of "quantum gravity" as a non starter!'

Why does time deserve a special status in QM? Well, if you could raise it to the status of an operator T then its conjugate variable would be the energy H. These would need to satisfy the commutation relations $[T,H] = i\hbar$. Mathematically, it can be shown that it is impossible to have a pair of Hermitian operators satisfying these conditions, in which one of them has only positive eigenvalues. This relates back to Chris' remark about the problem of quantum clocks. In other words, we have the problem of a system with negative energy.

In QM, measurements of observables are taken at fixed times, a complete set of commuting operators (defining the maximum information you can obtain from a system) is required at fixed times, and the scalar product on the Hilbert space of states has to be conserved under time evolution of the Schrödinger equation. Time plays a foundational role in the technical and conceptual aspects of quantum theory. However, it is an idea grounded in the world of continuum mathematics. If it breaks down at the Planck scale, where some believe a discrete structure will emerge, what are we left with? Indeed, how much of QM will hold?

According to John Wheeler: 'The word "time" was not handed down from heaven as a gift from on high; the idea of time is a word invented by man, and if it has puzzlements connected with it, whose fault is it? It is our fault for having invented and used the word (see note 2). Taking this into mind, could we redefine time so that it reduces to the familiar clock ticking concept in some classical limit?'

Chris Isham is very sympathetic to this view: 'I would bet strongly that whatever the "final" theory of quantum gravity will be, we shall see our standard notion of time emerging only in some semiclassical sense.'

The role of time in relativity is very different to its role in QM. Relativity treats time at par with the other three spatial variables. Indeed, time and space are unified into a four dimensional spacetime manifold.

On this matter Chris explains: 'The notion of a single, four-dimensional, "spacetime" (rather than separated three-dimensional space plus one-dimensional time) first appears in special relativity (SR) because of Einstein's realization that any absolute split of 3+1 is observer-dependent. General relativity works with a curved version of the flat space–time of special relativity.'

'In both special and general relativity a "moment of time" corresponds to a single space-like hypersurface in the space–time. Time itself appears as the parameter that labels the elements of a one-parameter foliation (see note 3) of space-time by such surfaces. In the case of special relativity you restrict your attention to the case where the space-like surfaces are (i) hyperplanes, which are (ii) mapped into each other by actions of the Poincaré group. The main challenge in quantum theory is to show that all such admissible families give the same physical answers.'

'The situation in general relativity is more complex. One says that a hypersurface is space-like if the vectors tangent to each point of the surface are space-like. The idea here is that the Lorentzian metric on spacetime induces on each tangent space a copy of the Minkowski metric of special relativity, and it is with respect to this latter metric that the tangent vector has to be space-like. Put slightly less rigourously, a hypersurface is space-like if any "infinitesimal" transformation in the surface always points in a space-like direction.' (Figure 1)

The crucial point here is that the problems encountered when incorporating SR into QM can be overcome. When we try to add GR to the QM picture, the intricacies are much more difficult to handle.

With a *curved* spacetime equipped with a Lorentzian metric tensor, how many ways are there to foliate spacetime as a one parameter family of space-like surfaces? Chris continues: 'In some spacetimes there is a topological obstruction to performing *any* global foliations. But if such foliations are possible then there will be an uncountable number of them, each corresponding (in general relativity) to an allowed definition of time.' In other words, unlike in SR, we cannot define a unique time according to which we evolve a system. This is the main difference between the concept of time in special and in (classical) general relativity. It is an important aspect to the problem of time in QG. On the one hand, we have a Hamiltonian formulation of QM for privileged SR space-like surfaces. On the other we have general covariance in GR, which states that no one set of

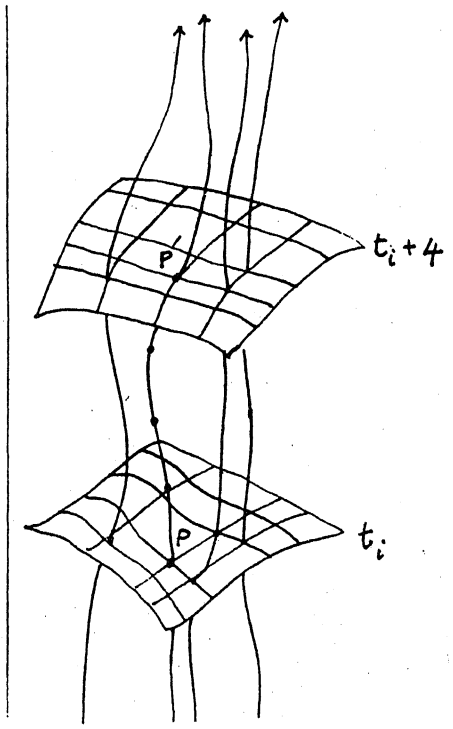

Figure 1. Foliating spacetime into a one-parameter family of space-like hypersurfaces: In Newtonian mechanics, a given moment of time has the same meaning for all observers. Time is absolute. In SR, this notion is somewhat ambiguous because of the nonuniversality of simultaneity. However, once an inertial frame is specified, the notion becomes more precise. Unless spacetime is flat, there are no global inertial frames in GR. So 'a moment of time' in GR is ambiguous. However, a more general concept replaces it; the notion of 'a given space-like hypersurface'. It is possible to 'slice up' or foliate spacetime into a one-parameter family of 3D space-like surfaces, filling out all of spacetime. At each event on a surface, there is a local Lorentz frame whose surface of simultaneity coincides locally with the hypersurface. Lorentz frames at various events do not mesh to form a global inertial frame, but their simultaneity surfaces mesh to form the actual space-like hypersurface. This is a picture of two space-like hypersurfaces through events P and P' which occur at different times. World lines of observers cross these surfaces orthogonally, and are labelled by (x_1, x_2, x_3), $x_0 = t_i + \tau$, where τ is the proper time measured along the worldline. Note that the third coordinate x_3 is suppressed in the diagram. Arbitrary coordinate grids defining x_1 and x_2 are drawn on the hypersurfaces. At the point of crossing a hypersurface, the proper time (defined by an observer's wristwatch) reads the same as other observers' watches. Such a surface defines a notion of 'simultaneity'. Another surface of simultaneity through the event P may have a different slope or curvature (defining different local Lorentz frame). This second surface is defined by another set of observers with their own wristwatches, and their own proper time readings. It is also possible to push the hypersurface ahead in time at different rates in different places, so long as the hypersurface stays spacelike. This idea of a 'many-fingered' time is GR's dramatic new contribution to our understanding of time. See, for example, *Gravitation*, C. Misner, K. Thorne and J. Wheeler, W.H. Freeman and Co., 1973.

space-like surfaces has privilege as a reference system over others.

When we get to Planck scale physics, spacetime geometry could be subject to Heisenberg's uncertainty principle, varying about quantum-mechanically. In other words, the GR metric tensor $g_{\mu\nu}$ could have fluctuating components! How could one define a light cone and hence a space-like, light-like or time-like separation under such circumstances? Without such a definition, the idea of a space-like surface seems invalid. Perhaps the idea of a spacetime (a continuous manifold of points) does not have physical meaning in the QG regime, where the light cone could be smeared out.

To this Chris says: 'You cannot define a light cone, etc., except in some "background" sense, and this perhaps is the essence of the problem of time in QG: there is no fixed microcausal structure which can be used to construct a relativistic quantum theory in any of the standard ways.'

'However, this does not rule out a priori a continuous manifold: the ideas of causal structure and continuous manifold are in no way synonymous. You can easily have the latter without the former (although I myself am very sympathetic to the idea that the idea of a "continuum spacetime" is not something that will carry across to the "final" QG theory).'

One possibility at the Planck scale is for topology changes in spacetime geometry. Fixing a background topology and differential structure to that of Minkowski space, as is done in quantum field theory, seems to presuppose a lot at the Planck scale.

If we stick with a continuum formulation of QM based on complex numbers, could we be missing out on revealing some sort of a discrete structure at the Planck scale? One can see how a discrete theory could reduce to a continuum one in the large scale limit, but to shed light on a discrete theory while working from the perspective of a continuum one seems difficult to achieve.

Chris has felt this for a long time. One of the many reasons why he is so interested in the new decoherent-histories approach to quantum theory, and is developing his own quantum-logical version, is that the role of the continuum is isolated in a particularly efficient way. In his scheme it is just the space in which the decoherence functionals take their values. He says: 'It is sometimes suggested that near the Planck length a more "combinatorial" approach to physics may be appropriate, and I have some sympathy with this view. I think it would be much easier to think about such schemes within this new approach to quantum theory than in the old Hilbert space one.'

Is superstring theory able to handle this fundamental problem of time in its present perturbative formulation?

Chris replies: 'No. Although it is essential to emphasize that the "problem of time" is not a single problem (or even collection of problems) that applies willy-nilly to any attempt to construct a quantum theory of gravity. It is very approach-dependent and looks very different

in different approaches to quantum gravity. For example, if space and time themselves do "emerge" in some nonperturbative way from superstring theory, then questions concerning the nature of time will look very different from those that arise naturally in, for example, the Wheeler–DeWitt approach to canonical quantum gravity. That is one of the many reasons why it is important to keep trying to find a new nonperturbative way of looking at superstring theory.'

The universe is modelled as a closed system. In its present formulation QM is inadequate for handling such models. After all, how does one define a time external to the universe? How successful have attempts been to define an internal time using, say, matter fields?

'They have been getting better. In a recent paper (see note 4) Karel Kuchar (who is the world expert on this type of thing) has come extremely close. Just how close depends precisely on what one decides one is trying to achieve. From one perspective one could say that he has succeeded in a technical sense, although he would be the first one to agree that his particular definition of time is not too compelling in any fundamental physical sense.'

Karel uses dust particles (see note 5) to fix points in space and identify moments in time. The dust acts like a reference fluid analogous to the old aether idea but with the significant difference that the aether was usually regarded as fixed, i.e. part of the background structure, whereas these dust particles do obey equations of motion. Hence, in a sense they are dynamic, as is the geometry of space–time.

One of the problems of working in QG is the lack of empirical data. One clue comes from the 1992 COBE results. These showed variations in the blackbody microwave background coming from different directions of the sky. These date back to 300,000 years after the Big Bang and are consistent with the inflationary scenario. The observations provide evidence for the idea of quantum fluctuations as the origin of the galaxies. Could they have any implication for the QG regime of 10^{-43} s after the Big Bang?

'Stephen Hawking has claimed that they support the ideas on the very early universe put forward by himself and Jim Hartle. However, the COBE data are currently being cited by a number of people in support of a variety of different views, and it is not clear yet what the outcome will be.'

Consistent histories

An approach which attempts to remove reference to external time in QM is that of consistent histories, pioneered by Griffiths, Omnès, Gell-Mann and Hartle. It generalizes QM via a sum over spacetime histories formulation. The motivation is to describe the QM of closed systems in the context of quantum cosmology. It hopes to shed light on the initial condition of the universe. The basic idea in this scheme is a QM history. The scheme, therefore, de-emphasizes the notion of a QM event at a single moment in time. It makes no reference to external observers, classical measurement apparatus, or wave function collapse (reduction of the state vector). However, it is possible to recover Bohr's formulation of QM under suitable conditions. Chris Isham is working on a version of this idea.

'Most work on this approach has been applied to standard quantum theory, not quantum gravity. To bring in quantum gravity, Hartle has discussed the possibility of using solutions of the Wheeler–DeWitt equation in the context of Euclidean path integrals. I myself am working on this general problem but from a completely different tack. I and my colleagues have been studying consistent histories using a new type of "quantum logic" of propositions about generalized spacetime structures. But the general idea in this formalism still holds: i.e. properties can only be ascribed to a "history" only when it is part of a consistent set. Typically, this requires deliberately loosing information by coarse-graining. One's expectation is that "time" is something of this sort: i.e. it is really only part of a semiclassical world that will "fade away" if one probes too closely.'

The scheme's main goal is to assign probabilities to families of histories in a closed system. A history is defined to be a sequence of QM events at a succession of times. QM events are tested for using projection operators which satisfy the properties of exhaustivity and mutual exclusiveness. Two types of projections are defined: fine-grained and coarse-grained ones.

The main problem in the formalism is interference. Interference between different histories forbids assignment of probabilities since probabilities have to satisfy certain axioms to be meaningful. They must be nonnegative, normalized, and they must sum to unity. Complex probability amplitudes can be assigned to histories, but a probability is defined as the modulus squared of an amplitude. This operation introduces cross terms which violate the probability axioms.

To handle this problem 'consistency conditions' are introduced. These determine sets of histories which negligibly interfere, and to which probabilities may be assigned. These conditions can be combined into a decoherence functional, which is the main calculational tool of the QM of history. It must satisfy the properties of hermiticity, positivity, normalization and the superposition principle. The functional is computed using standard quantum mechanics. Griffiths, Omnès, Hartle and Gell-Mann's contribution is the new probability interpretation. Here the notion of 'superposition' does not mean quite the same as it does in the standard way of superposing wave-functions. It is more a question that the decoherence functional must be additive with respect to a disjoint sum of histories.

In order to decouple interfering histories by coarse graining, we require the idea of decoherence. Consistent (decoherent) histories are then sets which obey the consistency conditions. Consistency is a property of families of histories, of which there may be many.

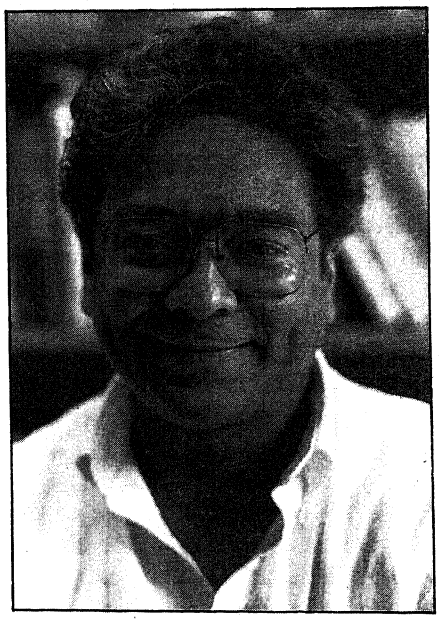
But what is the mechanism of decoherence? It has been postulated (see note 6) that the environment decoheres by acting like a sink, by draining off coherence – similar to a piece of blotting paper soaking up excess ink. But if the system is a closed QM universe, how do you define an environment? What other methods could there be to decohere closed systems?

To this problem Chris remarks: 'The mechanism for decoherence in a truly closed universe is, to my mind, still rather problematic. There have been attempts, for example, to identify part of the gravitational-field complex as the environment, and part as "really quantum" freedom in this environment. But I am doubtful whether this is really a universal notion. The examples I have seen have all been for very simplified models.'

In a closed QM universe, would it be possible to use black holes as decoherence devices? When matter goes into a black hole, the only properties of the hole which are observable via its distant electromagnetic and gravity fields are mass, charge and angular momentum. All other information is lost. Would this loss include 'interference' information between histories?

Unfortunately, Chris says: 'One could do that when studying quantum theory in a fixed background, since then one could consider a background containing black holes. However, this is not too meaningful a priori in a full theory of quantum gravity itself since the black holes will also have to be quantized in some sense.'

Jim Hartle made the important observation that one can talk about 'generalized histories' in QG in which the word 'history' need not presuppose a conventional type of time parameter. According to Chris: 'The basic entity in the scheme is a "possible universe". A simple, but informative example would be a Lorentzian geometry that is not globally hyperbolic. Such a spacetime does not admit a global foliation by space-like surfaces, and hence there is no global time parameter. Nevertheless, it is a viable classical possibility since time still makes sense locally (i.e. the local proper time along a world line). This was one of the original motivating examples suggested by Hartle.'



'However, my own interest in this scheme is when the basic entity is something more basic that does not necessarily include any manifest time-like features at all. This would be in line with the general idea that time appears only in some semiclassical limit. Of course, this leaves quite open what types of object one would actually use as "possible universes" since this depends entirely on the actual theory that is to be developed (the decoherent-histories approach is not a *theory per se*, it is more a *theoretical framework* in which new types of theory can be developed). For example, I am currently thinking about the possibility of constructing such a theory in which the basic entities are simply point-set topologies.'

'In theories of this generalized type, Hilbert spaces do not appear as basic mathematical structures in the same way as they do in normal quantum theory; indeed, in the scheme that I am developing, the basic mathematical structure is much closer to that of quantum logic (i.e. an algebraic approach) than it is to Hilbert space methodology. On the other hand, in any theory in which time could be shown to 'emerge' in some coarse-grained limit I would expect the usual Hilbert space structure to emerge too at the same level. However, as no one has yet written down an explicit example of this type, it is hard to be more specific!'

The Ashtekar programme[6–21]

People have approached the QG problem from many different directions, some more successful than others. Most attempts suffer from seemingly insurmountable problems. A short list of avenues includes higher-derivative Lagrangians, twisters, induced gravity, Kaluza-Klein theories, Euclidean quantum gravity, covariant perturbation theory, discrete gravity, nonlinear quantum mechanics, spin networks, asymptotic quantization, quantum cosmology, the decoherent histories just covered, quantum field theory in curved spacetime, superstrings, and canonical gravity. The Ashtekar programme belongs to the last category.

Abhay Ashtekar is at the Centre for Gravitational Physics and Geometry, Pennsylvania. Although his programme involves esoteric mathematics, some of its key features can be described qualitatively.

Abhay Ashtekar

An obvious question that people might ask about QG research is: Why are we spending so much time and effort trying to obtain a theory which is most probably untestable, and which will not have any practical application? Abhay doesn't quite agree with the assumptions here. He says: 'We are seeking a *physical* theory and, therefore, it will definitely have testable predictions. The initial tests will be probably indirect. For example, we have this great puzzle for over 50 years: quantum field theory provides incredibly accurate predictions in particle physics, yet it is, in a sense, only a set of calculational recipes, without a coherent, complete mathematical framework. Again, the recipes work incredibly well and should be taken seriously. But surely, they are incomplete in some essential way. The ultraviolet divergences arise largely because we assume that space–time is a continuum at all scales. If a quantum theory of gravity provides an alternate picture of space–time, it should lead to an alternate way of doing quantum field theories which is coherent and mathematically consistent. So, in a sense, the vast experimental data we have accumulated in particle physics could provide tests of the space-time models that come from quantum gravity.

'Furthermore, it is possible that quantum gravity will also lead to "practical applications". Recall that when Einstein discovered special relativity, most people thought that it was an esoteric theory which would have little impact, if any, on daily life. However, the theory then led to $E = mc^2$, which has had profound ramifications on the entire world order of this century. Quantum gravity will also change our understanding of space and time radically and may, therefore, have some really deep practical implications. I would hope that they would be more peaceful in nature!'

'But of course we do not have the faintest clue of such applications today and, as you indicate, it is beyond today's technology to test the quantum gravity effects *directly*. The primary motivation is really conceptual. Again, there is a similarity with special relativity. Just as the primary motivation for special relativity came from the incompatibility between Newtonian mechanics and Maxwell's electrodynamics, the two pillars of the 19th century physics, the primary motivation for quantum gravity comes from the tension between general relativity and quantum mechanics. There should be a deeper theory which unifies the principles of both in such a way that these two theories emerge in suitable approximations. That is the theory that workers in quantum gravity are trying to construct.'

Abhay's programme was inspired by the failure to find a renormalizable perturbative theory of quantum GR (QGR). What this is, and what would have happened if this failed programme had been successful?

He explains in depth: 'Perturbation theory assumes that answers to physical questions can be obtained by a method of successive approximations, generally expressed in terms of a power series in the coupling constant. We routinely use such approximations already in quantum mechanics. In quantum field theory, however, there is a key difference. Whereas in quantum mechanics, we know from general principles that the exact answer exists and is finite, and perturbative techniques are used only as a computational tool, in realistic quantum field theories in four dimensions, we do not have an assurance that there is an underlying well-defined theory; the perturbation series itself is being used to define the theory. To make matters worse, each term in the perturbative expansion diverges because one is allowing virtual processes of arbitrarily large momenta. In renormalizable theories, the infinities that arise are of a special nature; they can be absorbed into a finite number of parameters associated with the theory such as charges, masses and coupling constants. Once these parameters are renormalized by the appropriate infinite factors, all individual terms in the perturbative expansion become finite. The actual renormalized parameters can be determined by a finite number of experiments. Further experiments then provide tests of the theory. In a nonrenormalizable theory, this cannot be achieved and, therefore, the perturbation expansion has no predictive power.'

'Another way of stating the difference is that, in a renormalizable theory, predictions for phenomena at a given length scale are insensitive to what is happening at much smaller scales. So, for example, since QED is renormalizable, its predictions for processes at, say, a GeV scale are insensitive to all the goings on at the Planck scale (10^{19} GeV). In nonrenormalizable theories, this is not the case; the predictions for one length scale *are* sensitive to what is happening at much smaller, scales. It is thus harder to extract the physical content.'

'If perturbative general relativity had turned out to be renormalizable, on the one hand, life would have been simple. One could have calculated scattering cross-sections in gravity using familiar methods. On the conceptual side, however, at least some people, including me, would have been disappointed. It would have meant that most of physics is insensitive to the "true" small scale structure of space–time and hence it would have been harder to "probe" this structure. I have expressed my unease with the current status of quantum field theory. It is the nonrenormalizability of gravity that forces us to seek the true microstructure of space–time and holds clues for obtaining something which goes beyond (the calculational recipes of) quantum field theory.'

Perturbation theories assume that spacetime is a continuum at all scales. Could this be a reason why they fail for QG, where the short distance behaviour of spacetime might not be a continuum? An analogy has been made that spacetime is a 'foam' of sorts at Planck scales, subject to Heisenberg's uncertainty principle.

'That's right! The key infinity in perturbative treatments is the ultraviolet, one, where processes involve arbitrarily large energies. Surely, when the energy becomes bigger, gravity should become more and more important, and the space–time geometry, more and more nontrivial. Yet, in the perturbative treatments, one uses a fixed, continuum background space–time. Because space–time geometry is a dynamical entity in general relativity, it seems clear that in quantum gravity we cannot *presuppose* what the microstructure of geometry must be; we should let the theory itself tell us. Of course, one might have been lucky and made the right guess at the start. But the failure of perturbative methods tells us that this was not the case with the continuum hypothesis.'

Might quantum GR exist nonperturbatively, i.e. as an exact theory?

'Yes, it might. We do not have any clear evidence to the contrary. Incidentally, there do exist theories in three space–time dimensions which are nonrenormalizable but exactly soluble. Note that I am *not* saying that quantum GR must exist nonperturbatively. However, since there are qualitative reasons to expect that the nonperturbative theory will be very different from the perturbative one, the question is well worth investigating. More importantly, even if the answer turns out to be in the negative, the exercise will have been extremely worthwhile because it has already provided many new mathematical and conceptual tools to construct quantum field theories without a background space–time. Like many others, I firmly believe that, at a fundamental level, the final solution will have to be background-independent; space–time will emerge only as an approximation. And we have very little experience with quantum field theories which have an infinite number of degrees of freedom and which do not use a background space–time.'

Do you see the need for a fundamental revision of the present concepts on which the standard model is based? In other words, are we in need of a conceptual revolution to solve this problem? I once spoke to Bill Unruh, and he did not think QG could be obtained through 'tinkering with mathematics'. He said we needed to feed in new conceptual ideas.

According to Roger Penrose '...if there is to be a final theory, it could only be a scheme of a very different nature. Rather than being a physical theory in the ordinary sense, it would have to be a principle – a mathematical principle whose implementation might itself involve nonmechanical subtlety.' Is this your point of view as well?

'I believe that, at a fundamental level, the continuum picture has to go. This would be a profound change, in terms of both physics and mathematics since the picture is embedded so deeply in the conceptual fabric of physics. So, I agree with Bill that "tinkering" with mathematics alone will not suffice. However, I also feel that new mathematics *will* be needed. (I mean mathematics that was not previously used in physics.) This has happened with most big breakthroughs in physics. Newtonian physics needed calculus, general relativity needed differential geometry and quantum mechanics, Hilbert spaces and operator algebras. Indeed, without access to new mathematics, it would not have been possible to formulate new questions, let alone analyse them! Certainly, what Roger suggests is a possibility.'

Most approaches to the QG problem seem to take QM at face value, and try to modify GR in some way, or take GR as a weak-field limit. This is the case for superstring theory, where GR appears as a low-energy limit. The dimensional nature of the basic Planck units – the Planck length, time, and energy – lends credence to the idea that a QG theory could reproduce GR in regimes well away from the Planck scale. If QM is only an approximate theory itself, which fails to hold at Planck scales, then in the spirit of Roger Penrose's suggestion, QM will also have to undergo a revision. Abhay feels that this is in part why *all* attempts at quantum gravity that are being pursued are likely to be incomplete. 'However', he says, 'it is very difficult to provide concrete models of how QM should be revised. I think the best bet is to push all viable approaches to the end and if cracks develop, they will suggest how we should change QM.'

Loop variables gravity seems like a conservative approach compared to superstring theory. One major difference is that according to your programme, quantum gravity can be obtained without a unification of all forces. In the superstring theory, such a unification is vital for consistency. To be consistent, superstrings also need supersymmetry (a mathematical relationship between bosons and fermions) and higher spacetime dimensions (nine space and one time). The extra six spatial dimensions are supposed to be compactified into a very small region. Do you see these differences as complementary or conflicting issues? 'On the whole, I think the differences are complementary. String theory provides powerful constraints on allowable interactions. On the other hand, it has proved difficult to analyse string theory nonperturbatively, without assuming a background space–time. As I indicated above, our approach provides concepts and tools for a background independent approach. Over the last year or so, more concrete calculations have been proposed which may pull the two approaches closer.'

'I should also point out that we do not have a proof that quantum GR exists nonperturbatively. However, the tools required to analyse this issue finally exist. It is possible that we will find e.g. that supersymmetry or some specific couplings are necessary. This year is an exciting one for our programme because we have begun to analyse such issues.'

I spoke to Peter Bergmann (one of the founders of the geometrodynamical route to QG, and a coworker of Einstein) while I was an undergraduate and he was very skeptical of superstrings. Is it the same with you, considering most of the work in this field has been grounded in perturbation theory?

'I am perhaps more impressed than Peter by the mathematical successes of string theory. I agree that the use of a background space–time is a severe weakness. However, the very recent results due to Ashoke Sen (see note 7) and others on black holes within string theory are providing some glimpses of the possible relation between perturbative results and nontrivial geometries.'

Unlike the other forces, the gravitational force is nonlinear. In contrast, the electrical forces are linear because the total force due to a number of charges is just the sum of the forces due to each charge acting alone. This situation corresponds to the vector law of addition. Now in the case of gravity, we have a nonlinear combination of forces. This is because all forms of energy act as a source of gravity and inertia. This is true for the gravitational potential energy existing between two separated masses. Thus, the total gravitational force involved when two objects interact does not follow the usual linear vector addition law. Is this nonlinearity one of the root causes of all the problems in quantizing gravity?

'This profound nonlinearity is part of the difficulty. But this part is technical. The most important difficulty, in my view, is conceptual: it lies in the fact that gravity is encoded in the very geometry of space–time. To quantize gravity, one has to quantize geometry. One has to learn to do physics and mathematics in the absence of space–time.'

I guess one of the things the readers want to know is how everything reduces down to the picture of an apple falling from a tree. Newton's idea of a 'force' pulling the apple down is intuitive. In GR, this picture was replaced by the concept of the curvature of a four-dimensional spacetime continuum. The apple's mass curves the spacetime, and the Earth's mass curves the spacetime. This curvature tells how the masses should move. The two masses feel the combined curvature, and fall towards each other. In QFT, this 'attractive' picture is replaced by the concept of the exchange of particles called gravitons. The gravitons mediate the gravitational pull. Does the loop variables theory preserve this idea?

'Yes. Although in our approach gravitons do not exist at a fundamental level, in the low-energy approximation one can identify certain loop states with gravitons and then the picture is the one you indicate.'

'Incidentally, the loop variables also have a direct experimental significance. If you move an electron around a closed loop in a gravitational field, its spin undergoes a rotation. The basic loop variable just measures this rotation. Furthermore, if you know the rotation for all closed loops, you know the gravitational field completely.'

One of the problems with gravitons is that they seem to make sense only when the gravitational field of GR is linearized, i.e. split up into a flat space metric, and a perturbation. Gravitons are like ripples in a flat space–time background. Conventional particle theory tries to quantize these undulations, while leaving the background classical. When the background starts curving noticeably itself, what reference is there for these ripples? The problem seems to be that the arena and performers cannot be distinguished anymore.

'Gravitons are indeed ripples on a space–time background. In the perturbative approach, one does quantize these undulations, leaving the background untouched. In our approach, the situation is different. Very roughly speaking, Minkowski space by itself is represented as a quantum loop state – which we call a weave – and certain nearby states – embroidered weaves – can be thought of as gravitons propagating in Minkowski space. However, as I indicated above, the picture works only for low energy gravitons. In this regime, one can distinguish the arena from the performers.'

Geometrodynamics

Abhay's programme takes conventional GR coupled to matter as the leaping point. It is based on the 'canonical' approach to QG, whereby the full four-dimensional spacetime is split up into an observer-dependent 3+1. The first step in any canonical approach is the Hamiltonian formulation of the theory. This was achieved in the early sixties by Dirac, Bergmann, Arnowitt, Deser, Misner and others. In their formulation, the basic variable is the metric on the three-dimensional space; it captures the intrinsic geometry of the hypersurface. The Hamiltonian framework was, therefore, baptized 'geometrodynamics' by Wheeler. Unfortunately, in this framework, the equations of the theory are complicated and, therefore, as far as the full theory is concerned, the quantization programme itself did not really take off.

In geometrodynamics the canonical variables are the intrinsic geometry and the extrinsic curvature of the 3D spatial hypersurface (which is embedded in a 4D Riemannian spacetime). The subject has close links with Gauss' theorem Egregium.

Abhay explains: 'The intrinsic geometry of a three-dimensional hypersurface is the geometry of space that we can "experience directly". It tells us, for example, how to measure lengths of curves lying in the surface. The extrinsic curvature, on the other hand, tells us how the surface is embedded in the four-dimensional space–time. To see the difference, let us go one dimension down and consider a cylinder embedded in a

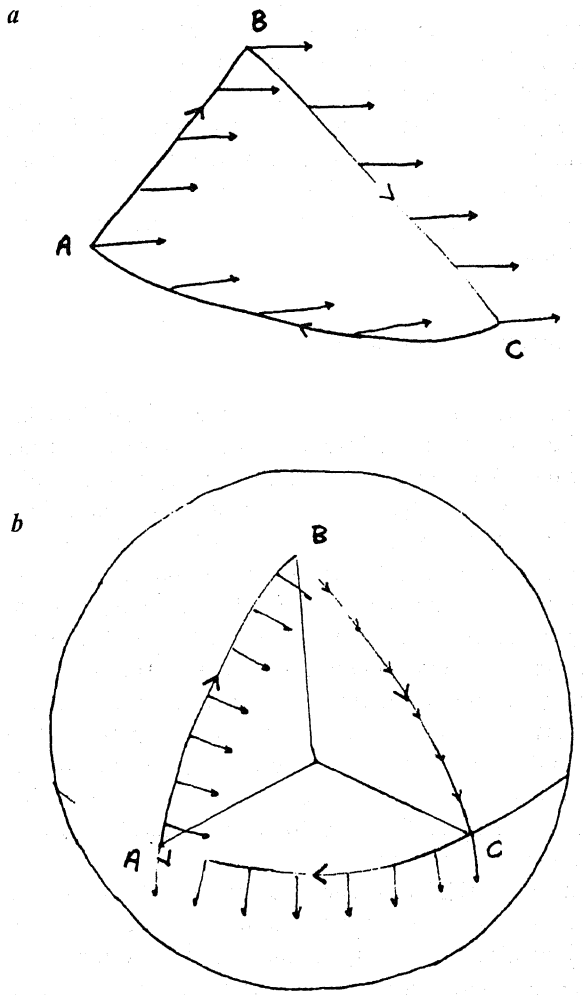


Figure 2. Extrinsic curvature: *a*, This is a parallel transport of a vector around a closed curve (ABC). The curve is drawn on a 2D sheet, embedded in 3D Euclidean space. There is no rotation of the vector, meaning there is no extrinsic curvature. *b*, Parallel transport of a vector along geodesics on the surface of a sphere, embedded in 3D Euclidean space. The vector is rotated 90°. The extrinsic curvature of a 3D spacelike hypersurface embedded in 4D spacetime is measured similarly. To obtain the curvature at a point on the surface, the closed curve (ABC) is pinched down infinitesimally.

three-dimensional Euclidean space. Since the cylinder can be obtained by rolling up a piece of paper, its intrinsic geometry is the same as that of the paper, i.e. a two-dimensional plane. The difference lies in how the paper and the cylinder sit in three-dimensional space. Technically, their extrinsic curvature is different.'

'Coming back to GR, the extrinsic curvature measures how the intrinsic geometry is changing in time. So, if we think of the intrinsic geometry as the configuration variable of general relativity, as one does in geometrodynamics, then extrinsic curvature can be thought of as the conjugate momentum. In quantum geometrodynamics, one would subject the two to the Heisenberg uncertainty relations.' (Figure 2)

By splitting spacetime into (3+1)D, are you treating the spatial and time coordinates on a different footing? Physically, this would correspond to choosing a special observer whose wristwatch keeps track of the distortions in the 3D spatial hypersurface. This method is very different to the 'covariant' schemes of quantization like the path integral approach.

'That is quite right. From aesthetic considerations, it would be nice to use, say, path integrals. However, no one has seen a way to make mathematical sense of path integrals in GR beyond certain simple minisuperspaces (which result when you freeze all but a finite number of degrees of freedom of the gravitational field and replace a quantum field theory problem by a quantum mechanics problem). The mathematical framework that my colleagues and I have developed over the last two years is, in principle, also applicable to the Euclidean path integral approach. However, there are two key difficulties. The first is conceptual. Even if one did have a complete Euclidean theory, it seems very difficult to extract physical predictions from it since, in quantum gravity, there is no analogue of the 'Wick rotation', which replaces the time coordinate t by it in Minkowskian quantum field theories, thereby enabling one to pass from the Euclidean to the Lorentzian regime (i.e. from Schwinger functions to the Wightman functions). The second difficulty is technical, associated with the specific form of Einstein's action.'

One of the main criticisms of the approach is that it breaks the general covariance of GR. Would the general covariance concept have any meaning if the continuum picture of spacetime is lost? One of the ideas brought up by your programme was the possibility of spacetime being combinatoric instead of geometric in nature, at the Planck scale.

'For technical clarity, I should first point out that, while canonical approaches do lack *manifest* covariance, they are, nonetheless covariant; for example, the full Poincaré group has a well-defined action on the phase space of electromagnetic fields in Minkowski space. With this side remark out of the way, let me answer your question. If anything resembling our approach is correct, then, in the quantum theory, there will be no such thing as a space–time geometry at a fundamental level. The picture, as you say, will be combinatorial and, therefore, the diffeomorphism group will not have a preferred role. Space–times will arise only semi-classically. In this approximation, one can ask if there is four-dimensional diffeomorphism invariance. The answer will be in the affirmative. However, it will be arrived at from the Hamiltonian picture; the four-dimensional covariance will not be manifested. This is a drawback of the approach but only from an aesthetic viewpoint.'

'Incidentally, for these reasons, I had first tried to use the covariant phase space for general relativity and

avoid the 3+1 splitting. That approach faced technical problems and I now believe that, even if the technical problems could be resolved, it would not lead to an interesting theory. I will not be surprised, however, if there is another way to ensure manifest covariance in the semiclassical regime.'

By casting GR into Hamiltonian form, it is found that the theory is a dynamically constrained system. These restrictions go by the name of the Hamiltonian and diffeomorphism constraints. What physical significance do they have?

'Constraints of this type signal the existence of a large gauge group. In electrodynamics, for example, there is an analogous constraint, the Gauss law, which says that the electric fields should be divergence-free. It ensures that the classical (and quantum) theory is gauge-invariant. Higgs pointed out quite early in the game that the diffeomorphism constraint of general relativity is rather similar. It ensures that the spatial diffeomorphisms – active coordinate transformations on the three-dimensional hypersurface – do not change physics. This constraint is universal in the sense that its form and meaning is the same for all gravity theories in which there is no background metric.'

'The Hamiltonian constraint is more tricky. It is responsible for time evolution, i.e. dynamics. If you treat it in the same fashion as the diffeomorphism constraint, one is led to what people call "the frozen (time) formalism", in which nothing evolves and physical states are represented by entire space–times. There is nothing wrong with this picture. It is like doing Hamiltonian dynamics in terms of constants of motion; it is, therefore, inconvenient from technical and interpretational perspectives.'

I have heard that the constraint equations are (high-order) polynomials in terms of the basic canonical geometrodynamical variables – the three-metrics and extrinsic curvatures. What effect does this have on trying to quantize the theory?

'It simplifies the technical problems of quantization enormously. In quantum field theories, what one might naively think of as operators are really operator valued distributions. Just as products of the Dirac delta distributions are ill-defined, products of these "operators" are also ill-defined. This is the origin of the infinities. So, if you have an expression which is non-polynomial in your basic operators, in general, there is very little chance that you would be able to regulate it and extract a meaningful operator. If the expression is a *low*-order polynomial, the chances of success are much greater. At various levels of rigour, this simplicity has been exploited by Rovelli, Smolin, Brügmann, Gambini, Pullin, Morales, Nicolai and Matschull to solve the quantum constraints. No such solutions exist in quantum geometrodynamics.'

'A simplification came in the mid-eighties when it was realized that there is another way of obtaining the Hamiltonian formulation where the basic variable is a connection which enables one to parallel transport chiral fermions. Thus, general relativity can also be regarded as connection dynamics. This formulation has two key advantages. The first is conceptual: general relativity is brought closer to gauge theories which govern all other basic forces of Nature. The second simplification is technical: equations of the theory become low order polynomials.'

The Ashtekar variables

At this stage, you came up with the idea of the Ashtekar variables. Where did the inspiration of these new variables come from? Was Amitabha Sen's work a major influence?

'For me, personally, a lot of the inspiration came from results on chiral solutions to the Einstein equations by Newman, Penrose and Plebanski in the mid-seventies. In a certain sense, this sector of Einstein's theory is completely integrable. Therefore, it seemed natural to try to base quantum theory on chiral variables. Sen's work was definitely an important influence up to a certain point. About the same time that Sen published his papers, Horowitz and I also had some results on positivity of the Hamiltonian of GR (for open universes) which used similar techniques. The two together suggested the direction that I finally took.'

What physical picture can you give us of them? You perform a canonical transformation of the old geometrodynamical variables, obtaining a connection and a triad as the new variables. A complex, group-valued, self-dual, spin connection is hard to visualize. In what way does a triad of orthonormal vectors on the three-slice take over the role of the extrinsic curvature?

'The connection enables us to parallel transport chiral fermions along closed loops and, therefore, has a direct physical meaning. Roughly speaking, the connection knows both about the (spatial derivatives) of the triad and the extrinsic curvature (the time derivative of the triad). If you think of the three-metric as the analogue of the position variable q in quantum mechanics and extrinsic curvature as the analogue of p, then the connection is analogous to the complex variable $z = q - ip$, which one often uses to construct the so-called coherent states in quantum mechanics. Clearly, if you know (q, p), you know (z, q) and vice versa. One can do quantum mechanics with (z, q) as basic variables, although it is somewhat unconventional. In quantum GR, we are led to connections and triads because these are the variables that simplify the equations.'

The actual canonical transformation is nonlinear. The result casts GR as a dynamical theory of connections. The phase space of GR is now seen to be embedded in that of Yang–Mills theory (a gauge theory). The constraints form surfaces which define restricted motions on

this phase space. This hidden relation seems remarkable. Were you expecting such a relation, or did it just drop out of the working?

'I knew that if the triads and connections can be shown to be canonically conjugate, the embedding you refer to would be a consequence. But it was far from obvious to me that the Poisson brackets between triads and connections would be so simple. Also, because of some subtle differences between the connections that Sen was using and the ones I was led to use, it was not obvious to me that all of Einstein's equations would be low order polynomials in the triads and connections.'

The next step is the transition from classical GR to quantum GR. By using these Ashtekar variables, you are trying to quantize a theory of connections, instead of a geometrodynamic theory based on spatial three-metrics. In terms of connections, the constraint equations of GR bear a great resemblance to those of *non-Abelian* Yang–Mills theory.

'Progress came about because there already existed a rich machinery to deal with quantum gauge theories. We did have to make some important changes eventually because in Yang–Mills theories, one makes a heavy use of the background Minkowski metric and our framework had to exist without reference to any background structures. But a number of key ideas came from Yang–Mills theories.'

'Incidentally, because all other basic interactions can be formulated in terms of connections, the geometrodynamic formulation did create a distance between GR and other gauge theories. For example, Weinberg, in the introduction to his book (see note 8) emphasizes this point. However, both Einstein and Schrödinger had presented a formulation of general relativity with connections, rather than metrics as the basic variables. The reason the idea did not catch on, I believe, is that their equations were even more complicated than those of geometrodynamics. They used affine connections and simplifications occur with chiral ones. I became aware of this piece of history only recently.'

Loop variables

In QM we have operators and states. Operators act on states, and take them from one allowed state to another. The simplest example of a QM system may be the simple harmonic oscillator. There the raising and lowering operators take a particle subject to a constant restoring force, to different energy eigenstates. The canonical variables, position and momentum, are raised to the status of operators, and they have to satisfy commutation relations. What are the corresponding operators and quantum states in this approach?

'This is a somewhat technical point and I hope you will bear with me. In particle mechanics, we have the notion of configuration space – the space of positions, for example – and quantum states are functions on this space. In field theories, the situation is more complicated. States are now functions on a *quantum* configuration space which is a genuine enlargement of the classical configuration space and the measures which dictate the inner product are typically concentrated on the exotic, nonclassical configurations.'

'The precise domain space of quantum states is a well-defined completion of the space of gauge equivalence classes of connections. This space can be constructed without reference to a background metric and we have also developed integral and differential calculus on this space to define Hilbert spaces and operators. There is no background metric or connection anywhere. This calculus tells us that there is a well-defined "nonlinear duality" between connections and loops and, hence, one can also represent states as suitable functions of loops. The connection and the loop representations are "dual" to one another in the same sense as the position and the momentum representations in quantum mechanics are dual. In practice, issues related to the Planck regime are often more transparent in the loop representation while semiclassical questions are generally easier to analyse in the connection representation.'

'For technical reasons connected with diffeomorphism invariance, quantum states are represented by objects which are more general than functions in the connection representation, while in the loop representation, one can regard them just as functions of loops. In either case the basic quantum operators are associated with loops and strips, i.e. ribbons. Their commutator algebra is surprisingly simple; commutators can be expressed in terms of rerouting of loops and strips, and intersections of loops with strips, and strips with strips. It is a pretty, geometrical picture.'

In the loop representation, quantum states arise as 'functionals' of Wilson loops. A deep relation exists between the equivalence classes of loops and the theory of knot classes, invariants and polynomials. There is also a relation to Chern–Simons theory.

'This comes about because there is a specific "nonlinear duality" between loops and connections: Given a closed loop and a connection, one obtains a number, the value of the trace of the holonomy of the connection around the loop. It turns out that this duality implies that there is a 1–1 correspondence between certain functions on the loop space and measures on the quantum configuration space. Therefore, we can take these loop functions as quantum states. One can then formulate the diffeomorphism constraint rigourously and seek its solutions. Not surprisingly, in the loop representation, the solutions are (certain types of) knot invariants. Thus, after you have imposed the diffeomorphism constraint, you can say that the quantum configuration space is the space of knot classes and all knot

invariants/polynomials are the potential quantum states. At a heuristic level, one expects the Chern–Simons theory to define a diffeomorphism invariant measure on the space of connections and these ideas have, in fact, been exploited by Gambini and Pullin to obtain solutions to the Hamiltonian constraint. Whether such results can be made rigorous is an open question; one would have to wait and see if the current work by mathematicians in this domain leads to useful results.'

Are you feeding in what the microstructure of space–time should look like beforehand, or does it come out of the equations? I have heard the analogy of Planck space–time being like a mesh of mail armour, made up of loops weaved together.

'A key point in our approach is that we do not start out assuming what quantum geometry should be like but let the theory lead us to it. (Of course, the framework as a whole makes certain assumptions – there should be no background structure and the Wilson loop operators should be well-defined – but they are of a general nature). We construct operators that correspond to geometry and ask for states which, when probed with these operators, would approximate a classical geometry at scales much larger than the Planck scale. We then obtain specific states which have this property but which display a discrete structure of a definite type at the Planck scale. These are the states that look like three-dimensional chain mail. The gravitational field is excited only at the loops in the chains. However, on coarse graining, the states are indistinguishable from classical geometries. More importantly, we find that spectra of basic operators such as the area of a given two-dimensional surface are quantized in the units of the Planck area.'

'In the loop representation, all operators act by breaking, rerouting and gluing of loops. These operations will code the quantum gravity interactions. So, in the Planck regime, the familiar Feynman diagrams will be replaced by "topological" diagrams representing these operations. Feynman diagrams will arise only in a low-energy regime, where, as I indicated above, the concept of gravitons is meaningful.'

What was Profs Smolin and Rovelli's inspiration to come up with the loop representation? Has there been any collaboration with the Trias and Gambini group, which is working on gauge theories?

'As I recall, they were trying to solve the diffeomorphism constraint and realized that the solution is "obvious" in the loop representation. At that time, we did not have the mathematical machinery involving measures on the quantum configuration space and it was hard to see how to construct solutions to this constraint in the connection representation. Therefore, their realization was a real breakthrough. Curiously, none of us knew about the work by Gambini and his collaborators at that time. One of the students in our group, Brügmann, came upon their papers while applying the "loopy ideas" to Yang–Mills theory and told us about them. We then contacted Gambini and Trias. Since then, Gambini, Pullin and others have made some very significant contributions. We are all extremely happy with these synergetic developments.'

You can also bring in supersymmetric matter couplings.

'Yes, supersymmetry can be brought in. There is work in this direction by Jacobson, Matschull, Nicolai and others. The work by Nicolai and his colleagues on three-dimensional supergravity has been especially illuminating; it showed that supergravity does allow an infinite number of physical states rather than just, say, a single solution analogous to the Hartle–Hawking wave function.'

Current work in the programme

Let us talk about some of the current research problems in the field. In the language of connections, you have to complexify the phase space of GR, since you have mixed (both complex and real) variables. Now you have to restrict the phase space to real portions, since the physical observables must be real quantities, not complex ones. In other words, you must implement reality conditions in the quantum theory. Have these been dealt with satisfactorily?

'Several special cases had been treated satisfactorily over the last few years. These include certain Bianchi models and midi superspaces with a single Killing field. Over the past year, we have been able to treat the *general case*. In the harmonic oscillator case, the Segal–Bargmann transform enables us to pass from the Schrödinger representation, where the wave functions $\psi(q)$ are complex valued functions of q, to the holomorphic representation, where they are *holomorphic* functions $\psi(z)$ of z. Since we know that q and p are self-adjoint in the Schrödinger representation and since the Segal–Bargmann transform is unitary, you know automatically that the reality conditions also hold in the holomorphic representation; you do not have to check it explicitly. We have constructed a rigorous analogue of this transform for quantum gravity. So, in principle, the problem has now been solved. However, we still have to develop calculational tricks to make the transform useful in practice.'

One of the main problems has been to define an inner product (vital to make sense of probabilities) in the Hilbert space. What is the status of this search?

'This problem arises at two levels: kinematical and dynamical. One generally needs an inner product on the "kinematical" states prior to imposition of constraints to make sure that the constraint operators are well-defined and that there are no anomalies in the constraint algebra. This part is taken care of by the recent mathematical developments. Furthermore, as I indicated above, the

diffeomorphism constraint has been regularized and solved. There are no anomalies. However, at the rigorous level, we still do not have a complete treatment of the Hamiltonian constraint. Very recently, the corresponding operator was constructed by Jerzy Lewandowski in Warsaw but we are yet to examine the question of anomalies. If there are none, we can construct a complete set of physical states. Fortunately, by now there are well-developed strategies to find the physically appropriate inner product and the question is if one of them will be easily implemented. However, it is quite possible that to ensure that there are no anomalies, we would have to bring in framed loops and quantum groups and/or supersymmetry. Mathematical machinery does exist to do this. And I would find it quite exciting if e.g. it is the dynamics of quantum gravity that ushers quantum groups into physics.'

'At a heuristic level, there has been a lot of progress on the issue of solutions to the Hamiltonian constraint and Rovelli and Smolin have introduced approximation techniques to find the inner product. These are useful guidelines for rigorous work. However, the problem of inner product on physical states is yet to be faced head-on.'

'Incidentally, if the programme is successful, we will have a quantum theory of gravity at a level of rigour that exceeds the current level in four-dimensional quantum field theories. This may seem like an overkill. However, since we have so little experience in nonperturbative QFTs, particularly in the absence of a background space–time, this level of care is needed both to ensure that we have not ignored some important subtleties and to convince the skeptics that a solution has really been found.'

How is the problem of time evolution handled? If there are only Hamiltonian constraints, and no Hamiltonian, how do you define a time variable, and evolve the quantum system?

'Two approaches have been followed, in both of which the notion of time is an approximate one. The first is some work I completed in 1989, where we saw that, in the connection representation, one can make a certain truncation of the theory in which the quantum Hamiltonian constraint can be written as the Schrödinger equation, where one of the connection components serves as time. This shows how the familiar evolution of QFT will arise in the low-energy regime. The second and more recent approach is due to Rovelli and Smolin. They couple gravity to a scalar field and use the scalar field as time. So, while we still do not know how to extract time and evolution in the Planck regime – and, like many of my colleagues, I feel this is not necessarily a meaningful thing to ask – in suitable approximations, time evolution has been recovered.'

For posterity, can I have your feelings as to where loop variables are heading?

'There are three parts to the answer. The first refers to quantum gravity, the second to other physical theories of connection, especially QCD, and the third to certain branches of mathematics.'

'Within gravity, as I indicated above, for the first time, we have a candidate for the quantum configuration space and the diffeomorphism constraint has been formulated without anomalies, and we know its general solution. If we can do the same for the Hamiltonian constraint – possibly by bringing in framed loops and quantum groups – one could say that quantum GR exists nonperturbatively. It is like saying, in QCD, that we have a representation in which the Hamiltonian is rigourously self-adjoint. This would be striking but not immediately solve problems of physical interest. The situation would be the same in QGR. However, that the theory exists, one could then look for reliable approximation methods and know that this is a meaningful programme. Many such methods are already being developed. I believe that it is crucial to continue to look for such methods.'

'Since the mathematical machinery that has been developed works for any theory of connections, it is tempting to apply it to QCD. We have already done so in two space–time dimensions and obtained several new results. The most notable among these are closed expressions for the Wilson loop Schwinger functions and a proof of equivalence of the Hamiltonian and Euclidean path integral methods. One might venture further and try to extend these methods to three and four space–time dimensions. That they will lead to mathematically interesting quantum field theories is clear. Whether these theories will be as useful in physics is an open issue. In any case, it is exciting that one and the same methods are being applied to theories of all basic forces of Nature.'

'On the mathematical side, there have also been some interesting new results. A few years ago, it was widely believed that spaces of gauge equivalent connections would not admit *any* nontrivial diffeomorphism-invariant measures. Several of us have found infinite families of such measures by now. The relation between knots and these diffeomorphism-invariant measures is equally exciting. Our methods also enable one to extend (sufficiently nice) invariants of ordinary knots to those of generalized knots, where loops are allowed to intersect and can have kinks and overlaps. This is of interest to knot and graph theorists. Such results arise because we are looking at the familiar structure from a new angle, with a new perspective. Such contributions, I believe, will continue.'

Superstrings[22–25]

Perhaps the most popularized of all the recent approaches to QG is superstrings.

Superstring theory proposes that the elementary constituents of matter are one-dimensional curves, rather

than point particles. According to the theory, the quarks, leptons and gauge bosons of the standard model (SM) arise as excitation states of a truly fundamental entity – the superstring. These excitations come from rotational or vibrational degrees of freedom (rather like the harmonic modes in a violin string), or from internal degrees of freedom like supersymmetry (SUSY) and Lie group symmetries. If they exist, superstrings would be the smallest things in nature. They would be about 10^{-33} cm long, and reside in the weird world of Planck scale physics. Superstring excitations energies are about 10^{18} GeV, or 10^{-5} g. These particle masses are way too big to be detected by current accelerators, including the large hadron collider (LHC) being built in Europe. We are looking at detecting particles as massive as bacteria!

Superstrings can come in two varieties. One resembles a line segment with free ends. This type is called the open superstring. The other type is a loop with the topology of a circle – the closed superstring. Both versions reside in a ten-dimensional (9+1) spacetime.

Since we only see four (3+1) dimensions in real life, it is assumed that the six extra spatial dimensions are curled up, in a region as small as the Planck scale. The process of curling up is called compactification. There is no mechanism in the theory to tell how you curl the extra dimensions up, and this arbitrariness is a cause for concern. Theorists have explored Calabi–Yau spaces, group manifolds, and other spaces as candidates. The idea of compactification is reminiscent of Kaluza–Klein theory, which attempts to unify gravity with electromagnetism using an extended spacetime of 5 or (4+1) dimensions. This theory was extensively expanded in the 1970s to include the Yang–Mills theory, which gives for example, the type of non-Abelian gauge theory used in weak interactions (this involves a spacetime of dimension greater than 5; e.g. 12 for SU(3) internal symmetry). The mathematical techniques of these larger-dimensional spacetimes (including what is known as 'dimensional reduction' – the means whereby one gets back to the physical dimension 4) have been much used in discussions of supergravity and superstring theory. However, it is important to emphasize that these developments all work at the level of the *classical* field equations: the quantum theory used in quantising them is essentially standard.

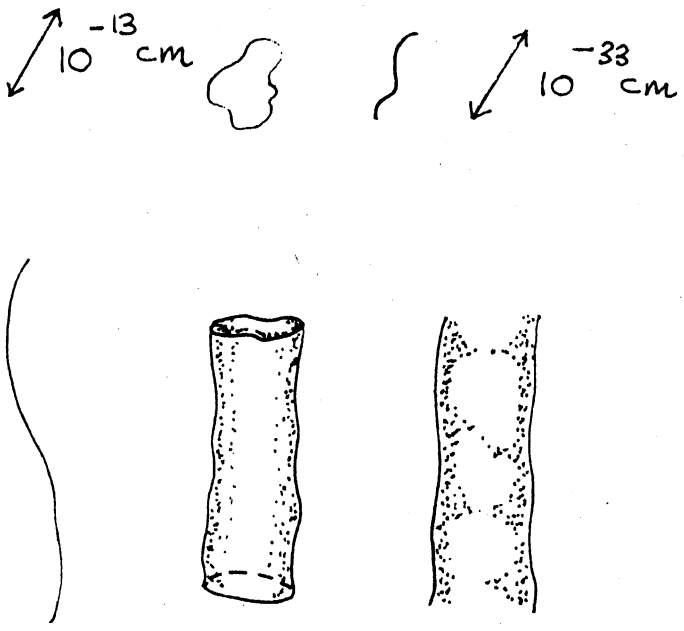
String theories have an extraordinarily rich mathematical structure. Exploring their symmetries, described by various algebras, has been a major focus of work in the field. It has emerged that the same mathematical structures appear in many different fields. For example, as it moves through spacetime, the string traces out a world sheet or cylinder. Like the world lines (geodesics) of point particles, this world surface is constrained to be of extremal area. The symmetry properties of these surfaces are similar to those encountered in two-dimensional condensed-matter systems. There has been valuable cross-fertilization between these fields.

Superstring theory is also related to subjects like 2D conformal field theories, nonlinear sigma models, WZW models and other integrable models. It has associations with 2D supergravity, Lie superalgebras, and W-algebras, the latter being world-sheet symmetry algebras of bosonic string theories. Quantization leads to problems with 'anomalies' in these algebras, whereby classical symmetries are violated at the quantum level. Work is still being done on anomalies in W-algebras and also more generally in Lie algebras.

The vibrational spectrum of open superstrings includes a massless spin-1 gauge boson associated with a Yang–Mills group – SO(32) or $E_8 \times E_8$. These groups are needed for anomaly cancellations. For the closed superstring, a massless spin-2 particle arises. It has been identified as the graviton, the conjectured carrier of the quantum gravitational force.

GR is taken to be the large-distance or low-energy limit to the superstring. Strings seem like point particles at weak energy scales (10^{-16} cm) since it is many orders of magnitude less than the superstring scale (10^{-33} cm). A small extended object looks like a point from the perspective of lower energies. (Figure 3)

By examining string interactions, it is found that the existence of open strings implies closed strings. Closed strings alone can form a consistent system. It follows that every consistent string theory necessarily includes gravity, since closed strings have gravitons in their excitation spectrum.



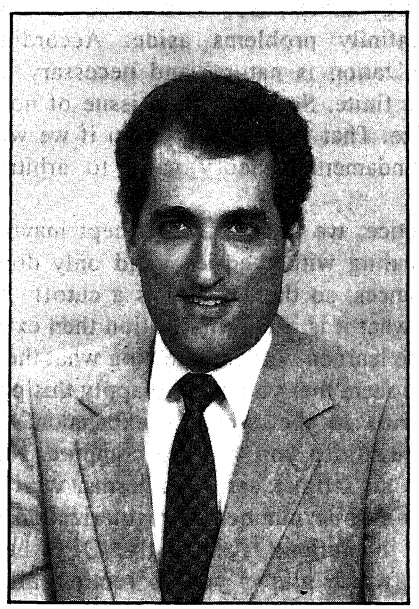


Figure 3. From particles to strings. Point particle theories describe physics well at weak scale energies, but it is possible that at Planck scales, particles are actually tiny strings. World lines would then be replaced by world cylinders and sheets. See *Superstrings*, Vol. 1, M. Green, J. Schwarz and E. Witten, Cambridge University Press, 1987.

People have tried to generalize strings to higher-dimensional objects, like P-branes. However, it is very hard to make quantum theories of extended objects and get them to satisfy physical consistency constraints like causality and unitarity. In fact, the more extended you go, the harder it is. The success of string theory relies on conformal symmetry, which is a property solely of 2D world sheets.

The self-consistency of superstrings is heavily dependent on two experimentally undetected phenomena: supersymmetry and higher spacetime dimensions.

Ed Witten is at the Princeton Institute of Advanced Studies, New Jersey. He is a major contributor to superstring theory. He was once a history major at Brandeis, but had some science background. His interest in superstrings was sparked by a review article by John Schwarz. He says: 'Schwarz's review article made it easier to start learning about developments in superstring theory than it had been before – but my concentrating on reading it was, of course, a result of the fact that I was already very curious about superstrings.'

Edward Witten

Quantum field theory began when Planck tried to explain the emission spectrum of black body radiation. He postulated that energy was emitted discontinuously in discrete units, or quanta. Later, from a statistical analysis of the radiation field, Einstein suggested it was not just the emission and absorption of radiation which was quantized, but also the actual electromagnetic field itself – in the form of photons. This idea was confirmed experimentally by the Compton effect. Naturally, there were attempts to extend the quantum field idea to the classical gravity field, described by a metric tensor in Einstein's GR. The basic excitation of the quantum gravity field would be spin-2 radiation, which results from the symmetric nature of the metric tensor. How hard would it be to detect the gravitational analogue of the photon – the graviton – given the weakness of the gravitational interaction? Ed replies: 'Classical gravitational waves (for which there is indirect evidence from timing measurements of the binary pulsar) could be directly detected by laser interferometers – perhaps eventually giving also an important new window into some exotic phenomena in astrophysics. It is also possible that a very long wavelength cosmic background of gravitational waves could be detected by timing measurements involving space ships and pulsars. These experiments could indeed possibly verify directly the spin-2 nature of gravitational waves.'

'Unfortunately, there is no experiment in sight that could directly verify the quantized nature of the gravitational field.'

The gravity field is different from the other force fields since it plays a dual role. On the one hand, it defines the arena in which other fields interact. Yet, gravity itself is a participant in the interaction. Does QFT assume that spacetime is flat to all energy scales, i.e. has a Minkowskian spacetime signature even at Planck scales? 'QFT as we know it, without quantizing gravity, works on a fixed space–time manifold, which for most obvious purposes we can take to be Minkowski space. There is then a continuum space–time down to arbitrarily small distances.'

Gravity is highly nonlinear since the gravity field couples to mass–energy. The gravitational field gravitates. Is this a major conceptual subtlety when we try to quantize gravity? 'There are some conceptual issues in quantizing gravity, but it is not at all clear that they are decisive. What to me is the decisive difficulty is the problem of the infinities that arise when one tries to quantize the usual theory.' (It is instructive to contrast this point of view with Abhay's, stated earlier on.)

Renormalization, infinities and anomalies

QFT works with perturbation expansions around a Minkowskian background. Terms in these expansions are represented diagrammatically by Feynman diagrams. The Feynman diagram has an attractive interpretation as a representation of an actual physical process, and (though limited to perturbation theory) this picture has some validity.

In QED interactions between photons and electrically charged particles are linear. However, the situation is different with gravitons. Since energy gravitates, two gravitons can bend each others path. Gravitons can also emit and absorb other gravitons and couple to the other gauge bosons.

QFT introduces the concept of a particle's self-energy. Let us take the electron self-energy as an example. According to QFT, there is a difference between a

bare electron and a physical electron. A bare electron is an unphysical entity because it has no radiation field around it. Such a radiation field is known to exist because of Heisenberg's uncertainty principle, which allows for the presence of a blanket of virtual photons. When a bare electron interacts with this virtual field, the bare electron is converted to a physical electron. This self-interaction affects the energy of the bare electron, and hence its mass. Quantities like charge are affected as well. In fact, all physical quantities are affected by the self-interaction.

When the Feynman integrals are evaluated for these self-energy terms, the integrals diverge to infinity. A similar phenomenon occurs when we calculate the photon self-energy in the form of vacuum polarization diagrams.

The first order terms (tree level) are finite, but the higher-order terms (the radiative corrections) involving closed loops diverge. Physically, the difficulties arise as a result of the point particle concept. Heisenberg's principle says that energy conservation can be violated locally such that the relation $\Delta E \cdot \Delta t > \hbar$ is obeyed. Since an electron is taken to be a point, emission and reabsorption of a virtual photon need take no time at all. So the virtual photon can have an infinite amount of energy. This contributes an infinite mass to the physical electron, since it must haul around the virtual photon blanket. Other properties of the electron get affected similarly.

Despite these shortcomings, QFT is one of the most successful theories we have. On this Ed says: 'Just because we write down a quantum field theory Lagrangian containing some fields does not mean that we know what the particles are going to be. QCD is an example where the particles (mesons and baryons) do not even appear in the Lagrangian (which contains quarks and gluons). Even if the particles are in natural one-to-one correspondence with the fields, as in QED, the masses of particles cannot be just read off from the constants in the Lagrangian. It is necessary to compute all kinds of quantum corrections. The fact that the nature and masses of the particles are, in large part, computed and not postulated, is a manifestation of the fact that the QFT description of nature is more thorough than its predecessors.'

To handle these divergences, QFT invokes the principle that energy cannot be measured, only differences in energy can be. A scheme called renormalization was developed by Feynman, Tomonaga and Schwinger back in 1947 to take care of this, for QED.

To handle divergent graphs, we firstly impose cut-offs on the integrals. This modifies the theory into another one. The cut-offs set some energy scale limit to the theory's predictions. Ed comments: 'The cutoff theory has physically unacceptable properties, so it is necessary to remove the cut-off and "renormalize". This is just as well, since the cut-off is arbitrary and if one did not have to remove it one would lose most of the predictive power. In good cases, like QED, after renormalization the parameters in the quantum theory are in one-to-one correspondence with the classical parameters; thus, in QED the only parameters are the charge and mass of the electron (the mass can be scaled to one by a convenient choice of units).'

The second step is to renormalize the theory by incorporating the blanket of virtual particles around the bare particle. This converts the bare particle into a physical one. In the process, relations between bare and physical quantities are introduced. These relations contain renormalization constants. Thirdly, we revert from the renormalized theory to the original QFT by taking the limit when the cut-offs go to infinity. This restores the original theory. The divergences reappear, but only in the renormalization constants relating physical and bare quantities. Like the bare quantities, the constants are not observable. The original integrals, written in terms of physical quantities, become well-defined and finite to all energy scales! So, in a sense we have shifted all the infinity problems aside. According to Ed: 'Renormalization is natural and necessary even if the effects are finite. So there is no issue of not having to renormalize. That would be so even if we were dealing with a fundamental theory valid to arbitrarily short distances.'

'In practice, we are always (except maybe in string theory) dealing with theories valid only down to very short distances, so there really is a cutoff – we just do not know what it is. Renormalization then extracts whatever can be learned without knowing what the cutoff is.'

It would seem that you have to apply this procedure to all the terms in the S-matrix expansion, for all the physical quantities you want to compute. Now the expansion is an infinite series of terms, which seems to require an infinite number of regularization and renormalization operations. Amazingly, QED has a gauge invariance which allows you to remove all the divergences from the measurable quantities to all orders of perturbation expansion, via just one type of renormalization.

Why cannot we compute physical quantities directly, instead of going via this roundabout? Feynman himself thought that renormalization was 'sweeping the problem under the carpet'. He thought that we should be able to formulate a theory such that we get zero ground state energy from the very start. What physics could we be missing here? One possibility, already mentioned by Abhay, is that the infinities ultimately arise from neglecting effects in Planck scale physics which would have a subtle effect on low energy physics.

When we try to fit gravity into QFT, the algorithm is to linearize the GR field by choosing a coordinate system in which the metric tensor can be expressed as

$g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}$, where $\eta_{\mu\nu}$ is the Minkowski metric and $h_{\mu\nu}$ is a small perturbation such that $|h_{\mu\nu}| << 1$. This small perturbation, a tensor field, is subject to quantization on a Minkowski background which provides the causal structure. It is treated as the 'graviton' particle.

'Formally, there is no problem in constructing the perturbation expansion of the S = matrix along the above lines. The only real difficulty is that one meets ultraviolet divergences that cannot be renormalized away (without introducing new parameters absent in the classical theory).'

At the one-loop level pure QG's divergences can be renormalized away. However, the divergences arising at the two-loop level cannot be removed without robbing the theory of predictive yield.

On the associated problems of anomalies in QG he comments: 'The existence of a quantum theory is always delicate. Once one writes down a classical Lagrangian, one does not automatically get a quantum theory. Infinities and anomalies are two of the main ways to fail. Anomalies that affect gauge invariance are even worse than lack of renormalizability; they mean that the perturbation expansion of the quantum theory just does not make sense.' Essentially, the time rate of change of some quantity is zero in the classical theory and upon quantization this rate becomes nonzero, breaking some symmetry and, hence a conservation law.

Recent work in superstrings

How does extending the idea of particles to superstrings change things? An analogy would be helpful here. Let us take the decay of the free neutron, which is mediated by the weak force. We know that the old Fermi theory of weak decay is not renormalizable. However, the electroweak theory is. The electroweak theory replaces the point interaction of the old Fermi theory by inserting a massive W boson propagator, which mediates the decay. The theory is now renormalizable. Virtual supermassive superstring excitation states affect the renormalizability of superstring interactions by 'softening' or spreading out the interactions.

Ed says: 'Certainly, in going to string theory, everything becomes softened, and eventually finite. How best to understand it is not yet clear, but somehow the ultraviolet region is missing in string theory.'

Although the superstrings are extended objects, their interactions still take place at single spacetime points. However, this point depends on the Lorentz frame of the observer (the pants diagram phenomena) unlike the point particle case. There the spacetime interaction point is identical in all Lorentz observer frames. Thus there is less freedom in constructing string theories compared to the point particle case. This is why we have only a finite number of superstring theories instead of the infinite number of point field theories. (We have to choose the correct point particle QFT via phenomenology.) (Figure 4)

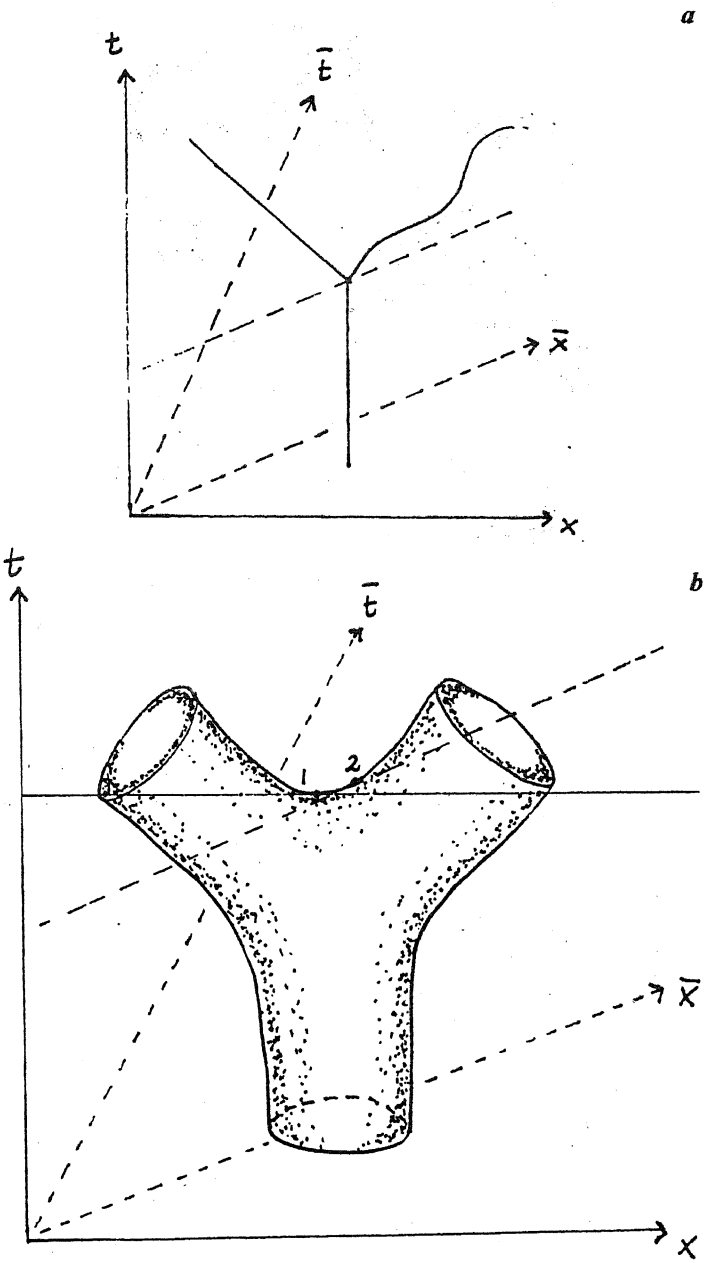

Figure 4. Contact interactions for particles and strings. *a*, Interactions between particles occur at a single spacetime point, called the vertex in the Feyman diagram approach. This point is Lorentz-invariant since it is the same in all reference frames. *b*,. The splitting of a closed string into two closed strings, otherwise known as the pants diagram. The world surface is a cylinder, so the interaction region is no longer a point. One observer will see the interaction occur at point (1), and another will see it occur at (2). The contact point is no longer Lorentz-invariant. Divergences in QFTs of point particles can arise when two sharp vertices get arbitrarily close to one another. Renormalization is needed to remove the ultraviolet divergences by introducing ultraviolet momentum cutoffs, thereby 'fuzzying' out the vertices. Since string diagrams are surfaces, they tend to accomplish this process automatically. See *Quantum Field Theory of Point Particles and Strings*, B. Hatfield, Addison-Wesley, 1992.

According to one counting scheme, there are currently three d=10 superstring theories (type I, type II, heterotic) and although they have no adjustable dimensionless parameters, there are many mathematically consistent solutions which seem to satisfy the superstring equations of motion. Choosing physically representative solutions phenomenologically seems no different to inserting SM parameters by hand. The problem of finding physical solutions can only be solved if we know how compactification works. Doing this we can find the ground (vacuum) state of the theory. From there, we can work out the low-energy excitation spectrum, find the ratios of the excitation masses, and determine couplings constants from the topology of the compactified space.

Ed is optimistic about this arbitrariness: 'The attractive near-uniqueness that string theory appears to possess in principle is largely lost in practice because one finds a plethora of possible classical solutions. Hopefully, in time we will learn something new – perhaps connected with the question of why the cosmological constant vanishes – and the nature of the issue will change.'

On the problem of formulating a nonperturbative theory of superstrings, Ed says: 'My work with Nathan Seiberg (and related work he did by himself) led to some new results about nonperturbative behaviour of some quantum field theories, but not yet to new results on nonperturbative behaviour of string theory.'

String theory appears to admit a group of discrete field transformations, called S-dualities, as exact nonperturbative quantum symmetries. How could these symmetries help in formulating a nonperturbative QG theory of strings?

'I don't know yet, but I think it is a very exciting clue. S-dualities are symmetries that have no real analogue in our previous experience in physics (they do persist in some field theories – including some of those I studied with Seiberg – which are related to low energy limits of string theories).'

Particles trace out world lines, but strings trace out world sheets or cylinders, which can be treated as Riemann surfaces. When the Feynman diagrams are worked out for the closed string, it is found that they become finite order by order in the genus expansion.

Ed says: 'In string theory everything is finite – there is no need for renormalization.'

'Feynman diagrams are replaced by Riemann surfaces; these have much additional symmetry and structure, and this is related to some of the known wonders of the subject – there are surely also unknown wonders (S-duality is a hint of them), but since they are unknown I cannot tell you about them.'

On the matter of progress on the physical principles behind superstrings which should generalize Einstein's equivalence principle, he replies: 'The new physical principles haven't yet been found. It is hard to say how much progress there has been, since some of the things that have been learned may well turn out to be important clues.'

Superstrings are supposed to reside in ten spacetime dimensions, but we are really only speaking approximately. The phase space of the superstring consists of all the possible orientations and states the string can be in. What are the problems of formulating superstrings directly in four spacetime dimensions from the start? Are not superstrings supposed to generate spacetime, instead of just residing in it, since superstrings have gravitons in their excitation spectrum?

'It is true that in our present understanding ten spacetime dimensions is the classical solution of string theory with the maximum symmetry. Exactly how strings can be so smart as to generate space–time is still a mystery, but they do.'

'You can formulate strings "directly in four dimensions from the start" but then you do not have the degree of uniqueness that one has in ten dimensions. That is why the theory is often said to be ten-dimensional.'

There is no mechanism in superstring theory which tells us how the extra dimensions should compactify. Feynman said about superstrings: 'I don't like it that they're not calculating anything. I don't like it that they don't check their ideas. I don't like it that for anything that disagrees with experiment, they cook up an explanation – a fix-up to say "Well, it still might be true". For example, the [superstring] theory requires ten dimensions. Well, may be there's a way of wrapping up six of the dimensions. Yes, that's possible mathematically but why not seven? When they write their equation, the *equation* should decide how many of these things get wrapped up, *not* the desire to agree with experiment ....' What is your response to this remark?

'Some of the predictions are indeed checked. For instance, strings predict gravity while prestring physics makes quantum gravity impossible. This prediction has been tested – and the result is one of the main reasons for the interest in string theory.'

Are you familiar with the Ashtekar canonical gravity programme? If you are, do you think that the programme is founded on valid physical assumptions?

'Some of the work in that programme is interesting to me. I'd personally be surprised, however, if it turns out that conventional general relativity exists as a nonperturbative quantum field theory.'

Do you think the LHC will shed any light on low-energy superstring phenomenology? The detection of supersymmetry partners could be crucial. To explain the absence of SUSY partners at low energies we have introduced the idea of the spontaneous breaking of supersymmetry, analogous to the Higgs mechanism for electroweak symmetry breaking: one facet of the SM which is unconfirmed is this mysterious Higgs field which pervades all spacetime, which makes the electroweak

theory work by giving masses to particles, and which we have no shred of evidence for.

'Apart from gravity, supersymmetry is one of the general predictions of string theory. Therefore, confirming it at the LHC would give a big boost to the whole effort. Moreover, if supersymmetry is observed, it won't be just that experimentalists will say "Yes, there is supersymmetry". They will observe a plethora of superpartner masses and couplings. There is a reasonable hope that in all that data there will be clues to how string theory should be done – or tests of theoretical ideas that may have emerged in the meantime.'

I asked Ed what the inspiration for his ideas was. Did he manipulate page-long equations in his head? Did he deal with concepts, and then phrase everything in maths later on? Where Einstein, Galileo and Newton were different from everyone else was they could ask really simple questions which had shattering consequences for existing physical theories. Was this Ed's modus operandi too?

To this he replied: 'I am afraid I don't work on the cosmic scale you are suggesting. Most of the time I am bogged down doing nothing, and whatever success I have has come by focusing on a very little bit of the total picture.'

Outlook

It is clear from the discussion that we are a long way off from even the foundations of a full theory of QG. Despite some famous claims, the end of theoretical physics is still not in sight. I asked Chris about possible lines of future investigation.

'I think that the superstring programme and the Ashtekar programme are currently the only two really viable approaches to trying to construct a full quantum theory of gravity, and I, therefore, support strongly work on both fronts!'

'Myself, I have long been bothered by the use of continuum ideas in both quantum theory and classical general relativity, whereas both programmes do take this for granted. So I would like to be able to get away from this, but the problem is to find a theoretical framework that does not seem to be contrived and artificial. One of the many reasons why the superstring and Ashtekar programmes *are* so important is that they do not have this contrived nature: within their own terms, each has quite compelling reasons for taking it seriously.'

'Similarly, I (like Roger Penrose) believe in my heart that quantum theory itself needs to be changed radically to reflect our changing conception of space and time. But, again, it is difficult to do this in a way that is believable to one other person than the author of the paper (Salam's definition of what it means to say that a theory is worth taking seriously!).'

Ed Witten gives this advice to those who want a try at superstrings: 'It is hard to give general advice to young researchers. But people who want to learn strings should definitely make sure that along the way they get a thorough knowledge of what is known in particle physics and how it can be (more or less) derived from strings.'

As to where superstrings are heading he has this to say: 'Lots of really nice things have been discovered, and that will continue. Sooner or later, probably far in the next century, the underlying unifying ideas will be discovered and then the physical landscape will be very different from what we can imagine today. If we are lucky and work hard, maybe we will live to see the day!'

Faint star counts and the Milky Way structure

Devendra Ojha

The Milky Way Galaxy offers a unique opportunity for testing theories of Galaxy formation and evolution. Here we discuss how large surveys, both photometric and astrometric, of galactic stars are the keystones in investigations into such fundamental problems as the merging history and future of the Galaxy. This work features a sample survey plan to produce probes of stellar populations in the Milky Way. Objectives of this work are to trace the fine structure of our Galaxy through the statistical study of the stellar distributions according to their luminosity, colours and proper motions. This involves two steps: first, acquiring a new photometric and astrometric sample survey in various galactic directions; and second analysing the data using a model of population synthesis and determining the properties of populations in the Galaxy and constraints on the scenario of formation and evolution.

THE field of galactic structure is currently extremely active, due mostly to improvements in observational capabilities and the realization that our Galaxy is perhaps the one best-suited to test theories of Galaxy formation. The concept of stellar populations has proved to be one of the most useful ideas of modern astronomy. Most simply, it is the idea that we can define a population as a set of stars that possess shared characteristics such as composition, age or kinematics, and that we can use the properties of various stellar populations to de-

termine the structure and evolutionary history of the Galaxy. The first modern definition of stellar populations was given by Baade[1] who defined two stellar populations – the now famous populations I and II – based on colour-magnitude diagrams and on the brightness of resolved stars in M31 and M32. Population I is composed of stars found in the disk of our Galaxy and in the Magellanic Clouds; a signature of this population is the presence of highly luminous O- and B-type stars and open clusters. Population II is made up of stars with colour–magnitude diagrams like galactic globular clusters, which lack luminous blue stars; another signature of population II is the presence of short-period Cepheid variables. Now it became clear that population II was old and poor in metals, while population I was metal-rich and contains both young and old stars. The various doubts and worries about the population I/II scheme came to a head in the famous Vatican Conference[2] of 1957, during which Baade's original two populations were replaced with five: extreme population I, older population I, disk population, intermediate population II, and halo population II. Since the Vatican Conference, the field of stellar populations has been advanced significantly, and we now have a wealth of detailed information on populations throughout the Galaxy. One of the main developments is that we now have a good picture of the intermediate population (thick disk) in our Galaxy, i.e. a component with characteristics intermediate to those of the thin disk and halo populations[3].

Studies of stellar populations often take as their starting point large-scale surveys, with selection criteria involving one or more observable variables. The physical location of the stars is arguably the most important constraint. With these points in mind, we have carried out a sample survey in UBV photometry and proper motions in various directions in the Galaxy. Large Schmidt telescope plates are well suited for measuring photometric magnitudes and positions for a large number of stars, because they have a large field ($5° \times 5°$) and go sufficiently faint. By choosing a reasonable number of fields in various galactic directions, we expected to get a representative sample of the spatial distribution of the different stellar populations, which have led to an understanding of the history of formation and evolution of the whole Galaxy. The kinematical studies of stellar populations are very important because they follow the galactic dynamics and retain the memory of the evolution of the whole potential. The results discussed here concern the kinematics of thin disk and thick disk populations of our Galaxy and the scenario of formation for the thick disk population.

Observations and data reduction

The chosen directions constitute a complete set of fields at high and intermediate latitudes:

- Direction towards the galactic anticentre[4] ($l = 167°$, $b = 47°$).
- Direction towards galactic centre[5] ($l = 3°$, $b=47°$) near the globular cluster M5.
- Direction towards the galactic antirotation[6] ($l = 278°$, $b = 47°$).
- Direction towards the North Galactic Pole[7] ($l = 58°$, $b=80°$)

The basic observational material for the survey is Schmidt plates. The plates used in our programme have been taken from Palomar, Tautenburg, European Southern Observatory and Observatoire de la Côted'Azur (France) Schmidt telescopes. For each field the plates have been taken in UBV filters. In all we have a total of 58 plates for the various fields. Each plate has been scanned with the MAMA (Machine Automatique à Mesurer pour l'Astronomie) machine at Paris Observatory. A sampling step and pixel size of 10 μm has been used to scan the plates. The output of the MAMA machine is a catalogue of objects giving the positions X and Y, integrated density and the area of each object. The integrated densities are used to calibrate the plates photometrically, while a combination of various Schmidt plates of a given field is used for proper motion determination involving a time base of ~34 years. To calibrate the plates photometrically a number of photometric standards are required. The standards should cover the entire range of magnitudes and colours to be studied. To obtain photometric standards we have observed a number of subfields in each field using the CCD system attached to the 1-m Sampuranand telescope of the UP State Observatory at Nainital, India. A few standards have also been observed using the 1.2-m telescope of Observatoire de Haute-Provence in France. Our final photometric and astrometric survey contains 55,000 stars covering a 50 square degree field.

Kinematical analysis

The distance of each star in the catalogue was determined by estimating the absolute magnitude, which was obtained from a M_v vs $B–V$ relation of main-sequence stars of solar metallicity, taking into account the metallicity change as a function of the distance from the galactic plane. The cardinal components of the stellar space velocity (in km/s), U, V and W (where U is defined as positive in the direction of the galactic anticentre, V is positive in the direction of galactic rotation, and W is positive in the direction of NGP), were derived from proper motions, μ_l and μ_b (in arcsec per year) and line of sight distance d (in pc)[8].

The major factors contributing to distance errors are the photometric errors in the colour of σ_{B-V} and magnitude σ_V. From our surveys, we expect the mean errors in

$\sigma_{B-V} = 0.1$ and $\sigma_V = 0.07$ for $V = 11$–18. From these values, our estimate of error of about 20% in distance seems to be realistic up to $z = 3$ kpc, where z is the distance above the galactic plane.

Kinematics of stellar populations

The kinematical properties of each stellar population are related to their spatial distributions. Scale height, velocity dispersions and asymmetric drift are linked by the Boltzmann equation. The proportion of each stellar population varies with the distance above the galactic plane and the selection of a stellar sample at a given distance allows one to optimize the proportion of one population. Since kinematical data allow one to improve this identification of populations, we have minimized bias from mutual contamination of each population at a given height by performing a kinematical separation of populations. To perform the kinematical separation, we have used a maximum-likelihood method (Stochastic Estimation Maximization (SEM) algorithm)[9] in order to deconvolve the multivariate Gaussian distributions and estimate the corresponding parameters. The aim of the SEM algorithm is to resolve the finite mixture density estimation problem under the maximum-likelihood approach using a probabilistic teacher step. Through SEM one can obtain the number of components of the Gaussian mixture (without any assumption on this number), its mean values, dispersions and the percentage of each component with respect to the whole sample. We have used this method to separate the 2-D Gaussian velocity distributions (U, V) to identify the two components (thin disk and thick disk) of the Galaxy[10]. A multivariate discriminant analysis[11] is also used to distinguish the thick disk from other populations with the help of the model of population synthesis[12–14].

Thin disk population

For the thin disk population, we observe a continuous increase of velocity dispersion with height[4,5]. It can be explained by the fact that the thin disk is a mixture of disks with various scale heights and velocity dispersions, since the disk is not formed in isothermal components. This results in a vertical gradient of velocity dispersions, since the disk is not resolved in isothermal components. For the thin disk population, we obtain a measure of the kinematic gradients, which appear to be

$$\frac{\partial \ln \sigma^2_{U+W}}{\partial R} = -0.18 \pm 0.03 \text{ kpc}^{-1}$$

and

$$\frac{\partial \ln \sigma^2_{V}}{\partial R} = -0.05 \pm 0.02 \text{ kpc}^{-1}.$$

R is the galactocentric distance projected upon the galactic plane. Our results[10,11] confirm that the thin disk has a relatively short scale length of ~2.3 ± 0.5 kpc and scale height of ~258 ± 50 pc.

Thick disk population and the merging history of the Milky Way

The thick disk population has been revisited under the light of these new data. We used also other photometric and astrometric sample survey in complementing direction, like the pole[7].

The sample of stars in two fields (galactic centre and anticentre) have been divided into 6 or 7 bins of distance, and in each bin of distance a fit has been performed with a SEM algorithm to identify the Gaussian (U, V) components corresponding to the different populations[4,5]. The thick disk population has been identified as a discrete and distinct component. In our present study[11], the thick disk population appears to be isothermal, since the kinematical characteristics are nearly constant along the line of sight and so that there is no vertical gradient. For this reason, the velocity characteristics for this population are much better defined. For the thick disk population, the kinematic radial gradients appear to be almost zero:

$$\frac{\partial \ln \sigma^2_{U+W}}{\partial R} = -0.008 \pm 0.01 \text{ kpc}^{-1}$$

and

$$\frac{\partial \ln \sigma^2_{V}}{\partial R} = +0.02 \pm 0.02 \text{ kpc}^{-1}.$$

By combining the kinematical results deduced from our four surveys (galactic centre, anticentre, antirotation, and NGP), we have derived the velocity ellipsoid of the thick disk population[11]. The mean kinematic parameters are: (σ_U, σ_V, σ_W, V_{lag}) = (72±4, 54±3, 40±3, 40±10) km/s. The most probable values of scale height and local normalization for the thick disk component are determined to be h_Z ~759±50 pc and $A_{\text{thick}} = 7.4^{+2.5}_{-1.5}$% of the disk. The ratio of the number of thick disk stars in the galactic centre region to that in the centre region yields h_R ~ 2.8–3.7 kpc for the scale length of thick disk[11].

These properties have been compared with several scenarios of formation. 'Top-down' models, where the thick disk forms through a dissipational collapse, after the halo formation and before the thin disk has completely settled down, are in contradiction with the data, since they infer a continuity in the characteristics of the thick disk and thin disk and large kinematical vertical gradients. Alternatively, 'bottom-up' models suppose a formation of a thick disk after the complete collapse of the thin disk. We can eliminate those where the thick

disk formed from a secular kinematic diffusion of thin disk stars (which would produce a continuity between thin and thick disks). It remains a scenario well in agreement with the present data: the thick disk could have been formed from the dynamical heating of the thin disk during the sink of a small galaxy into the Milky Way. This merging event has to happen at the beginning of the thin disk life time so that the gas can cool again and form stars in the long-lasting thin galactic disk that we see now. This violent bottom-up scenario leaves two important observational signatures. First the thick disk is a separate population distinct from the thin disk and the halo. Second, no gradient can be generated in the thick disk by the event, although a preexisting gradient may survive the merger.

Conclusions

The thick disk population is found from all points of view (density laws, kinematics and metallicities) as a population well separated from the thin disk. It shows no gradient either on abundance[3] or on kinematics. The results emerging from the present study of the correlations between photometry and kinematics give a mounting evidence that the thick disk of the Galaxy is most likely a sequel of a dwarf satellite galaxy merging in the Milky Way disk during the early epoch of this disk. This interpretation emerged from an accurate characterization of the thick disk properties: the scale height and the scale length of this component have been established; its rotation and velocity dispersion turned out to be quite distinct from both the disk itself and the halo. The local density of the thick disk component is twice what was previously assumed and the stellar colours do not reflect any significant chemical gradient.

REVIEW ARTICLE

A unique and remarkable binary pulsar

Simon Johnston

Research Centre for Theoretical Astrophysics, University of Sydney, NSW 2006, Australia

PSR B1259–63 is one of the most remarkable pulsars ever discovered. It is the only pulsar known to be orbiting a main-sequence Be star and forms the 'missing link' in the evolutionary scenario of binary stars. Its orbit is highly elliptical and every 3.5 yr it approaches to within 0.5 AU of its companion star. Its pulse profile is unique among pulsars and shows that the opening angle of its emission cone exceeds 180°. Observations made around the time of closest approach of the two stars show changes in the pulsar's dispersion measure, rotation measure and fractional linear polarization on very short timescales. The pulsar is observed to spin down during the periastron passage. The companion star to the pulsar has been monitored at optical and UV wavelengths. The system is a radio and X-ray transient and has been detected at γ-ray energies, with the high-energy emission probably occurring in a shock front formed by the collision of the two stellar winds.

IN this review paper, I will discuss the remarkable binary pulsar PSR B1259–63. I will start with a general introduction into pulsars and binary systems before moving on to the specifics of the system containing PSR B1259–63. There are an increasing number of excellent conference proceedings and review articles on pulsars in general with varying degrees of complexity. Interested readers should consult refs. 1–11 and the references therein.

Almost 30 years after the discovery of the first pulsar by Hewish *et al.*[12], radio pulsars remain one of the astronomy's most exciting fields. The existence of neutron stars was predicted as early as the 1930s by Baade and Zwicky[13], who speculated that when a high-mass star (typically 5 or more solar masses, $M_\odot$) ends its life in the spectacular event known as a supernova explosion, it should leave behind a dense stellar core. Although a blue star at the centre of the Crab Nebula was postulated to be such a neutron star[14], it was little thought that they would be detectable. In 1967, however, these neutron stars were serendipitously discovered by a group of radioastronomers working at Cambridge University in the UK. The name pulsars (a contraction of the two words *pulsating stars*) is a misnomer; the stars rotate rather than pulse and the principal characteristic of a pulsar is its incredibly stable rotation rate. The radioemission originates from near the magnetic pole and the misalignment between the rotation and magnetic axes produces a regular pulse of radiation for an observer on Earth (like the oft-quoted analogy with a lighthouse).

Pulsars are now known to be highly magnetized, rapidly rotating neutron stars which originate from the supernova explosions of high-mass stars. Pulsars have masses in a tight range around 1.4 $M_\odot$ and have diameters of only ~20 km; this implies a stellar density in the region of 10^{17} kg m^{-3}. Almost 600 have now been discovered and catalogued[15]; all bar a few are located within our own Galaxy. Their spin periods range between 0.00155 and 5.4 s and their inferred magnetic fields lie between 10^4 and 10^9 T. The youngest known pulsar is 900 years old in the Crab Nebula. The oldest pulsars have ages in excess of 10^9 years, comparable to the age of the Galaxy. All pulsars are observed to spin down with time due to rotational energy losses from relativistic particles streaming from the high magnetic field.

Only ~2% of pulsars are part of a binary system. However, their importance is not proportional to their number and they provide many valuable insights into the physics and the formation and evolution of neutron star systems and their progenitors. Before the discovery of PSR B1259–63, all the companions to known binary pulsars were degenerate stars, either white dwarfs or other neutron stars. The evolutionary route of double neutron star systems is thought to occur as follows[7]: Two high-mass stars are in a mutual orbit; the more massive of the two stars evolves first and then explodes in a supernova explosion. In rare cases, the system remains bound and consists of a high-mass star and a young neutron star[16]. The high-mass stars eventually evolve, and the system goes through a high-mass X-ray binary phase (HMXB) when material from the evolved star accretes onto the neutron star surface. Eventually, the high-mass star explodes in its turn and, if the system remains bound, a double neutron star system remains. All the steps of this evolutionary chain had been observed (most famously perhaps for the double neutron star system PSR B1933+16, for which the discoverers[17] won the 1993 Nobel Prize for Physics) except the second step – the neutron star, high-mass star pair before it evolves into an HMXB. This 'missing link' was found with the discovery of PSR B1259–63 (ref. 18) and an important piece in the evolutionary jigsaw fell into place. A further example of such a system has subsequently been discovered[19,20].

It turned out that PSR B1259–63 was orbiting a $10M_\odot$ star known as a Be star (described in more detail below). Be stars[21] themselves are rather strange objects. Most stars show spectral lines only in absorption; however, the Be stars are characterized by having the Balmer series of hydrogen in emission. In the early 1930s, this was interpreted to mean that the star had a disk of material surrounding its equator which had been thrown off due to centrifugal forces from the rapidly rotating underlying star[22]. This simple model is still prevalent today, although observations, particularly at UV wavelengths, have found that this cannot be the whole story. There remains no convincing theoretical model of Be stars. The general picture, however, is that Be stars have a hot, tenuous, fast-moving wind which is thought to originate from the stellar poles. They also have a disk of material which is cool, dense and slow-moving and which follows Keplerian orbits at least for a few tens of stellar radii. In the simplest model the disk can be characterized by two parameters: an opening angle and a radial power law distribution of electron densities within this envelope[23].

Discovery

PSR B1259–63 was discovered during a search for young, distant pulsars in the galactic plane using the Parkes 64 m telescope located in NSW, Australia[24]. For a variety of reasons, the search was conducted using an observing frequency centred at 1520 MHz rather than the 400 MHz commonly employed in pulsar searches. This high-frequency turned out to be rather valuable as, most unusually for pulsars, PSR B1259–63 cannot be detected at low frequencies in short integration times.

The pulsar was interesting to us right from the moment of discovery. It had the shortest spin period (47 ms) of any of the pulsars discovered in the survey and had a rather curious double-pulse profile reminiscent of the archetypal young pulsar in the Crab Nebula (PSR B0531+21). After a successful attempt to measure the period change over a few days, we concluded that the pulsar was probably young. This encouraged us to look for a supernova remnant around the pulsar, but to our disappointment an image of the region with the Molonglo Synthesis Telescope (MOST) revealed

nothing of interest in the pulsar's vicinity.

By the middle of 1990 we realized that the pulsar was not behaving exactly as it should. In two consecutive timing observations the pulsar was extremely weak before reappearing about a month later at its usual strength. As the timing programme continued and more data points were obtained, it was evident that the pulsar's behaviour could not be explained with a simple period and period-derivative, and in early 1991 we came to the conclusion that the pulsar was a member of a long-period binary system. The most remarkable thing about the binary companion is that it had to have a mass greater than 2 $M_\odot$ and this implied that the companion was either a black hole or a high-mass star. Both possibilities were extremely interesting – all other binary pulsars to that date, of which there are anyway very few, had either white dwarf companions (with mass less than 1 $M_\odot$) or neutron star companions (with masses between 1.2 and 1.6 $M_\odot$).

A sub-arcsecond position using the Australia Telescope Compact Array (ATCA) was obtained and it turned out that a well-known 10th magnitude Be star, SS 2883, was located within the ATCA error box. Thus, the companion was a main-sequence star with a mass of ~10 $M_\odot$, the first such system discovered and an important system for our understanding of the evolutionary sequence of the millisecond pulsars. When the paper announcing the discovery of the system was published[18], not enough data had been obtained to allow an accurate determination of the orbital parameters; indeed, it turned out that the errors quoted in the parameters were much too optimistic. However, the general shape of the orbit was correct; it was highly eccentric ($e \sim 0.9$) and the binary period was in excess of a few years. This remains the orbit with the highest eccentricity out of all the known neutron star binary systems. This high eccentricity implies that the pulsar comes very close to its companion star at closest approach ('periastron').

Waiting for periastron

Although by 1992 it was apparent that periastron was still a year or more away, there were plenty of experiments needing to be done. The programme to monitor the pulsar in the radio was continuing, with data being obtained roughly every two weeks. As the time baseline increased, the binary parameters became better determined, and by early 1993 we were confident of the numbers and published them in an IAU telegram[25] with the prediction that the next periastron would occur on 9 January 1994.

At optical wavelengths, a crude spectrum of the star had been obtained[18], but in April 1993 we used the 3.8 m optical Anglo-Australia Telescope (AAT) to obtain high-resolution spectrum of the prominent hydrogen Balmer lines typical of Be stars as a class. The spectrum showed the higher-order Balmer lines and the He I line

Table 1. Observed and derived parameters for PSR B1259–63 (from ref. 27)

Right ascension, α (J2000)	$13^h\ 02^m\ 47^s.68(2)$
Declination, δ (J2000)	−63° 50′ 08″.6(1)
Period, P	47.762053919(4) ms
Period derivative, $\dot{P}$	$2.2793(4) \times 10^{-15}$
Epoch of period	MJD 48053.44
Dispersion measure, DM	146.75(8) cm^{-3} pc
Orbital period, P_b	1236.79(1) days
Projected semimajor axis, $a \sin i$	1295.98(1) light s
Longitude of periastron, w	138.6548(2)°
Eccentricity, e	0.869836(2)
Epoch of periastron	MJD 48124.3581(2)
Magnetic field, B	3.3×10^{11} G
Characteristc age, τ_c	0.33 Myr
Mass function, $f(M_p)$	1.53 $M_\odot$
Predicted periastron passage	MJD 49361.2 ≡ 1994 Jan 9.2.

in emission and thus confirmed that the star was around spectral type B1 and had a mass of ~10 $M_\odot$ and a radius of ~6 $R_\odot$. This, in turn, implies that the inclination angle of the binary orbit in the plane of the sky is roughly 35°. The optically derived distance of only 1.5 kpc is in contrast to the distance derived from the dispersion measure of 4.5 kpc (ref. 26); it is likely that the optical value is closer to the truth. The equatorial stellar rotation velocity is ~180 km s^{-1}; given the star's spectral type, the velocity is expected to be somewhat higher than this. If we ascribe the velocity difference to an inclination angle effect then the equator of the star is also inclined at 35° to the line of sight, similar to the binary orbit. Although

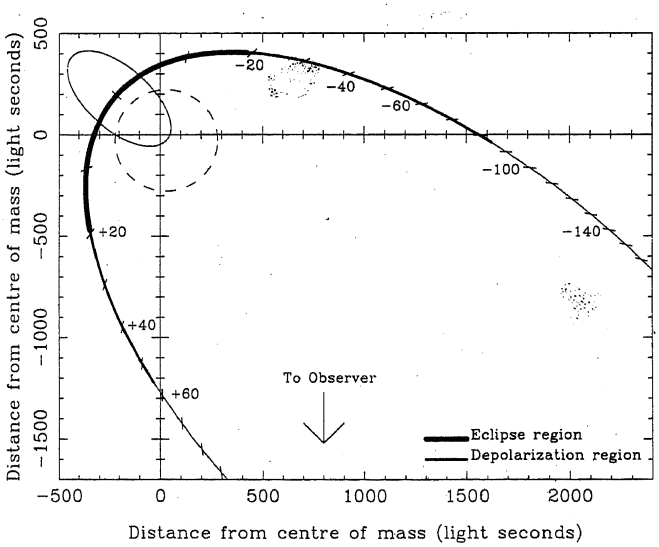

Figure 1. Schematic diagram showing the orbital path of the pulsar and its Be star companion around the time of periastron. Tick marks on the pulsar orbit are at 10-day intervals. The orbit of the Be star, assuming a mass of 10 $M_\odot$ for this star, is shown in the top-left corner, and the likely size and position of the optical circumstellar disc at periastron is shown by the dashed circle. The medium-thicknes line indicates the portion of the orbit over which the pulsed emission was depolarized, and the full-thickness line indicates the interval over which the pulsar was eclipsed. (After ref. 40)

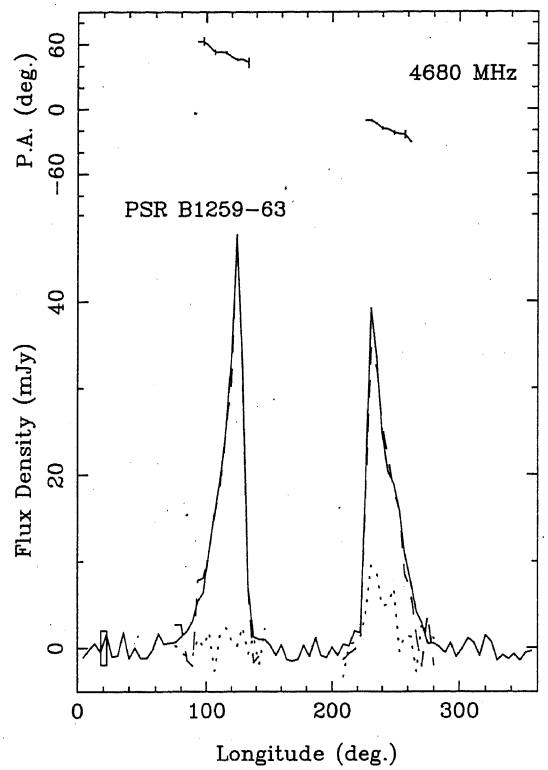

Figure 2. Mean pulse profiles and polarization parameters for PSR B1259–63 at 4.7 GHz. In the lower part, the solid line is the total intensity (Stokes parameter I) profile, the dashed line is the linearly polarized intensity (L), and the dotted line is the circularly polarized intensity (V). In the upper part, the position angle of the linearly polarized part (ψ) is plotted where L is significantly above noise, with $\pm 2\sigma$ error bars on every second point. An error box of amplitude 2σ and width equal to the effective profile resolution (including dispersion smearing across frequency channels) is visible at the left-hand end of the profile baseline. (After ref. 28)

this result is highly model-dependent it does give some indication that the stellar disk and the binary orbit are close to aligned. A combination of the optical results and the improved timing parameters for the pulsar using all the data available up to mid-1993 was published by Johnston *et al.*[27]. The observed spin and Keplerian parameters and a few of the derived parameters of the system are shown in Table 1. A schematic of the pulsar's orbit near the time of periastron is shown in Figure 1.

Radio polarization data for the pulsar were obtained at frequencies ranging between 1500 and 8400 MHz. The data show that both pulses are strongly (80%) linearly polarized at all frequencies[28]. The polarization properties of the pulsar at 4700 MHz are shown in Figure 2, which shows the pulsar in its 'conventional' profile, and this leads one to believe that the pulse shown on the left arrives at the observer before the pulse shown on the right. Remarkably, the polarization data show that convention in this case is flaunted. The data show that the pulsar emission cone must have a very large opening angle (greater than 180°) and that the pulse shown on the right actually arrives first[28]. The data also confirm that the binary inclination angle must lie close to 35°.

Observations had also begun at higher energies. Following an apparent nondetection of the pulsar just prior to apastron at X-ray wavelengths[29], the ROSAT telescope was used to observe the pulsar at two epochs just after apastron[30]. The pulsar was detected on both occasions, the second detection being roughly double the flux of the first. There was no evidence for any pulsed flux at either epoch. Cominsky *et al.*[30] considered various origins of the X-rays and ruled out that they originated from the Be star's hot coronal wind or from Roche-lobe overflow accretion. They concluded that some accretion from the Be star wind must be occurring even at such a large distance from the star. Later, the apparent nondetection was reanalysed[31] and it was found that the pulsar was, in fact, detected at a low flux level; however, this did not alter the basic conclusions in ref. 30.

Meanwhile, the theorists had not been idle. Kochanek[32] was the first out of the starting blocks and he modelled the impact of the pulsar on the equatorial disk of the Be star and the observational consequences for the optical emission lines. King and Cominsky[33] had taken the X-ray observations and proposed that the X-rays originated from low-level accretion from the tenuous (at apastron) Be star wind spherically onto the neutron star. In the model, the equatorial wind speed had to be low, only ~10 km s^{-1} and relatively cool. Later X-ray observations (see below) probably rule out this explanation. Lipunov *et al.*[34] proposed an evolutionary scenario for the pulsar and also predicted that changes in the pulsar's dispersion and rotation measures would be observed at periastron. Finally, shock theory was used [35] to model the interaction between the pulsar wind and the Be star wind and implications of the theory for high-energy observations near periastron were discussed. The conclusions were that the observations should yield a determination of the physical characteristics of both winds.

Periastron

Observations at the time of periastron were carried out from the radio through to γ-ray energies, encompassing UV, optical and X-ray energies.

Careful timing analysis of the pulsar for over 1500 days and two periastron passages came to fruition with the discovery that the pulsar had spun down slightly as a result of its periastron passage[36]. The magnitude of the spin-down is rather small, with a $\Delta P/P$ of $\sim 2 \times 10^{-9}$ and it is argued that this is a result of the so-called 'propeller

effect'[37,38]. The slowdown occurs because although the strong magnetic field of the pulsar prevents accretion onto its surface, the incoming material still interacts with the strong magnetic field at the Alfvén radius. The magnetic field 'propels' the material away from the star but at the same time the material imposes a braking torque on the pulsar. Detailed modelling of the effect in this system has been considered by Ghosh[39].

Observations of the pulsar using the Parkes radiotelescope over a few months around periastron have been discussed by Johnston *et al.*[40]. The observations showed changes in the pulsar's dispersion measure, rotation measure, flux density and percentage polarization on short timescales. This is the first time such changes have been observed in any pulsar. Essentially, the pulsar acts as an excellent probe of the wind surrounding the Be star. As the pulsar approaches its companion, it enters denser regions of the Be star's wind and the pulsar's dispersion measure starts to increase. Eventually, due to the clumpy nature of the wind, the pulses themselves become scatter-broadened and this renders the pulsar undetectable at low frequencies. Finally, a combination of pulse scattering and free–free absorption renders the pulsar undetectable for a period of 6 weeks around periastron itself[40]. On egress from the eclipse, the rotation measure and percentage polarization of the pulses varied rapidly over a period as short as a few hours. Melatos *et al.*[41]. looked at detailed modelling of the stellar environment based on the radio observations of the pulsar. They concluded that the pulsar wind cannot dominate the Be star's wind contrary to popular belief and that the best fit to the observed radio data comes from assuming that the Be star has a thick equatorial disk with a exponential density profile. The value of the stellar magnetic field and surface density are consistent with other values found in the literature[42].

Observations of the binary system were made with the ASCA X-ray satellite on three epochs around periastron[43]. The system was detected on all three occasions with an X-ray luminosity of $\sim 10^{34}$ erg s^{-1} just before and just after periastron and about a factor of 2 lower at periastron itself. As with the earlier ROSAT data, no pulsations were detected and accretion onto the neutron star surface as a cause of the X-rays can also be ruled out[43]. The most likely explanation is that magnetohydrodynamic shock acceleration processes between the pulsar and the Be star's wind are the most likely explanation for the X-ray emission. Details of this mechanism will appear in a later publication[44].

Finally, observations at γ-ray wavelengths with GRO[45], in the UV[46], optical[47] and the radio continuum[48] are all still being analysed and the results should appear in the press within this year.

Summary

I have given a brief overview of the discovery of the peculiar binary pulsar PSR B1259–63. It remains one of only two pulsars known to be in orbit around a high-mass main-sequence star. It is the only pulsar to show dynamical changes in its measured parameters and the only radio pulsar to show X-ray and γ-ray transient phenomena.

Most of the observational data are currently in press or in preparation (as of July 1995) and the publication of this material will undoubtedly stimulate further research into this system. The next periastron will occur in mid-1997 and once again both observers and theoreticians will be watching with interest.

A high-precision technique using X-ray reflectivity for the measurement of surface and interface roughness

P. V. Satyam, D. Bahr*, S. K. Ghose, G. Kuri, B. Sundaravel, B. Rout and B. N. Dev

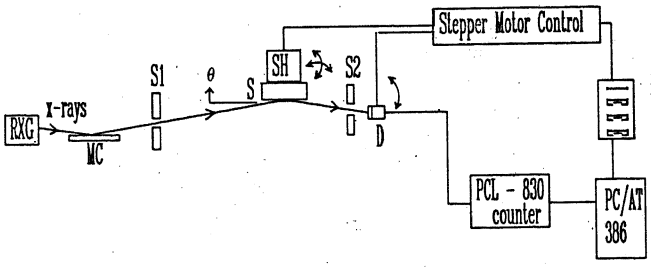
Institute of Physics, Sachivalaya Marg, Bhubaneswar 751 005, India
*Hamburg Synchrotron Radiation Laboratory, HASYLAB at DESY, Notkestr. 85, D-22603 Hamburg, Germany

Surface and interface roughness plays a crucial role in ultrathin two-dimensional layers. We have set up an X-ray reflectometry facility for the measurement of surface and interface roughness with a precision better than 1 Å. As ion implantation is one of the techniques to fabricate ultrathin buried epitaxial layers, we have explored the effect of MeV ion implantation on surface roughness in two cases: Au-implanted $LiNbO_3$(001) and Co-implanted Si(111) samples. In both cases we have observed an implantation-induced enhancement of surface roughness. In addition, for the Co-implanted samples, we found unexpected interference fringes with dose-dependent periodicity.

HIGH-quality thin films are necessary for the fabrication of lower-dimensional structures for fundamental studies and for device fabrication in microelectronics. For the growth of high-quality films the role of solid–vacuum and solid–solid interfaces is very crucial. The quality of the thin film and the interfaces should be as good as possible. Therefore, one needs experimental probes to determine this quality. Among the relevant questions to be answered are the following: (i) What is the structure of the ultrathin grown layer, or what is the initial stage of growth? (ii) For a multielemental film, which type of atoms lie in the first atomic layer at the interface? (iii) What is the coordination number of the interface atoms? (iv) What is the distance between adjacent atomic layers across the interface? These questions are answered by using a very powerful technique involving generation of standing waves of X-rays[1–4]. One would also like to know the amount of statistical disorder, or roughness, on the film surface and on the buried film–substrate interface. This information along with the film thickness can be obtained from X-ray specular reflectivity measurements. Both the X-ray standing wave and the X-ray reflectivity measurement techniques are nondestructive and the high penetration power of X-rays enables the probing of buried layers and interfaces.

For the determination of interface roughness, the problem is to determine the correct probability density function for the interface position in the direction of the surface normal. This is mostly a Gaussian distribution. Then the spread in the interface position can be evaluated. X-ray reflectivity under the grazing incidence condition is a well-established technique to investigate this spread in the position of exposed (outer) and buried (inner) interfaces[5].

We have recently set up the grazing incidence X-ray reflectivity experiment for the measurement of surface and interface roughness in the Institute of Physics, Bhubaneswar. To our knowledge, this is the first high-precision grazing incidence X-ray reflectometry facility in India. Here we present a brief description of the set-up and some preliminary results.



The experimental set-up uses an 18 kW rotating-anode X-ray source (RIGAKU 300VE) with a Mo anode. A line beam of Mo-$K_{\alpha 1}$ (17.479 keV) X-rays is selected with a symmetrically cut dislocation-free Si(111) monochromator crystal. The θ–2θ scan is performed using a HUBER four-circle diffractometer. The reflected X-rays are detected with a BaF_2 scintillation detector. The programs for the angular scans and data collection have been written in GWBASIC. A schematic diagram of the experimental set-up is shown in Figure 1. We also measure inelastic spectra, e.g. fluorescence, from the sample with a Si(Li) detector simultaneously with the reflectivity as a function of θ. The signal from the Si(Li), which first goes to a multichannel analyser, is automatically transferred to the computer (PC-386) memory along with the reflectivity data. The whole process is automated and controlled through the PC. This completes the set-up for X-ray standing wave experiment under grazing incidence specular reflection. This additional feature with the Si(Li) detector has not been shown in Figure 1. The details of the instrumentation aspect will be published elsewhere. A part of the instrumentation has already been published[6].

For X-rays the (real part of) index of refraction of any solid or liquid medium is less than unity. Thus, it is possible to obtain total external reflection from matter. For the two-media system the reflectivity is obtained from the Fresnel coefficient of reflection[5]:

$$r_{1,2} = \frac{k_{z,1} - k_{z,2}}{k_{z,1} + k_{z,2}}, \tag{1}$$

where

$$k_{z,l} \equiv k_1(\theta_1^2 - 2\delta_l - 2i\beta_l)^{1/2}, \quad l = 1, 2, \tag{2}$$

Figure 1. The schematic experimental set-up for X-ray reflectivity measurements.

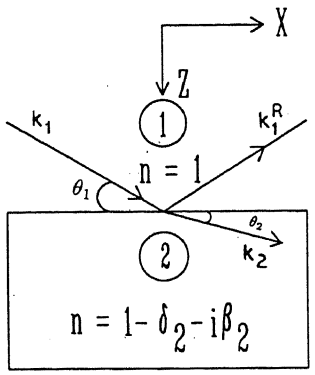

Figure 2. Sketch of X-ray reflection and refraction for a two-medium system.

θ_1 and k_1 being the glancing angle and the wave vector in medium 1, respectively (Figure 2);

$$n_l = 1 - \delta_l - i\beta_l \tag{3}$$

is the complex refractive index of the material of the lth layer. δ and β values are very small, each of the order of 10^{-5} or less. δ and β values are given by $\delta = r_e \lambda^2 N/2\pi$ and $\beta = \lambda\mu/4\pi$, where r_e is the classical electron radius, λ is the wavelength of the incident radiation, N is the total number of electrons per unit volume and μ is the linear absorption coefficient[7]. Equation (1) is valid for the s-polarized radiation. For the p-polarized radiation

$$r_{1,2}^{p} = \frac{k_{z,1}/n_1^2 - k_{z,2}/n_2^2}{k_{z,1}/n_1^2 + k_{z,2}/n_2^2}. \tag{4}$$

However, for X-rays ($n_l \approx 1$) eq. (4) reduces to eq. (1).

If the first medium is air ($\delta = \beta = 0$) and the second a solid substrate, the reflectivity is

$$R_{1,2} = |r_{1,2}|^2 = \left| \frac{\theta - (\theta^2 - 2\delta_2 - 2i\beta_2)^{1/2}}{\theta + (\theta^2 - 2\delta_2 - 2i\beta_2)^{1/2}} \right|^2. \tag{5}$$

(We have dropped the subscript of θ_1.) This is applicable for a smooth surface. (A surface is also called an air–solid or vacuum–solid interface.)

For a rough surface, the surface position can be described by a Gaussian probability distribution as introduced by Nevot and Croce[8]:

$$P(z) = \frac{1}{\sqrt{2\pi}\sigma_2} e^{-z^2/2\sigma_2^2}. \tag{6}$$

With this modification the Fresnel coefficient of reflection for a rough surface becomes

$$r_{1,2}^{\text{rough}} = r_{1,2} \exp^{-2\sigma_2^2 k_{z,1} k_{z,2}} \tag{7}$$

in the limit $\sigma_2 k_{z,2} < 1$; σ_2 is the root mean square roughness of the surface of medium 2, and $r_{1,2}$ is given by eq. (1). This result was also obtained by Sinha *et al.*[9] in a different approach within the distorted-wave Born approximation (DWBA). Thus, the reflectivity (eq.(5)) gets modified for a rough surface:

$$R_{1,2}^{\text{rough}} = \left| r_{1,2}^{\text{rough}} \right|^2. \tag{8}$$

Here we present some results of reflectivity measurements on Au-implanted $LiNbO_3$(0 0 1) and Co-implanted Si(1 1 1) single-crystal substrates. $LiNbO_3$ is a widely used dielectric material for optical waveguides. The waveguiding properties are controlled by incorporating impurities, e.g., Ti, in the $LiNbO_3$ lattice. It is important to determine the impurity site in the lattice[10]. For the lattice location of Au in $LiNbO_3$ we performed X-ray standing wave and ion-channeling experiments. These results will be published elsewhere. Here we present the results of measurements of surface roughness of an implanted sample.

Interest in Co implantation in Si arises from the fact that it is possible to fabricate a buried epitaxial $CoSi_2$ layer in Si by ion implantation of Co followed by annealing. This process is known as ion beam synthesis (IBS). The IBS-prepared silicides have received much attention as their electrical transport properties are better than those prepared by the conventional ultrahigh vacuum procedure. A possible application of an IBS-fabricated Si/$CoSi_2$/Si heterostructure is as a metal base transistor[11]. Measurement and control of interface roughness in these structures are important. The results of surface roughness measurements on Co-implanted Si(1 1 1) samples are presented here and compared with those on the virgin Si(1 1 1) sample.

Figure 3 shows the X-ray specular reflectivity from a virgin (0 0 1)-oriented $LiNbO_3$ sample as a function of the grazing incidence angle. The curve fitted to the data corresponds to a surface roughness of 9.6 Å. In order to elucidate the precision of the roughness measurement, the theoretical curves for two values of roughness of 8.6 and 10.6 Å are also shown. These curves are clearly different from the best fit to the data, implying that the precision is better than 1 Å. The theoretical curves obtained from eq. (8) have been convoluted with the beam divergence (0.05°) for fitting to the experimental data. Results from the measurement on Au-implanted sample are shown in Figure 4, which also shows the virgin $LiNbO_3$ result for comparison. The measured roughness on the implanted sample is 14.5 Å, i.e. the surface roughness has been enhanced due to implantation. (It may be noted that high-energy ion implantation can produce interesting viscoelastic effect, leading to surface smoothing or roughening[12].) We have not made measurements on the implanted sample before annealing.

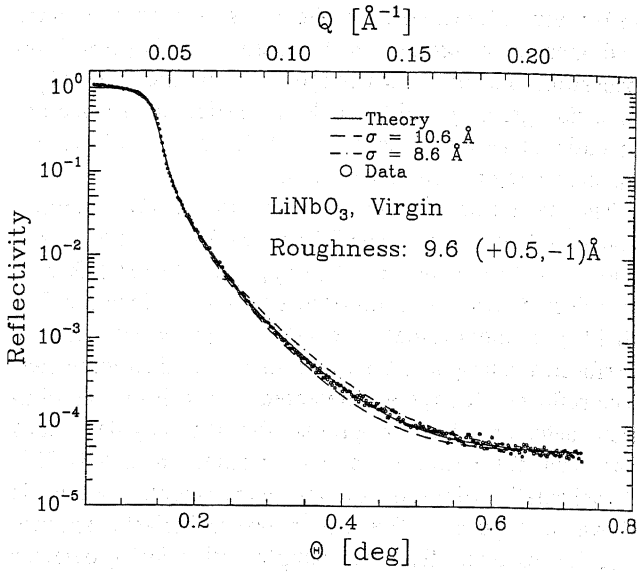

Figure 3. Reflectivity as a function of the grazing angle of incidence θ for a virgin $LiNbO_3$(0 0 1) sample. The value of the momentum transfer $Q = 4\pi \sin\theta/\lambda$ is shown on the top abscissa.

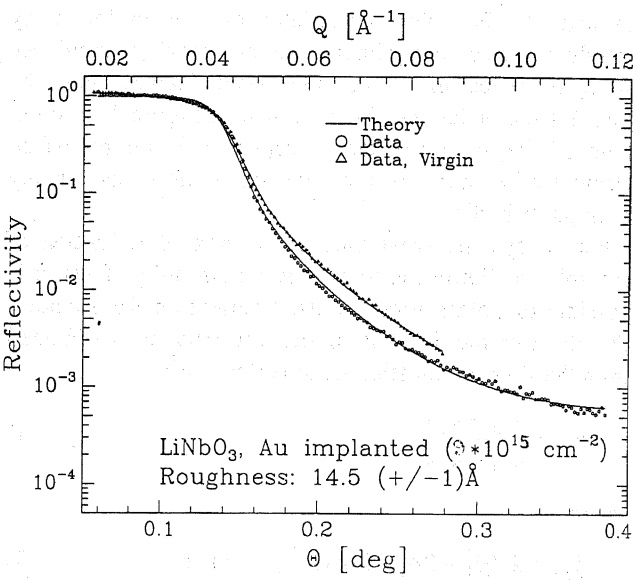

Figure 4. Reflectivity from an Au-implanted $LiNbO_3$(0 0 1) sample (O). For comparison the reflectivity from a virgin sample is also shown.

Surface roughness might have been even higher on the as-implanted sample. Au implantation was done using the 3 MV Pelletron accelerator in our Institute. 1.38 MeV Au^{2+} ions were implanted into the $LiNbO_3$ sample at a tilt angle (the angle between the surface normal and the ion beam direction) of 65°. The sample was annealed at 450°C for 40 min under flowing oxygen to remove implantation-induced lattice damage. The ion-channelling measurement showed that the bulk lattice damage was almost fully removed.

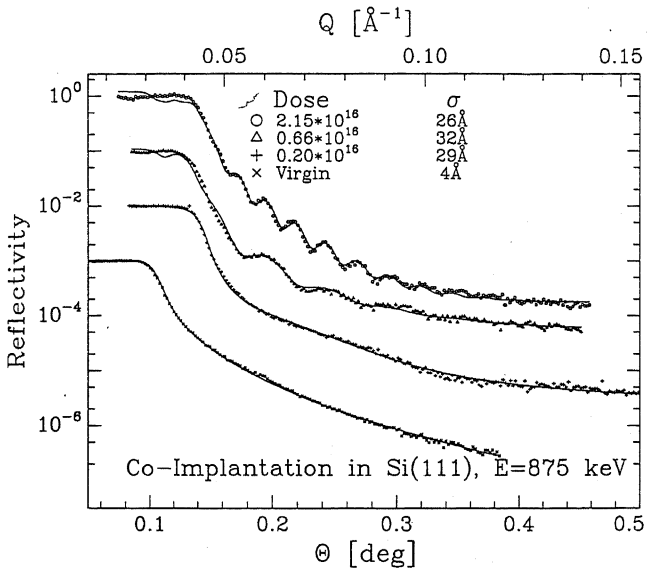

Figure 5. Reflectivity from Co-implanted Si(1 1 1) samples with various Co doses (ions/cm^2) and from a virgin Si(1 1 1) sample is shown. The surface roughness values (σ) are listed. The ordinates of the successive curves have been shifted by a decade for clarity.

Co^+ implantation was done at a tilt angle of 70°. The samples were not annealed. The reflectivity results are shown in Figure 5. A comparison with the virgin Si(1 1 1) sample shows that the surface roughness is significantly enhanced. However, the roughness is not strongly dose-dependent within the range of doses (2×10^{15}–2.15×10^{16} Co/cm^2) studied. The oscillations on the reflectivity curves arise from the interference due to scattering from a carbon layer deposited on the surface during implantation. The thickness of this layer is determined from the periodicity of these oscillations. Independently, we have determined the thickness of this carbon film and the depth distribution of Co atoms by Rutherford backscattering spectrometry[13]. Detailed analysis of the Co-implanted system will be published elsewhere.

X-ray reflectivity from a multilayer system has been worked out by Parrat[5]. For the multilayer system each interface can be represented by a Gaussian of the form given in eq. (6), with σ_l representing the rms roughness of the $(l-1)$th interface. (The first layer being vacuum, σ_2 represents the roughness of the surface of the second layer or the first interface.)

We believe that now with the availability of this powerful technique in India, further activities will be stimulated in the fast-developing area of surface and interface physics.

Single-ion activities by a solid ion transmitter bridge and a reference electrode without liquid junction

S. Parthasarathy and K. Ramya

Centre for Electrochemical and Energy Research, SPIC Science Foundation, 110, Mount Road, Madras 600 032, India

It had been shown that it is possible to measure thermodynamic values of single-ion activity using a solid ion conductor to bridge a reference electrode and a test electrode, thus eliminating liquid junction potentials. This led to redefinition of activity of an ion and brought out into sharp focus the crucial role of the charge factor in determining the effective strength of an ion. In this paper, we have measured potentials, free from liquid junction, using chloride ion sensors and the solid-ion transmitter bridge for determining chloride ion activity in zinc chloride solutions, leading to confirmation of definition of activity of an ion already proposed.

THE central paradigm of the theory of ionic solutions of strong electrolytes can be stated as follows:

1. It is impossible to measure the activity of single ion in solutions of strong electrolytes, as any reference

electrode will have to necessarily form a liquid junction with the test solution[1,2].

2. Liquid junctions potentials cannot be eliminated, but can at best be minimized using devices like a salt bridge[3,4].

3. The concept of individual activity coefficients cannot be defined accurately, and such coefficients may not even be determined experimentally without some supplementary definition of nonthermodynamic nature[5].

Harned[6] has expressed the point at issue in explicit terms: 'We are confronted with interesting perplexity that it is not possible to compute liquid junction potentials without a knowledge of individual ion activities, and it is not possible to determine individual ion activities without an exact knowledge of liquid junction potentials. For the solution of this difficult problem, it is necessary to go outside the domain of exact thermodynamics'. Correlating the liquid junction potentials and individual ionic activities, Guggenheim[7] has deduced equations for cell potentials with liquid junction that are free from ionic activities and concluded that the activity coefficient of a single ionic species is not an operational concept and is completely unnecessary for an adequate treatment of the thermodynamics of the cell with liquid junction. Conversely, this type of cell can furnish no exact information regarding the activity of a single ionic species, whereas the meaning and usefulness of single ion activities have been stressed by Bronsted *et al.*[8], MacInnes[9] and Kortum[10].

Single-ion activity (SIA) would be a prerequisite for building electrochemical potential series without invoking arbitrary zero potential for the standard hydrogen electrode. Measurement of SIA would provide a tool for direct measurement of free metal ion concentration for studies on metal–ligand interactions instead of the fitment procedure adopted currently, using only ionic strength and pH, by successive iterations to calculate the activity of the species in solution.

Thermodynamic activities of the electrolyte can be obtained from the potential of an electrochemical cell without liquid junction. For example, in the cell Zn, $ZnCl_2$/AgCl, Ag system consisting of Zn electrode and an indicator electrode, Ag/AgCl in the same solution is treated as a cell without liquid junction and thermodynamic activities are derived from cell potentials.

The activity of an ionic species is arbitrarily defined as the product of molality and activity coefficient. If SIA can be determined experimentally, this arbitrary assumption can be dispensed with, by comparing it with value calculated using molality and the single-ion activity coefficient (calculated using Debye–Huckel equation and its modifications)[11–13]. This would enable us to check whether the present mode of calculation of SIA will require any modification about which reservations have already been expressed[14].

It has already been shown[15] that the activity of an ion in a solution of molality m may be redefined as the effective strength of the ion expressed by the term $Z^2_i m\gamma_i$ (where Z_i is the valence of the ion), rather than the effective concentration signified by $m\gamma_i$. EMF measurements of the cell Zn/$ZnCl_2$(m)/bridge/KCl(satd), AgCl/Ag have been carried out for different concentrations (molality) of zinc chloride, using a bridge based on solid silver chloride ionic conductor to avoid liquid junction potential. From the experimental data the activity of zinc ion has been derived for different molal concentrations of zinc chloride and has been found to compare well with the calculated values.

This paper presents a new approach to eliminate liquid junction potential by using a solid ion transmitter bridge for determining single-ion activities (chloride ion) in zinc chloride solutions. The experimental results lend further support to the new definition of activity of an ion proposed earlier[15]. The preparation and other details of the solid ionic conductor bridge are also discussed in this paper.

The chloride-ion-selective electrodes are the Ag/AgCl electrodes prepared by dipping a loop of high-purity silver wire into molten high-purity silver chloride. These electrodes are then tested against saturated calomel electrode (SCE) for reproducibility and stability in the cell Ag/AgCl, KCl(satd), Hg_2Cl_2/Hg. Electrodes with a microcapillary tube supplied by Tacussel Electronique, France, were found to be most suitable. The potential is independent of the activity of chloride ions as the cell reaction

$$Ag_2Cl_2 + 2Ag \rightleftharpoons 2Hg + 2AgCl$$

involves only solid substances, and is found to be 0.0456 V (ref. 16). The electrodes were found to attain equilibrium potential faster than thermal or thermal electrolytic electrodes[17]. The zinc electrodes were specpure zinc rods supplied by Johnson Matthey, UK, sleeved by glass tube, fixed with epoxy with 1 cm length of rod exposed, which is amalgamated with distilled mercury. The procedure for preparation of zinc chloride solutions and the experimental set-up used is the same as described elsewhere[15].

Solid AgCl was used to make solid ion transmitter because of its unique plasticity characteristics. For this purpose, pure AgCl was melted into a bridge in the form of a 'U' tube made from pyrex glass with a capillary of 2 mm bore diameter so that it is a uniform solid on par with rolled or cast AgCl sheet or rod. The tubes are put in the furnace maintained at 380°C and held at this temperature for 10 h and then allowed to cool slowly. This will eliminate porosity, cracks and fissure formation and maintain continuity of the solid chloride between the two tips of the bridge.

The bridges were subjected to:

1. *Pressure test.* On application of gas at a high pressure from a nitrogen cylinder, there was no pressure drop, thereby confirming that there are no crevices, leaks or cracks in the solid AgCl.

2. *Electrochemical test.* The measured potential of the cell Ag/AgCl, KCl(satd)/Bridge/KCl(satd), Hg_2Cl_2/Hg was 45.6 mV in accord with expected value.

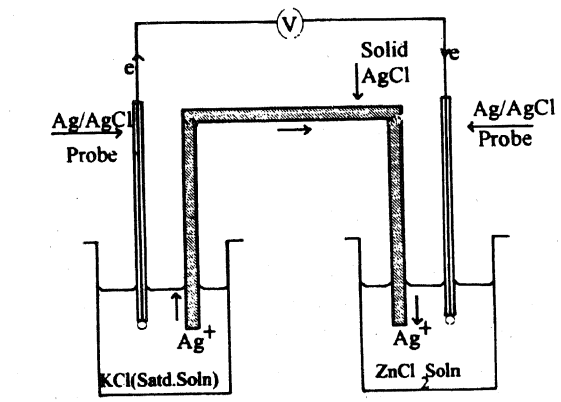
3. *Creep test.* One arm of the bridge was placed in saturated KCl solution and the other in $AgNO_3$ solution. No turbidity or precipitate of AgCl was found even after 24 h. It was also found that the potential-measuring capability is not affected when we switch over from saturated KCl to $ZnCl_2$ (0.1 m) solution as shown in the experiment. These tests confirm that there is no creep of Cl^- ions from one cell to another.

A potential of 1000 V was applied across the two ends of the bridge by connecting to a DC power source and at a point 1 cm away from tips by fusing a Pt wire. The current was in the picoampere range and there was no precipitate of AgCl formed when the bridge was dipped in $AgNO_3$ solution; the potential was applied for several hours. No evolution of gas (chlorine or hydrogen) was observed, thus ruling out the possibility of corrosion reactions. The conductivity of AgCl is 3×10^{-8} mho/cm.

It is noteworthy that the potentials do not vary irrespective of whether a thin bent sheet of rolled AgCl or a glass tube filled with cooled molten AgCl is used. Therefore, the question of creep of KCl through capillary crack or glass tube will not arise. Solid AgCl bridge cannot, therefore, be considered as an equitransferent bridge like KCl.

The activity of zinc chloride electrolyte was determined by measuring the potential of the cell without liquid junction between the Zn electrode and a Ag/AgCl electrode in $ZnCl_2$ solution, i.e. the cell $Zn/ZnCl_2(m)/AgCl/Ag$.

The activity of the chloride ion was obtained by measuring the potential of chloride-ion-responsive electrode in the respective zinc chloride solutions against the Ag/AgCl reference electrode of fixed potential of 0.199 V (ref. 18), i.e., the potential of the cell



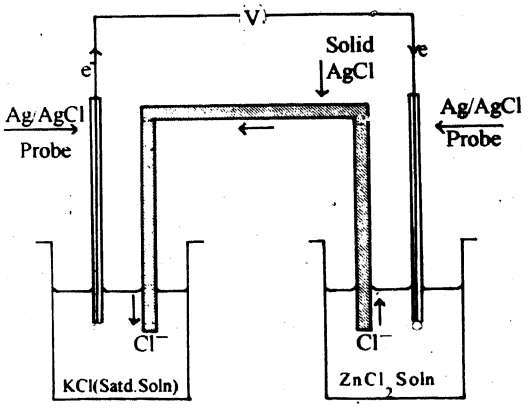
Ag/AgCl, KCl(satd)/Bridge/$ZnCl_2$(m), AgCl/Ag.

AgCl has high ohmic resistance; and it is, therefore, necessary to use a voltage-measuring instrument of very high input impedence for handling singals from high-resistance sources, with negligible IR drop. The instrument used for this study was ORION expandable ion analyser, model no. EA 940, from ORION Research Inc., USA.

It is more convenient to measure the difference in potentials between the various $ZnCl_2$ solutions as the impedences of the two solutions are closer. The experiments carried out for this purpose involve measurement of potentials of the following cells:

1. Ag/AgCl, $ZnCl_2$ 0.1 m/bridge/$ZnCl_2$ 0.01 m, AgCl, Ag.
2. Ag/AgCl, $ZnCl_2$ 0.1 m/bridge/$ZnCl_2$ 0.001 m, AgCl, Ag.

The AgCl-based bridge is best described as a solid-state ion conductor. If the current in the picoampere range is carried entirely by Ag^+ ions, the schematic will be as in Figure 1 *a*, which is in keeping with the normal assumption that Ag^+ ion is the migrant ion in solid AgCl[19,20]. If chloride is to be considered, the reaction schematic can be visualized as in Figure 1 *b*. In any case both the schemes are equivalent. The actual studies on the electromigration of ions is beyond the scope of this paper. But the fact remains that without liquid junction the bridge is able to establish contact between the reference and the test solutions. Further, the instrument used for



$Ag + Cl^- \rightarrow AgCl + e^-$ (Probe)

Observed	$a_{Zn^{2+}}$	0.0998	0.0212	0.0032	ref. 14
By textbook method	$a_{Zn^{2+}}$	0.0252	0.005	0.00077	$a_{ZnCl_2}/a^2_{Cl^-}$

$E_{Ag/AgCl}$, KCl(satd) = 0.199 V; $E^0_{Ag/AgCl} = 0.2224$ V.

measuring the potentials has an input impedence of $10^{12}\ \Omega$. Being a solid-state device and the mechanism clearly a Grotthuss type of conduction of the ion inside the bridge, the requirement that the transference number of conducting ion should be unity will not arise.

A membrane potential cannot be associated with AgCl, as it can by no means function as a membrane. AgCl, being ionized in the solid state, will not permit absorption of either negative or positive ions.

Table 1 presents the potentials measured to calculate the activity of the electrolyte and the chloride ion.

For the cell $Zn/ZnCl_2(m)/AgCl/Ag$, the reactions are:

$$Zn \rightarrow Zn^{2+} + 2e^- \quad (1)$$
$$2AgCl + 2e^- \rightarrow 2Ag + 2Cl^- \quad (2)$$
$$Zn + 2AgCl \rightarrow Zn^{2+} + 2Cl^- + 2Ag$$

Following the IUPAC convention, the cell potential e_1 is given by

$$e_1 = E^0_{Ag/AgCl} - E^0_{Zn/Zn^{2+}} - (RT/2F)\ln[a_{ZnCl_2}]. \quad (3)$$

The electrolyte activity for different concentrations calculated from the e_1 values are given in Table 2. The activity values are in close agreement with those reported earlier[21–23].

For measuring the chloride ion activity, a liquid-junction free solid ion transmitter was used to bridge the reference half cell and the half cell comprising the test solutions. The cell set-up used was:

$Ag/AgCl$, $KCl(satd)/bridge/ZnCl_2(m)$, $AgCl/Ag$.

As the liquid junction potential is zero, following IUPAC convention, the potential e_2 of the cell is given by

$$e_2 = E^0_{Ag/AgCl} + (RT/F)\ln(1/a_{Cl^-}) - E_{ref}.$$

If we denote, $E_2 + E_{ref}$ as e_3,

$$a_{Cl^-} = \text{antilog}\,[(0.2224 - e_3)/0.05916].$$

Equation (3) can be split as

$$E_1 = E^0_{Ag/AgCl} + (RT/2F)\ln 1/a^2_{Cl^-}), \quad (4)$$

$$E_1 = E^0_{Ag/AgCl} - (RT/2F)\ln a_{Cl^-}, \quad (5)$$

$$E_2 = E^0_{Zn/Zn^{2+}} + (RT/2F)\ln a_{Zn^{2+}}. \quad (6)$$

In a completely dissociated strong electrolyte system like MA_2, e.g. $ZnCl_2$, there is an inherent asymmetry arising out of the charge factor, the cation being doubly charged and the anion being singly charged. It is this asymmetry that is reflected in the Nernst equation appropriate to the anion, which can reflect only the activity of each dissociating fragment. In terms of the electrolyte molality m, the molality of cation is m and that of the anion will be $2m$. Then the question arises as to whether which of these two factors 'charge' or 'total molality' is relevant to arrive at the ionic activity. If the charge factor is ignored in Cl^- ion, the activity of the chloride ion will be $2m\gamma_-$ and will contribute a $(2m\gamma)^2$ term in the expression for the activity of the electrolyte. On the other hand, if charge is the factor to be reckoned with, the chloride ion will contribute only $(m\gamma_-)^2$ term to the expression for the activity of the electrolyte.

Table 2. Activities of $ZnCl_2$ electrolyte

Concentration (m)	0.1	0.01	0.001
Activity	5.017×10^{-4}	1.462×10^{-6}	2.89×10^{-9}

Table 3. Difference in potential measured against reference solutions at 25°C

Description	Symbol	Data		Remarks
Molality	m	0.01	0.001	
Cell potential (V)				
Ag/AgCl, $ZnCl_2$, 0.1/$ZnCl_2$(m), AgCl/Ag	e_4	0.055	0.111	
Ag/AgCl, Cl^- electrode	e_5	0.3451	0.4011	$e_4 + 0.2901$

Table 4. Calculation of electrolyte activity

Currently used method	New method proposed
$a_{ZnCl_2} = a_{Zn^{2+}} \times a_{Cl^-} \times a_{Cl^-}$	$a_{ZnCl_2} = a_{Zn^{2+}} \times a_{Cl^-} \times a_{Cl^-}$
$= m\gamma_+ \times 2m\gamma_- \times 2m\gamma_-$	$= 4m\gamma_+ \times m\gamma_- \times m\gamma_-$
$= 4m^3\gamma_\pm^3$	$= 4m^3\gamma_\pm^3$

Clearly, the current definition of activity of an ion as a product of its concentration m and the activity coefficient needs to be revised as the experiments show that the activity is the same as the effective ionic strength defined as $(Z_i^2 m)\gamma_i$ (ref. 15), where Z_i is the valency of the ion.

Table 3 represents the difference in potentials between the chloride-ion-responsive probes in different $ZnCl_2$ solutions. Ag/AgCl, $ZnCl_2$ (0.1) has been used as reference solution with an electrode potential of 0.2901 V (ref. 15). These results confirm the activity of the chloride ion obtained using Ag/AgCl electrode in saturated KCl as the reference electrode shown in Table 1.

The activity of the zinc ion in $ZnCl_2$ solution can be obtained from the activity of the electrolyte and activity of chloride ions, i.e.

$$a_{Zn^{2+}} = a_{ZnCl_2} / a_{Cl^-}^2 .$$

This is found to be in close agreement with our earlier measurement[15] of activity of zinc ion using solid ion transmitter bridge. In the case of zinc ion in $ZnCl_2$ solutions, the charge factor assumes greater importance, and, if activity is treated as the product of the ionic strength of the zinc ion and its activity coefficient, the expected value for the zinc ion will be $4m\gamma_+$. The results of measurements of zinc ion activity using solid ion transmitter is in agreement with the value of $4m\gamma_+$.

The activity of the electrolyte calculated using the current definition to activity of ion and the new definition proposed leads to $a_{ZnCl_2} = 4m^3\gamma_\pm^3$. This is just an accidental coincidence and would not be the case with all electrolytes.

Bates[14] in his recent review on single-ion activities covering a period of 75 years has concluded that individual ion activities are not amenable to thermodynamic measurements. However, in this paper we have shown that liquid junction potentials can be eliminated, thus paving the way for thermodynamic analysis of single-ion activity, overcoming the impasse highlighted by Harned[6].

Fall of liquid drops through a viscous medium: A fresh expression for drag force by the method of dimensions

G. J. Srinivasan and P. Satyanarayana
Forensic Sciences Department, Mylapore, Madras 600 004, India

An attempt has been made afresh by the method of dimensions to get a fresh expression for the drag force F arising from the motion of a liquid drop not exhibiting oscillation through a viscous medium, assuming that the drag force F is a function of D, u, σ, η and ρ alone (D, diameter of the drop; u, terminal velocity acquired by the drop; σ, density of the liquid in the column; η, viscosity of the column liquid; ρ, density of the liquid drop). This paper also relates to the experimental verification of the fresh drag force expression obtained in the case of a liquid drop with fairly high Reynolds number (20–305), Eotvos number (2×10^{-2} to 105×10^{-2}) and Morton number (4.75×10^{-12} to 3.75×10^{-7}) falling without oscillation through an immiscible liquid medium. Furthermore, the experimental value of the constant in the fresh drag force expression presented in this paper is found to be 3.6094.

SEVERAL authors have conducted studies on the fall of solid spheres[1–5] and liquid drops[6–30] through a viscous medium. So far, to the authors' knowledge, none has dealt with the problem of fall of liquid drops with only six variables, F, D, u, σ, η, ρ, in the dimensional analysis of drag force F. Therefore, an attempt has been made afresh to get a fresh expression for the drag force when the drops fall freely without oscillation with these six variables by dimensional analysis. Furthermore, an attempt has also been made with falling drops of fairly high Reynolds, Eotvos and Morton numbers to determine the value which the fresh drag force expression presented in this paper predicts for the constant K by experiment.

In general, there are at least six dimensionless groups that govern the motion of a drop, namely, $\pi_1 = F/D^2u^2\sigma$, $\pi_2 = \eta/\sigma uD$, $\pi_3 = \rho/\sigma$, $\pi_4 = \eta/\eta_0$, $\pi_5 = \gamma/Du^2\sigma$, $\pi_6 = u^2/gD$, where γ is the interfacial tension, D is the equivalent diameter of the drop and g is the acceleration due to gravity. η_0 is the viscosity of the drop. In general, the shape of the drops need not be spherical. The experimental work shows that for sufficiently small drops which appear to be ellipsoidal in shape over the range of Reynolds number $Re = 20$–305 ($Re = \sigma uD/\eta$), Eotvos number $Et = 2 \times 10^{-2}$–105×10^{-2} ($Et = g(\rho - \sigma)D^2/\gamma$), and Morton number $Mo = 4.75 \times 10^{-12}$ to 3.75×10^{-7} ($Mo = g\eta^4(\rho - \sigma)/\sigma^2\gamma^3$) the following simplification holds good:

$$\pi_1 = \phi(\pi_2, \pi_3) = K(\pi_2, \pi_3)^{1/2}, \qquad (1)$$

r = radius of the liquid drop; u = terminal velocity of the drop; ρ = relative density of the liquid drop; σ = relative density of the liquid in the column; η = viscosity of the liquid in the column; γ = interfacial tension between the liquid drop and the liquid in the column.

where K is a constant and π_2 is the reciprocal of the Reynolds number Re and $\pi_3=\rho/\sigma$, the ratio of the densities. Subsituting the values of π_1, π_2, and π_3 in eq. (1), the expression for drag force is

$$F = KD^2u^2\sigma(\eta/\sigma uD)^{1/2}(\rho/\sigma)^{1/2},$$

or

$$F = KD^{3/2}u^{3/2}\eta^{1/2}\rho^{1/2}. \quad (2)$$

Since at the terminal velocity

$$F = 4\pi r^3(\rho - \sigma)g/3, \quad (3)$$

where r is the radius of the drop and is equal to $D/2$, we get the constant K as

$$K = \sqrt{2}\pi g(r/u)^{3/2}(\rho - \sigma)/3\eta^{1/2}\rho^{1/2}, \quad (4)$$

or the terminal velocity u as

$$u = (2\pi^2g^2r^3(\rho - \sigma)^2/9\eta K^2\rho)^{1/3}. \quad (5)$$

Rewriting eq. (4), we get

$$[(r/u)^{3/2}(\rho - \sigma)]/[\eta^{1/2}\rho^{1/2}] = 3K/\sqrt{2}\pi g, \quad (6)$$

i.e. $$\sqrt{2}\pi g\, S/3K = 1, \quad (7)$$

where

$$S = [(r/u)^{3/2}(\rho - \sigma)]/[\eta^{1/2}\rho^{1/2}]. \quad (8)$$

Equation (8) is of vital importance, in the sense that it can be used to determine the density (ρ) of liquids available in microquantities when the conventional methods fail. S has been found to be approximately a constant for all systems (see Table 3), the mean value of which is 0.248319 m^{-1} s^2.

Equation (8) may be written as a quadratic equation which gives the value for ρ as

$$\rho = \{2\sigma + \lambda + [\lambda(\lambda + 4\sigma)]^{1/2}\}/2, \quad (9)$$

where

$$\lambda = S^2\eta/(r/u)^3. \quad (10)$$

Equation (9) may be employed to determine the density of liquids available in microquantities.

A graduated cylinder (diameter 5 cm) filled with the experimental liquid was used. Liquid drops of known volume were gently injected into the liquid column using a graduated Hamilton precision microsyringe. The drops and the liquid were immiscible. The terminal

*The constant of eq. (6)
†S of eq. (8)

velocity u was determined by noting the time of transit t required by the liquid drop of radius r to cover a distance S between two graduations on the column. The drops studied here while falling are ellipsoidal in shape. If V is the volume of the drop of equivalent radius[7] r, then $r = (3V/4\pi)^{1/3}$.

The densities of the liquids were determined accurately by the specific gravity bottle method (Table 1). Viscosity values were determined by using the Ostwald viscometer (Table 1) and interfacial tension values have been determined by the method of drops (Table 1).

Twenty-one liquid systems were studied (Table 1). Only seven liquid drop pairs having three data points each are presented to show that r/u is approximately constant (Table 2). The other fourteen liquid drop pairs for which experimental results have been obtained satisfy the same. The right-hand side of eq. (6) is a constant. A graph is drawn with $(r/u)^{3/2}/\eta^{1/2}$ along the X-axis and $\rho^{1/2}/(\rho - \sigma)$ on the Y-axis (Figure 1). The slope of the line in the graph gives the value of $\sqrt{2\pi g/3K}$.

Substituting the experimental value (0.248319) obtained by eq. (8) (Table 3) on the left-hand side of eq. (6), the value of K can be determined. The value of K thus determined (Table 3) is 3.6109, and that determined from the graph (Figure 1) is 3.6079, the mean being 3.6094. Therefore, for the motion of a liquid drop falling freely and vertically, and not exhibiting oscillation, through an immiscible liquid medium of fairly high Reynolds, Eotvos and Morton numbers, eq.(2) is the fresh drag force expression, in which the experimental mean value of the constant K is 3.6094.

Equation (5) with $K = 3.6094$ may be used to predict the terminal velocity of the drop falling without oscillation. Using eq. (8) (with mean experimental value 0.248319, Table 3), if the terminal velocity and radius are known, one can determine the density of a micro-quantity liquid drop for which the density cannot be determined by the capillary tube method (where weighing is a problem) or by any other conventional methods.

Antibody response to a potentially protective antigen in human filariasis

Madhusmita Bal and Manoj K. Das

Parasite Immunology Division, Regional Medical Research Centre (ICMR), Nandan Kanan Road, Bhubaneswar 751 016, India

Antibody isotype (IgG and IgM) levels to a high molecular weight antigen (1.56×10^5 kDa) isolated from water-insoluble components of *Setaria digitata* were determined to be highly elevated in microfilariae-negative individuals of a *Wuchereria bancrofti* endemic area of Orissa, India. The highest IgM response was found in endemic normals. The prevalence of antibodies was minimum in microfilaraemic group and maximum in endemic normals of the population.

LYMPHATIC filariasis is one of the most prevalent parasitic diseases, estimated to have infected 78 million people globally. In India alone about 45 million people are infected primarily by *Wuchereria bancrofti*[1]. It is a chronic debilitating disease of humans initiated by infective bites of mosquitoes *Culex quinquefasciatus*.

Much attention has been focused recently on the concept of protective immunity in filariasis[2,3]. Various models of animal filariasis indicate that protective responses can be induced by exposure to live or irradiated parasites[4,5]. However, very little is known about protective immunity in human filariasis and there is no direct evidence that such immunity exists in humans. On the other hand, epidemiological studies indicate that age-related microfilarial rates increase and then decrease in older-age classes of endemic population[6]. A proportion of adult residents remain amicrofilaraemic despite intensive exposure to infective larvae (L_3) of filarial parasites. Such disease-free adult residents (endemic normals) are believed to have developed protective immunity to filarial infection. It is presumed that host protective immunity might be effective against the acquisition of (new) infection. Identification of antigens associated with the resistance to infection under natural conditions will be of great importance in deciphering the complex mechanism of filarial protective immunity. In the present report we describe a high molecular weight antigen of *Setaria digitata* which stimulates increased antibody responses only in amicrofilaraemic individuals. Moreover, the IgM response to this antigen is considerably elevated, especially in endemic normals compared to infected individuals.

The study population is from *Wuchereria bancrofti* infected village, Baniatangi (Khurda district, Orissa), about 45 km away from Bhubaneswar, Orissa. Individuals were classified into different clinical groups, namely asymptomatic microfilaraemics (AS), filariasis with chronic pathology elephantiasis and/or hydrocele (CP) and endemic normals (EN) as described earlier[7]. In a random survey of 318 people (age 3–75 years) in the village, AS and CP patients constituted 15.09 and 13.20% of the population, respectively. No attempt was made to include individuals with acute filarial symptoms (adenolymphangitis). Disease-free microfilariae (MF) negative adults (≥ 18 years, 21.83%) were regarded as endemic normals of the region.

Setaria digitata adults were collected from cattle in the local slaughterhouse. Aqueous-insoluble materials were obtained as a pellet by centrifuging the extracts of worms following homogenization and sonication in saline. The pellet was solubilized in the detergent NP-40 (0.5% NP-40 in 0.01 M Tris–HCl, pH 8.0) by keeping for 2 h at 25°C with occasional shaking. The extract was centrifuged again and ammonium sulphate (50%) was added to the supernatant, which was kept at 4°C overnight. The precipitate collected after centrifugation was dissolved in water and was dialysed against phosphate-buffered saline PBS (0.01 M phosphate, 0.15 M NaCl, pH 7.2). The dialysed material upon Sephadex G-200 column chromatography resolved into a major peak (designated as $DSSd_1$) with a molecular mass of 1.56×10^5 kDa, eluted after the void volume, followed by a minor peak.

Pooled sera were made by adding equal volumes of serum from individuals ($n = 40$ in each category) belonging to different categories of bancroftian filariasis. A control serum pool was also prepared from 20 residents of a nonfilarial region (Koraput district) of Orissa and was used as a nonendemic (NEN) sample. Levels of serum antibody to $DSSd_1$ were measured by ELISA using 96-well polysterene plates. The wells were coated by incubation at 37°C (5 h) and then 4°C (overnight) with antigen (3 μg/ml) in bicarbonate buffer (pH 9.6). Next, the wells were blocked with 0.4% bovine serum albumin (BSA) at 37°C (1 h), then incubated (3 h) with diluted serum samples in Tween-20 (0.1% in phosphate buffer saline (PBS)). Final incubations were performed for 1 h at 37°C and 4°C (overnight) with peroxidase-conjugated rabbit anti-human IgG or IgM (Dakopatts) diluted to 1:1000 in 0.1% Tween-20, followed by colour development using orthophenylenediamine substrate. Absorbance was read at 492 nm using an ELISA plate reader (Bio-Rad).

Figure 1 depicts the antibody levels to $DSSd_1$ in different dilutions of pooled sera. It can be seen clearly that AS serum among the filarial groups exhibited the lowest antibody response. Both EN and CP sera had high antibody levels. IgM levels were highest in EN serum, while CP serum had highest levels of IgG. Antibodies in control NEN serum were found to be negligible at 1:400 dilution. IgM and IgG levels of individual sera were determined (Figure 2). The mean antibody values and the extent of sero-positivity (prevalence) are shown in Table 1 and Figure 3.

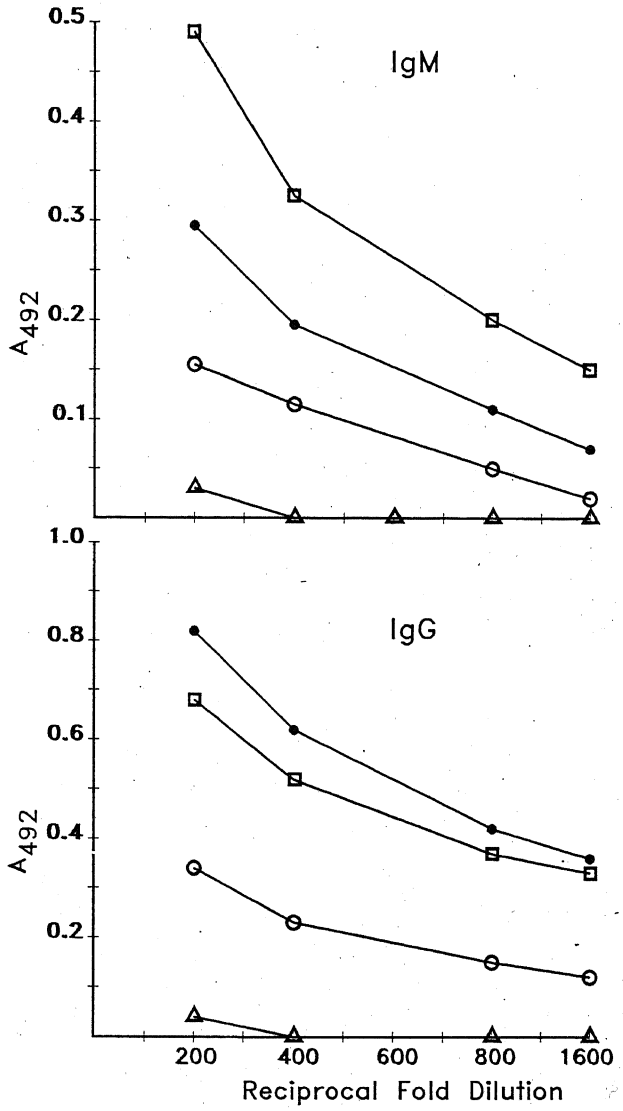

Figure 1. IgM and IgG antibody levels to $DSSd_1$ in pooled filarial sera: chronic filariasis (•); asymptomatic microfilaraemic carriers (o); endemic normals (□) and nonendemic normals (Δ).

The prevalence of $DSSd_1$-specific antibodies in filarial groups was evaluated (Figure 3). IgG and IgM prevalence in AS group is low; only 27.5 and 10%, respectively. The prevalence of these two isotypes in EN is 75 and 85% and in CP 100 and 32%, respectively. All individuals in CP are IgG-positive but only 32% of CP patients have IgM antibodies. EN as a group have the highest of prevalence for both isotypes.

An interesting approach to study the protective immunity is to analyse the immune response of endemic normal ('immune') individuals *vis-à-vis* infected persons. Endemic normals can be assumed as putatively immune since they fail to acquire a detectable parasite burden (MF load and/or filarial symptoms). Such an approach has led to the identification of a 43 kDa larval antigen that is recognized only by endemic normals of a

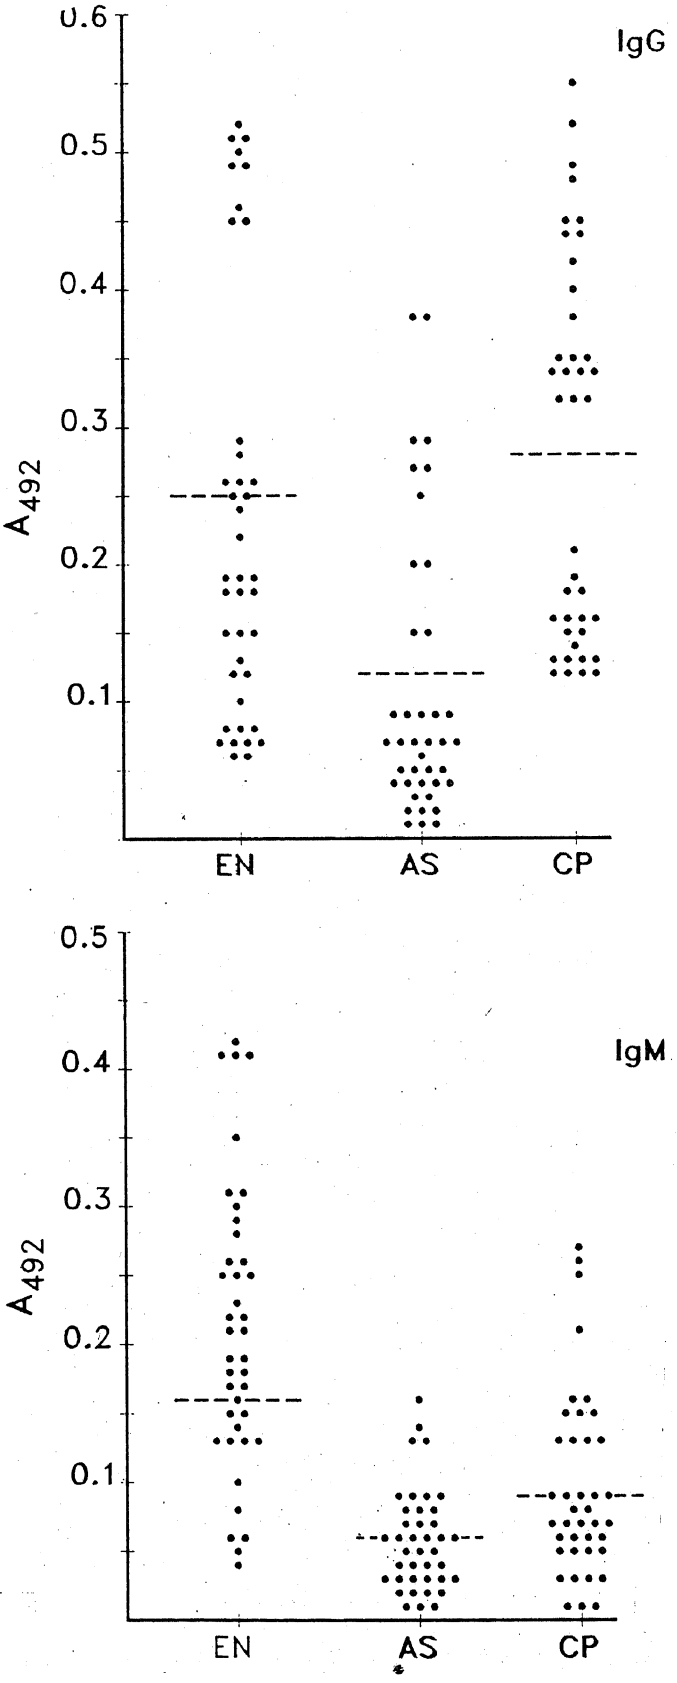

Figure 2. IgG and IgM levels to $DSSd_1$ antigens in filarial sera. The horizontal bar indicates the mean values.

Table 1. ELISA analysis of $DSSD_1$-specific antibody response. Each sample ($n = 40$ in each filarial group) was tested in triplicate (at 1:400 dilution)

Group	IgM		IgG	
	OD 492 (range)	Percentage positive (+ n)	OD 492 (range)	Percentage positive (+ n)
Endemic normals	0.16 ± 0.08* (0.03–0.41)	85 (34)	0.25 ± 0.16* (0.07–0.51)	75(30)
Asymptomatic microfilaraemic	0.06 ± 0.03 (0.01–0.14)	10(4)	0.12 ± 0.10 (0.01–0.38)	27.5(11)
Chronic filariasis	0.09 ± 0.06** (0.01–0.27)	32.5(13)	0.28 ± 0.14* (0.12–0.58)	100(400)

*$P < 0.01$ compared to asymptomatic microfilaraemics.

**$P < 0.01$ compared to endemic normal.

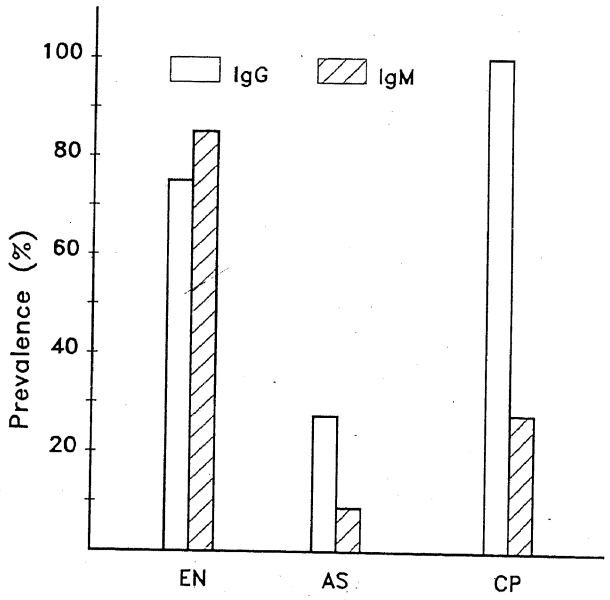

Figure 3. The prevalence of antibodies to $DSSd_1$ in filarial endemic region. Isotypic seropositivity was calculated at 1:400 dilution with respect to nonendemic normals (> mean + 3 SD; n=20). The number of sera in each filarial group was 40.

filarial endemic region[8]. Similarly, in schistosomiasis, infection-free individuals have higher levels of antibodies to paramyosin than the infected persons[9]. Interestingly, paramyosin has also been shown as a protective antigen in *B. malayi* infected animals[10,11]. Several other filarial antigens with protective potential have been identified and characterized[12–14], but studies on human immune responses are limited.

Two notable findings of the present report are: (1) the depressed antibody responses to $DSSd_1$ in microfilaraemic carriers AS group and (2) the elevated antibody response in EN, even higher than in the CP group. This is also reflected in antibody prevalence, which was found to be low in AS, rising to higher values in amicrofilaraemics EN and CP groups. These observations become more marked in comparison to NEN individuals (Figure 1) and suggest that the antibody response that was measured here is specific to filarial infection. The antigen $DSSd_1$ was isolated from the aqueous-insoluble materials of filarial parasite which are normally discarded. In this sense this antigen might constitute an hitherto undetected novel target.

The presence of increased antibody levels in amicrofilaraemic individuals gives rise to the possibility that $DSSd_1$ antigen could be a target of antimicrofilarial immunity in the course of natural infection.

Visual demonstration of *in vivo* acid phosphatase activity of VA mycorrhizal fungi

J. C. Tarafdar
Central Arid Zone Research Institute, Jodhpur 342 003, India

For nondestructive and visual demonstration of the release of acid phosphatase by vesicular–arbuscular (VA) mycorrhizal fungi, filter papers treated with a mixture of 1-naphthyl phosphate as substrate and the diazonium salt Fast Red TR as an indicator were used. Wheat (*Triticum aestivum* L.) was grown for 6 weeks in sterilized soils in specially designed pots with five compartments with or without hyphal and root barriers. Plants were inoculated with *Glomus mosseae* (Nicol & Gerd) Gerd & Trappe and the treated filter paper was placed at the outer surface of the hyphal compartment. Acid phosphatase activity was visualized as a red-coloured 'hyphal print' on the filter paper.

PHOSPHATASE activity in the rhizosphere may originate from the plant roots[1], from fungi such as *Aspergillus*[2], ectomycorrhizas[1] or from bacteria[3]. Vesicular–arbuscular (VA) mycorrhizas are widespread in soils, and their beneficial effect on plant growth in P-deficient soils is attributed to uptake and translocation of P by external hyphae[4]. VA mycorrhizal storage of polyphosphates in the hyphae has also been reviewed[5]. Our recent study indicated[6] the production of phosphatase by external hyphae. Here a nondestructive method for the visualization of acid phosphatase activity by VA mycorrhizal fungal hyphae is described.

A special Plexiglass pot (Figure 1) comprising of five compartments, a central one for root growth, two adjacent compartments separated from the central compartment by a nylon net of 30 μm mesh size, for growth of VA mycorrhizal hyphae (hyphal compartments), and two other compartments, separated by a 0.45 μm membrane, through which neither roots nor hyphae could penetrate, has been described by Tarafdar and Marschner[6]. It was modified by placing a Plexiglass barrier (2 cm × 2 cm) between hyphae and outer compartment on one side of the pot to prevent hyphae to pass into that side. Wheat plants (cv. Star) were grown in sterilized soils of Bavendorf under controlled conditions. The soil used was a cambisol of pH 6.9 and sieved (2 mm) prior to sterilization (48 h each at 120°C, on two alternate days). Water was supplied directly into the root compartment using PVC tubes with string wicks inserted in bottles containing sterilized distilled water.

The mycorrhizal fungus used was *Glomus mosseae*. Each pot received about 1500 surface-sterilized (with 0.2% chloramin T and 0.02% streptomycin sulphate) infective propagules of 90–250 μm in size. The inoculum was mixed uniformly with the whole soil, under aseptic conditions, and added to the central (root) compartment of the pots. Wheat seeds were surface-sterilized and planted, four plants in each pot, into the root compartment. The top openings of all compartments were covered with 2 cm layer of sterilized quartz sand. All operations were performed in a laminar flow chamber. The pots were then transferred to a growth chamber (25–18°C and 15–9 h day–night regime, 305 μmol m^{-2} s^{-1} photon flux density).

For demonstration of phosphatase activity the method used for determination of acid phosphatase in blood serum has been modified by soaking filter papers with the reagents. In this method enzymatic hydrolysis of 1-naphthyl phosphate at pH 5.6 liberates 1-naphthol which reacts with the diazonium salt Fast Red TR (diazotized 2-amino-5 chlorotoluene 1,5-naphthalene disulphonate), forming a red dye. The suitability of 1-naphthyl phosphate as a substrate for phosphatase activity from plant tissues was tested[1] with acid phosphatase isolated from wheat germ.

For the assay the following solutions were prepared – citrate buffer: trisodium citrate solution (50 mM), adjusted to pH 5.6 with HCl (1 M); substrate solution: 37.5 mM 1-naphthyl phosphate sodium salt in citrate buffer; Fast Red TR solution: 2.7 mM Fast Red TR solution in citrate buffer. The substrate solution and the Fast Red TR solution were mixed in a ratio of 1:10 (v/v) and poured into a Petri dish. After soaking in filter papers in the assay mixture for some seconds, they were placed on Plexiglass and the excess solution was removed with paper tissues.

The impregnation and air drying of the filter papers should be carried out in a fumehood to prevent the inhalation of toxic volatiles and also to accelerate the drying process. Thereafter, a 5 mm margin of the filter papers is cut off, as it contains higher concentrations of reagents than the remaining filter paper. The filter papers should be prepared no longer than 2 days before application and stored by wrapping in an aluminium foil in a desiccator. Ashless filter paper (Blue ribbon, No. 589, Schleicher & Schüll, Dassel/Germany) was used.

For the visualization of acid phosphatase activity the pots were opened and the outer compartments separated, and an impregnated filter paper was placed on the surface of the mesh outside the hyphal compartment on both the sides (Figure 1). All the tests were carried out in the growth chamber at 25°C. The filter papers were removed after different times of application and dried.

Acid phosphatase activity by VAM hyphae is visualized as dark red (black on the photographs) 'hyphal print' on the test papers (Figure 2 *b–c*). All parts of the hyphae produced a more or less intensive hyphal print. When hyphae were not allowed to pass by introducing a block, no hyphal print in that area could be

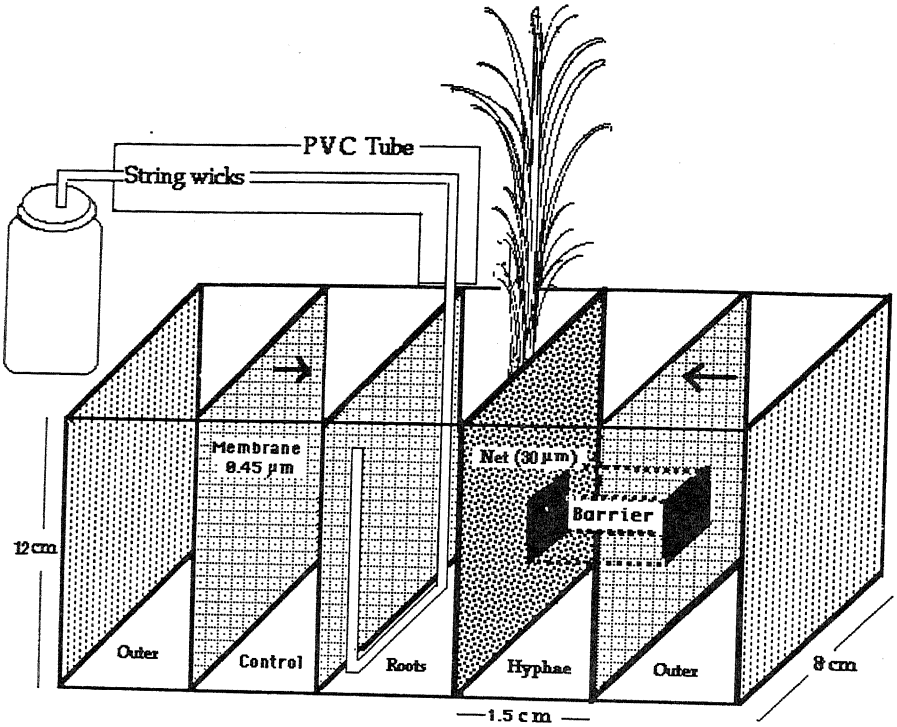

Figure 1. Details of the pots used in the experiment (modified after ref. 6). Arrow denotes the position where the filter paper was put.

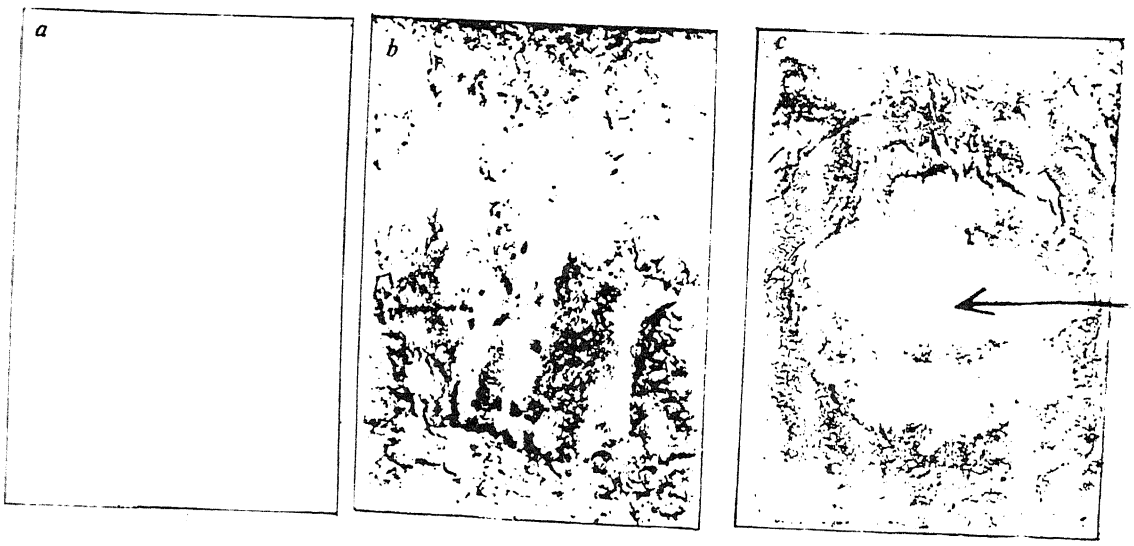

Figure 2. Fingerprints of VA mycorrhizal hyphae: *a*, control; *b*, +VAM; *c*, +VAM with barrier. Arrow denotes the position where the barrier was put on the hyphal path.

seen (Figure 2 *c*). Similarly, no impression was noticed in control (uninoculated pots, Figure 2 *c*). Therefore, these hyphal prints mainly originated from the activity of hyphal surface phosphatase. The dark colour indicates a high phosphatase activity of these hyphal zones. As expected, the intensity of the colour of the hyphal prints depends on the duration of application. Application for only 10 min resulted in a faint, not well-differentiated colouration, whereas it got intensified gradually, with maximum intensity showing when exposed for 60 min.

Acid phosphatase activity in plant roots and soils is usually measured with *p*-nitrophenyl phosphate (pNPP) as the substrate. Since the end product, *p*-nitrophenol is soluble, spraying the filter paper with an alkaline solution at the end of the application period may result in diffusion of the dye and the formation of blurred hyphal prints. In contrast, 1-naphthyl phosphate results in an insoluble end product when no detergent is used. Thus, sharp hyphal prints appear on the filter paper. In addition, the method with 1-naphthyl phosphate has the advantage that the reaction between 1-naphthol and Fast Red TR takes place at low pH. Since acid phosphatases are characterized by maximal activities at low pH values[7], the method with 1-naphthyl phosphate permits a direct and continuous measurement of acid phosphatase activity at its optimal pH.

While 1-naphthyl phosphate is frequently used for the detection of acid phosphatase in medical media[7], only a few reports exist on the use of this substrate for the determination of acid phosphatase from soils[8,9] and from plant roots[1,9]. *In vitro* assay with acid phosphatase from wheat germ also shows that 1-naphthyl phosphate is a very suitable substrate. The present experiment confirmed the production of phosphatase by VA mycorrhizal hyphae. The method may be used for the comparison of phosphatase activity of different VA myocorrhizal hyphae as well as plant species or genotypes in relation to their capacity to utilize organic phosphorus depending upon plant age, phosphorus nutritional status, temperature and other environmental factors.

In vitro flowering and pod formation in cauliflower (*Brassica oleracea* var. *botrytis*)

Vandana A. Kumar, Atul Kumar and Jitendra Kumar

College of Forestry and Hill Agriculture, G.B. Pant University of Agriculture and Technology, Hill Campus, Tehri Garhwal 249 199, India

Flowering and pod formation *in vitro* were induced in cauliflower through culture of curd explants in Murashige and Skoog medium supplemented with 3.0 mg l^{-1} indole acetic acid (IAA) and 0.5 mg l^{-1} kinetin after incubation under 16 h photoperiod at 28 ± 2°C temperature during the day and 24 ± 2°C during the night at a light intensity of 3000 lx. Pods were ready to harvest within 90 days of culture initiation and developed small, globular, smooth and brown-coloured seeds. This phenomenon, though gives small amount of seeds, may be helpful when pollination and fertilization *in vivo* are difficult. This way, the long period for flowering and pod formation under field conditions is cut short and the problem of isolation distance in cross-pollinated crops (like cauliflower) is also overcome.

BREEDING programmes in cauliflower rely mainly on raising seed crops and, under field conditions, proper isolation distance between varieties is necessary for hybridization. Besides, curding and flowering are also very sensitive to changes in temperature[1]. Initiation of flowering and complete pod formation *in vitro* may become a valuable research tool for plant breeders ensuring seed purity. This can also facilitate hybridization *in vitro* without any requirement for isolation distance. A protocol for *in vitro* flowering and pod formation in cauliflower is described.

Florets of 1 cm diameter were excised from a mature curd of cauliflower (snowball-type), surface-sterilized with 70% (v/v) ethanol for 90 s, followed by commercial bleach (calcium hypochlorite) solution (5%, w/v) containing 0.1% Tween-20 for 15 min. After three rinses with sterile distilled water, small (approx. 3 mm cubic) pieces of curd surface were dissected and implanted in the

Table 1. *In vitro* plantlet regeneration in cauliflower

Treatment (mg l^{-1})	Rooting after 30 days		Plantlet formation after 30 days
	No. of roots	Length of roots (cm)	No. of developed leaves
IAA 0.5 + kinetin 0.5 (A)	3.4 ± 0.4	1.8 ± 0.4	Thin leaves
IAA 1.0 + kinetin 0.5 (B)	7.5 ± 0.6	3.6 ± 0.5	2.6 ± 0.4
IAA 3.0 + kinetin 0.5 (C)	14.8 ± 2.3	7.8 ± 0.7	5.7 ± 0.5

culture medium, which consisted of Murashige and Skoog[2] macro- and micro-nutrients, vitamins, sucrose (3%, w/v), phytagar (0.3%, w/v) and different combinations of indole acetic acid (IAA) (0.5, 1.0 and 3.0 mg l^{-1}) with kinetin (0.5 mg l^{-1}). The pH of the medium was adjusted to 5.7. Fifteen ml medium was dispensed in 50 ml (2.5 cm diameter) Borosil culture tubes for autoclaving at 1 kg/cm and 120°C for 20 min. Cultures were incubated under 16 h/day photoperiod and 8 h dark period at 28 ± 2°C during the day and 24 ± 2°C during the night at 3000 lx light intensity.

Data on plantlet regeneration, flowering and pod formation were recorded. Ten cultures each in four replications for every treatment were initiated and the data were subjected to statistical analysis.

When curd explants were cultured on MS medium supplemented with different combinations of IAA and kinetin (Table 1), complete plantlets were regenerated within 30 days in treatment B (1.0 mg l^{-1} IAA and 0.5 mg l^{-1} kinetin) and treatment C (3.0 mg l^{-1} IAA and 0.5 mg l^{-1} kinetin). In cultures containing IAA and kinetin each at 0.5 mg l^{-1} (treatment A), only thin leaves were developed and root development was also poor in comparison to the other two treatments.

The phenomenon of complete plantlet regeneration had a bearing on the flowering and pod formation *in vitro* as is evident from the data in Table 2. While flowering initials appeared within 32 days of culture initiation in treatment C along with complete plantlet regeneration, 80 and 45 days were required for initiation of flowering in treatments A and B respectively. Similarly, opening of flowers (40 days) (Figure 1) and complete pod formation (65 days) (Figure 2) were also earlier in treatment C in comparison to treatment B (56 and 95 days, respectively).

By the time complete pod formation was observed in treatments B and C, only flowering initials appeared in treatment A and the medium was also exhausted in culture tubes. Hence, further data on flowering and pod formation are presented with respect to treatments B and C only (Table 3). The number of flowers/plantlets (7.2 ± 0.6) and the length of the flowering stalk (8.6 ± 0.9) were more in treatment C than in treatment B (3.3 ± 0.4 and 4.3 ± 0.4, respectively) after 60 days of

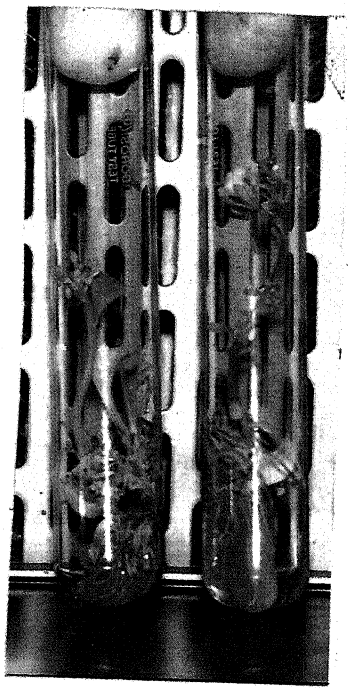

Figure 1. *Left*, appearance of flower initials in treatment B after 45 days of culture initiations; *Right*, opening of flowers in treatment C after 40 days of culture initiation.

Figure 2. Complete pod formation in treatment C after 65 days of culture initiation.

Table 2. Days taken for *in vitro* flowering and pod formation in cauliflower

Treatment	Days taken to		
	Initiation of flowering	Opening of flowers	Complete pod formation
A	80 ± 7.5	—	—
B	45 ± 4.9	56 ± 5.8	95 ± 8.2
C	32 ± 4.3	40 ± 4.8	65 ± 6.2

Table 3. Details of *in vitro* flowering and pod formation in cauliflower

Treatment	No. of flowers/ plantlets	Length of flower stalk (cm)	No. of pods/plantlets	Pod length (cm)	No. of seeds/pod
	(after 60 days)			(after 90 days)	
B	3.3 ± 0.4	4.3 ± 0.4	1.8 ± 0.3	2.1 ± 0.4	—
C	7.2 ± 0.6	8.6 ± 0.9	5.2 ± 0.6	4.8 ± 0.4	4.6 ± 0.5

culture initiation. Similarly, the number of pods/plantlets (5.2 ± 0.6) and the pod length (4.8 ± 0.4) were also more in treatment C than in treatment B (1.8 ± 0.3 and 2.1 ± 0.4, respectively) after 90 days of culture initiation.

After 90 days, shedding of leaves and other floral parts was observed in treatment C and pods were ready to harvest. After harvesting, on an average 4.6 ± 0.5 seeds were counted in treatment C only (Table 3).By this time, pods in treatment B were green andimmature.

The *in vitro* developed flowers were typical of cruciferous family, having 4 sepals, 4 petals, 6 stamens, of which 2 were short, and 2 carpels with superior ovary. The seeds in the fruit (siliqua) were small, globular, smooth and dark brown in colour.

Flowering has also been induced *in vitro* under appropriate conditions through culture of thin cell layers of epidermal tissues excised from flowering stems of tobacco and potato[3]. It is hypothesized that the amount of native gibberellins present in the plant appears to be a deciding factor in whether a plant would remain vegetative or bolt and flower[4]. The effect of gibberellins and other growth retardants on *in vitro* flowering of vegetative apex of Japanese pear has also been reported[5]. In our study, *in vitro* flowering in cauliflower through culture of curd explants appears to be under the control of different hormonal regimes, i.e. 3 mg l^{-1} IAA and 0.5 mg l^{-1} kinentin in MS medium.

Though *in vitro* pollination and fertilization gives a small amount of seed, plant breeders can exploit this phenomenon when this is difficult *in vivo*[6]. Further, the problem of isolation distance is also overcome and the long period for flowering and pod formation under field conditions is considerably cut short this way.

Testosterone biosynthesis in triploid sterile male tilapia

R. Koteeswaran, S. G. Sheela and T. J. Pandian

Department of Genetics, School of Biological Sciences, Madurai Kamaraj University, Madurai 625 021, India

Histochemical localization of strategically important steroid dehydrogenase (3β-HSD) and immunohistochemical studies using testosterone antisera confirmed the active nature of triploid interstitial cells and the presence of 5-ene and 4-ene pathways leading to the biosynthesis of testosterone in the testis of triploid sterile tilapia. Hence, the partial sterility suffered by triploid male tilapia is not due to the lack of steroid hormone involved in spermatogenesis.

TRIPLOIDY has been induced by subjecting freshly fertilized eggs to thermal (heat[1] or cold[2]), pressure[3], electrical[4] or chemical[5] shock; in these shocked eggs the extrusion of second polar body has been suppressed as evidenced by the metaphase-spread preparations. Triploidy is also known to result in complete sterility in females (e.g. rainbow trout[6], tilapia[7]), and partial sterility in males (e.g. rainbow trout[6], tilapia[7]). The partial sterility suffered by males has generally been attributed to endocrine and cytological incompatibilities, although no

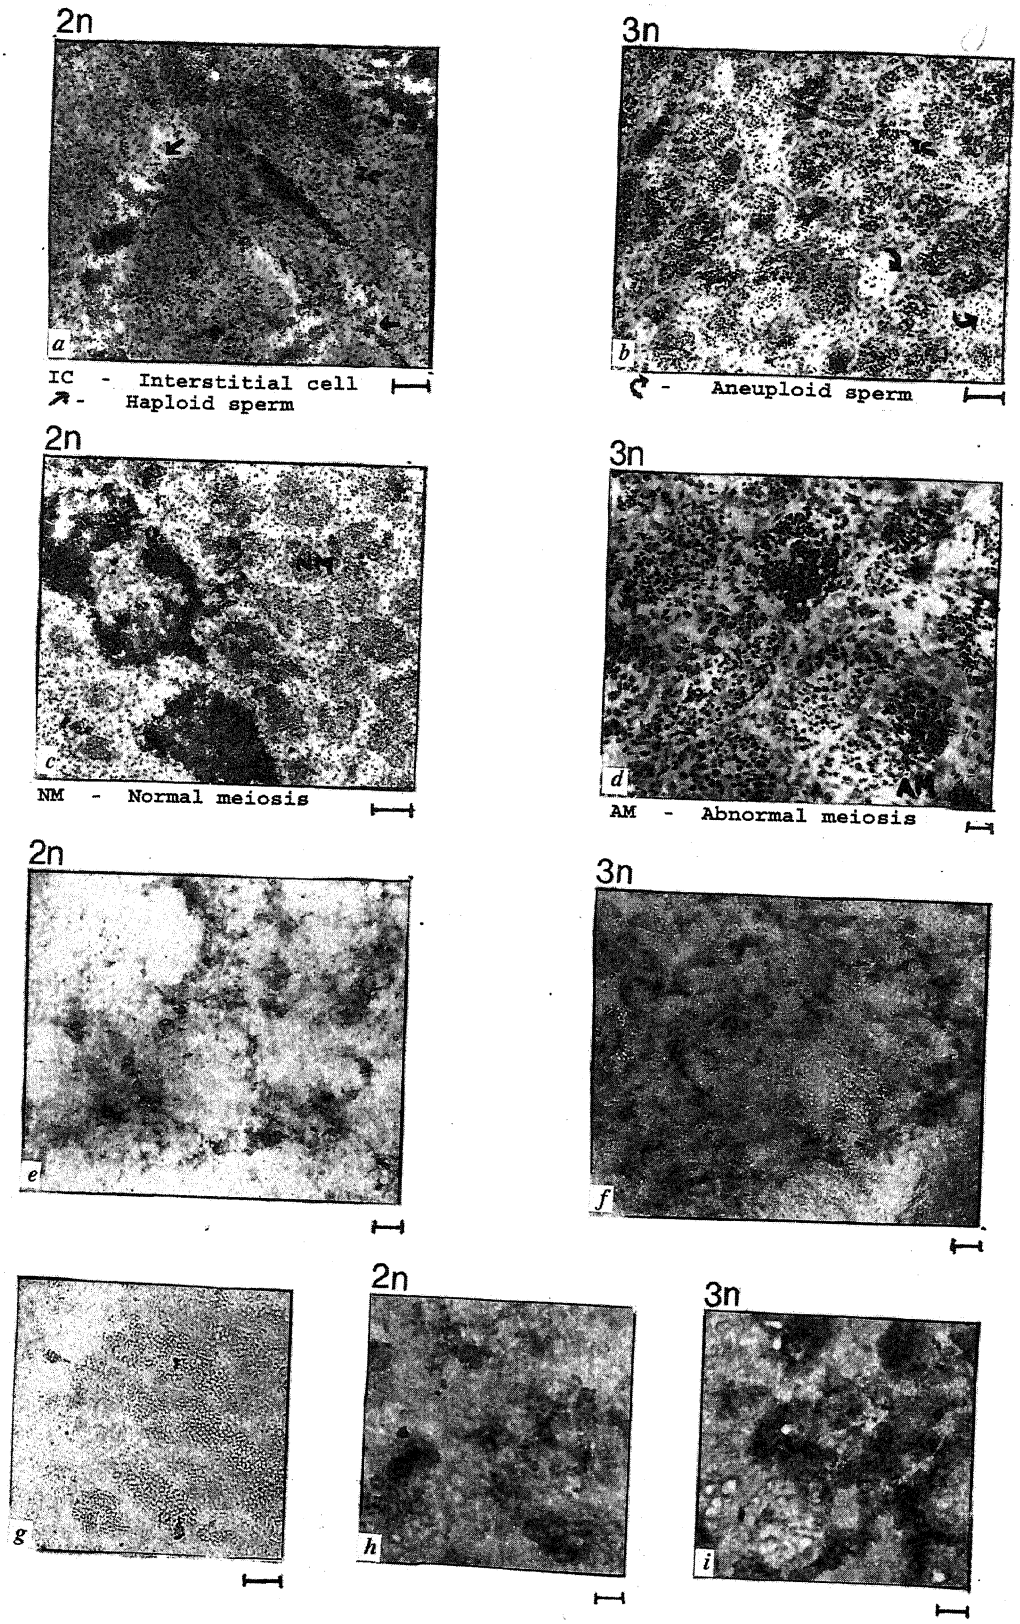

Figure 1 *a–i*. Selected sections of diploid ($2n$) and triploid ($3n$) tilapia. Bar = 5 μm.

direct evidence has so far been reported. Lincoln and Scott[6] were perhaps the first to show the occurrence of testosterone in the partially sterile male triploid *Oncorhynchus mykiss* using radioimmunoassay. This observation has been subsequently confirmed in the same[8] and *Perca flavescens*[9]. This communication reports the occurrence of strategically important hydroxy steroid dehydrogenase, which indicates that the partial sterility suffered by triploid male tilapia is not due to the lack of steroid hormone involved in spermatogenesis.

Triploidy was induced in *Oreochromis mossambicus* following the procedure described by Varadaraj and Pandian[10]. These triploids were reared until they attained sexual maturity. Testes from confirmed triploids were sectioned in a cryotome (International Equipment, USA). H-E staining was done to obtain the structural details. Fresh frozen sections (16 μm) were incubated in an appropriate incubation medium for 2–3 h according to the method of Baillie *et al.*[11]. Pregnenolone was selected as a substrate for histochemical localization of 3β-HSD. The incubation medium contained 0.1 M sodium phosphate buffer (pH 7.2), 0.14 mM pregnenolone, 0.6 mM nitro blue tetrazolium and 7 mM NAD. The sections were fixed in 10% formalin after the completion of reaction. Immunohistochemical staining was done according to the method of Kuhlmann[12]. Sections (16 μm thick) were first neutralized of their endogenous peroxidase activity by treating with 1% hydrogen peroxide in PBS. To reduce nonspecific staining, sections were blocked using normal goat serum and 1% BSA. This was followed by incubation with testosterone antisera (Sigma, USA, in 1:10 dilution of the reconstituted lyophilized stock) for 2 h at room temperature. Finally, sections were treated with 1:100 dilution of HRP-coupled goat antirabbit IGg (Genei, Bangalore) for 1 h and developed in a solution containing 30 mg 4-chloro-1-naphthol, 10 ml methanol, 30 μl of 30% hydrogen peroxide and 40 ml of 1 × PBS for 15 min in dark. After each treatment the sections were washed thoroughly with PBS (pH 7.2) to remove the unbound protein molecules from the sections.

H–E staining of the testis of 5-month-old triploids revealed the presence of numerous interstitial cells as in diploid controls (Figure 1 *a*, *b*). Their active nature was confirmed by lipid and histochemical staining. There were a few irregular-sized spermatozoa in triploid testis, indicating their aneuploid nature arising due to abnormal meiosis (Figure 1 *a*, *d*). In contrast, the diploid sections showed the presence of abundant, regular-sized spermatozoa (Figure 1 *a*, *c*). The 3β-HSD activity was slightly stronger in the triploid interstitial cells (Figure 1 *f*) than that of the diploids (Figure 1 *e*). Control sections incubated in substrate-free medium showed no reaction. Testosterone immunoreactivity was slightly stronger in the triploid sections (Figure 1 *i*) than that in the diploids (Figure 1 *h*). Control sections incubated in substrate-free medium showed no reaction (Figure 1 *g*). Hence, the triploid interstitial cells are active and produce testosterone through the 5-ene and 4-ene pathways.

Hyder *et al.*[13] observed an increase in the plasma testosterone titre in correlation with an enlargement of interstitial cells when human chorionic gonadotropin was administred. Hence, the presence of larger interstitial cells in triploid tilapia might be due to their active involvement in testosterone biosynthesis.

Conversion of pregnenolone to progesterone is a key step in the formation of all biologically active steroids. As 3β-HSD brings about this conversion, its activity has been used to confirm the interstitial cells[14] and is also considered as a measure of steroid biosynthesis by many workers[15,16]. The stronger activity of this enzyme in triploid interstitial cells indicates the presence of highly active 5-ene and 4-ene pathways in triploids. Stronger immunohistochemical staining for testosterone confirms the conclusion.

In conclusion, the triploid interstitial cells and the 5-ene and 4-ene pathways leading to the biosynthesis of testosterone are active. The partial sterility suffered by triploid male tilapia may be attributed to the problems in meiosis, and not due to the lack of steroid hormone involved in spermatogenesis.

Ethnobotany and the Search for New Drugs. (Ciba Foundation Symposium 185, Symposium on Ethnobotany and the Search for New Drugs, Fortaleza, Brazil, 30 November to 2 December 1993). Derek J. Chadwick and Joan Marsh, eds. John Wiley & Sons, Chichester, UK. 1994. pp. 10 + 280. Price: £47.50/$76.00

Ever since the English physician William Withering brought *Digitalis purpurea*, till then part of folk medicine, into Western medicine, plant-based medicines have played a major role in organized healthcare delivery throughout the world. A major step forward in the ascent of plant-based medicines was when, in the last century, Bayer, the German chemical major, decided to synthesize and mass-produce aspirin – a slightly modified form of a naturally occurring compound isolated from willow bark. Aspirin turned out to be the largest sold drug ever! Today more than 25% of prescription drugs issued in North America contain bioactive compounds that are derived from or modelled after plant natural products. Norman Farnsworth of the College of Pharmacy of the University of Illinois at Chicago has identified 119 secondary metabolites isolated from higher plants that are being used globally as drugs. But for awhile, especially after the invention of antibiotics and the development of sophisticated synthetic methods, drug companies relegated the development of plant-based drugs to the backburner. One reason for this temporary disenchantment with plant-based medicines could be the enormous costs involved in testing thousands of plants at random. For instance, the National Cancer Institute of the United States used this approach from the mid-1950s until 1982. The actual yield of this programme is estimated to be one marketable anticancer drug per 8000 plants tested! In the meanwhile drug companies also found the synthetic route – wherein hundreds of compounds are synthesized and tested – to be unaffordable.

It is at this juncture that the enormous potential of ethnobotany came to be recognized. The idea is simple. Instead of testing plants at random, only those plants which are being used by traditional societies to cure their sick will be tested. In other words, one should try to take advantage of folk knowledge. That involves cross-cultural transfer of knowledge. The actual transfer of the plant material from its natural habitat to the drug companies involves transfer of valuable resources. These lead to questions of intellectual property rights, patents and adequate compensation.

Thus, ethnobotany is not mere botany; it is about people, it is about cultures, it is about biodiversity, it is about the possible threats of deforestation, acculturation and wiping out of cultures and natural resources, and it is about multimillion dollar drug business. Above all, it cannot wait. No one knows how long the plants and the cultures which know about their efficacies will survive.

I am sure all these concerns were uppermost in the mind of Paul Alan Cox of Brigham Young University when he suggested the holding of this symposium to the Ciba Foundation. If the resulting book is any indication, the conference must have been organized very well. Some of the leading workers in the field have contributed excellent papers.

The book opens with a brief introduction by Ghillean Prance, Chairman of the Royal Botanical Gardens, Kew. He set the tone for the conference by drawing attention to the interdisciplinary nature of the field, and asking 'What have indigenous people gained from the use of their knowledge by Western culture?' He also drew attention to the problem of translation between the categories (of ailments) adopted by the traditional societies and the categories used in modern medicine. This was followed by 15 presentations; it was rather unfortunate that Richard Evans Schultes, one of the world's leading ethnobotanists, could not make it to the conference. However, his brief but informative paper on Amazonian ethnobotany was circulated and discussed at the conference. Schultes emphasizes the need to intensify ethnobotanical field research to be able to win the race against mindless devastation and destruction of rain forests and acculturation. He ends his paper with the plea that 'all scientists involved make every effort possible to encourage the training of more ethnobotanists and ethnopharmacologists willing to carry on field work with people who still have the knowledge of plants and their properties which they have inherited from generations unnumbered'.

Michael Balick, a student of Schultes, observes that the most valuable contributions of ethnobotany to drug development can come from small and tightly focused programmes, especially with plants used to treat hepatitis, diabetes, diarrhoea, gastrointestinal problems, skin infections, fungi and wounds. In his opinion, it is essential to combine medical and ethnobotanical skills to obtain a proper understanding of plant use in terms of both Western science and traditional beliefs. As we do not know the chemical composition and the full medicinal potential of 99.5% of the plant kingdom, Balick would like drug companies to continue the random approach as well. Indeed, the Institute of Economic Botany, of which Balick is the director, is collaborating with Pfizer in exploring the plant wealth of forests in the United States. Paul Cox, another student of Schultes, has looked at the strengths and limitations of the ethnobotanical approach to drug discovery. He lists more than 50 drugs discovered from ethnobotanical leads. He points out that 72% of every research dollar spent in the Western world is spent on cardiovascular illness, neoplasms, nervous system's disorders and microbial diseases. But very few indigenous cultures have recognized cancer and leukaemia and, therefore, the success rate of ethnobotanical route in the discovery of cancer drugs may not be high. On the other hand, the success rate with regard to gastrointestinal disorders, the most frequent type of disease in Third World countries, may be high.

While emphasizing the need to evaluate plants used as traditional medicines, because more than 3300 million people in the less developed countries use medicinal plants on a regular basis, Norman Farnsworth draws attention to the difficulties encountered in ethnopharmacological work. He warns that unless ethnomedical information is collected in great detail and accurately, it will be no better than random selection of plants followed by targeted biological screening. He pleads for more well-trained ethnobotanists. Farnsworth also gives a brief account of the NAPRALERT database, which provides information on the pharmacological effects of extracts of living

organisms, ethnomedical information on the use of plants, and the biological effects of secondary metabolites.

Walter Lewis and Elvin-Lewis explore the basic, quantitative and experimental research phases of ethnobotany with special reference to the medicinal plants of South America. Search for new drugs cannot succeed unless all the three phases are taken care of. Elaine Elisabetsky and Darrel Posey look at the development of plant-based antiviral compounds, particularly for the treatment of gastrointestinal disorders, based on the experience and practices of Kayapó Indians of Brazil. Another paper based on Brazilian plants, by Craveiro *et al.*, deals with natural products' chemistry. It also describes the Living Pharmacy Programme, under which the local people are taught to cultivate and use medicinal plants correctly. Maurice Iwu, Xavier Lozoya and S. K. Jain have reviewed the current status of African, Mexican and Indian ethnobotanical research, respectively. Iwu has listed several Nigerian plants and their medicinal use; Jain has given lists of Indian plants useful in the treatment of intestinal, joint, liver and skin diseases. Lozoya points out that the lack of clinical studies of plant remedies traditionally used in less developed countries is one reason for the failure to come up with new herbal drugs. Could it be that the Western healers and researchers are threatened by the success of the native epistemology which could, unaided by the tools of Western science, discover and retain the knowledge of plant-based cures for millennia? Does the West suffer from a cultural handicap? In this respect, Asian researchers have an advantage over Western researchers, feels Lozoya.

Pei-Gen Xiao gives an account of ethnopharmacology and new drug development in China. There are 7295 species of plants used medicinally in China, and plant-derived drugs make up 45% of the market. Gordon Cragg and coworkers describe the experience of the US National Cancer Institute (NCI) over the past three decades and more in ethnobotany and drug discovery. A welcome feature is a discussion on intellectual property rights, international collaboration and compensation. NCI collects material from foreign institutions such as the Bogor Herbarium in Indonesia and the Botany Department of the Philippines National Museum.

Two researchers from Shaman Pharmaceuticals, Steven King and Michael Tempesta, describe the company's experience in drug development based on leads obtained from native healers. They have a good team of interviewers assisted by competent translators. Shaman's is one major success story among drug companies using the ethnobotanical route to drug discovery. They already have two drugs, Provir for respiratory viral infections and Virend for herpes, in clinical trials. More are expected. Shaman has a scheme of compensating the native people and communities providing the knowledge.

John Barton, who teaches law relating to high technology at Stanford, discusses the intellectual property rights issues involved in ethnobotany and its use in drug development and manufacture. He pins his hope on nongovernmental organizations to develop a uniform agreement on the relative rights of indigenous peoples and of their governments. Gary Martin looks at the prospects of judicious exploitation of plant resources without harming conservation and biodiversity as well as how ethnobotanists working in the field can help in community development and sustainable plant use. Berlin and Berlin raise questions pertaining to preservation, codification and promotion of traditional cultures and knowledge systems, and returns to the native communities. They narrate their experience in Mexico working with the Highland Mayapeople. The book ends with a brief but perceptive conclusion by Ghillean Prance.

This is an excellent book. It deals with a topic of great current interest and urgency and it has brought together the views and experiences of many of the leading scholars in the field drawn from North America, Europe, Asia, Africa and Latin America. It covers all aspects comprehensively. The conference format has contributed a great deal, as is evidenced by the enormous amount of useful information that has come up in the discussions following each presentation. Indeed, the book would have lost considerably if the discussions were not included. The Ciba Foundation and John Wiley & Sons deserve full marks.

The only flaw in this well-produced book is that some pages shown on the contents page do not match with the beginning pages of the articles.

Environmental Health Perspective; Supplements: Molecular Mechanisms of Metal Toxicity and Carcinogenicity. National Institute of Health, USA. 1994, vol. 102.

Environment Health Perspective is regularly published by National Institute of Environmental Health Sciences, National Institute of Health, USA. This journal regularly publishes research papers, review articles and sometimes status report in certain areas related to environmental health. It also publishes supplements containing lead articles on research work presented at international meetings.

This volume of *Environmental Health Perspective, Supplements* (Vol. 102, Supplement 3, September 1994) contains selected papers from the Second International Meeting on Molecular Mechanisms of Metal Toxicity and Carcinogenicity held in Madonna di Campiglio, Italy 10–17 January 1993.

The field of metal carcinogenesis and metal toxicology is changing at a rapid pace, so much so that it is now being looked into not only at the organism level but also at the molecular level. Selected papers published in this volume deal with several important molecular aspects of toxicity and carcinogenicity, such as oxidative and free-radical effects, genotoxicity, mechanism of resistance, carcinogenetic process, relationship between carcinogenesis and metallothionein, cellular and molecular aspects of toxicity, etc.

The articles of this volume contain interesting data on chromium-cadmium-, nickel- and arsenic-induced carcinogenesis. Data on chromate-induced DNA strand breaks, Fenton-reagent-induced generation, powerful oxidants, and evidences for radical species as intermediates in cadmium/zinc-

metallothionein-dependent DNA damage *in vitro*, etc., have been discussed. A series of studies in this category revealed a central mechanism that damages to the DNA molecule are caused by oxidants induced by various metals and their salts. The DNA damage is related to mutagenic response and genetic toxicity.

In an interesting article, Wang *et al.* from Norton Nelson Institute of Environmental Medicine and the Kaplan Cancer Center of the New York University Medical Center, New York, reports that an arsenic-resistant Chinese hamster cell line shows increased resistance to toxic concentrations of arsenic after pretreatment with a nontoxic concentration. Such an induced tolerance can be completely inhibited by actinomycin D or cycloheximide. Another group from China reports that human fibroblasts are ten times more susceptible to sodium arsenic than Chinese hamster ovary cells. According to epidemiologic studies, arsenic is associated with increased risk for certain types of human cancers, including epidermoid carcinomas of skin, lung cancers, and possibly liver cancers. However, inoculations of inorganic arsenic have failed to induce tumours in most laboratory animals. The paper by Je-Chang Lee throws light on the differential susceptibility between humans and experimental animals to arsenic, indicating a possible mechanism as to why human exposure to arsenic may cause cancer.

Although cadmium is an environmental carcinogen, suspected to cause lung and prostate cancer in humans, the exact mechanism of cadmium carcinogenesis is not known. A low molecular-weight (6000–7000 Da) protein metallothionein is known to protect cells against metal toxicity. Timothy P. Coogan and colleagues of National Cancer Institute, Maryland, suggest that metallothionein gene activity is quiescent in the ventral prostate of mice. This tissue-specific quiescence of the metallothionein gene has been suggested to determine tissue's susceptibility to cadmium carcinogenesis.

Although metallothionein (MT) plays an important role in cellular resistance to metal toxicity, very little is known about the degradation of metallothionein and tumour of the metals bound to it. In an interesting article by C. D. Klaassen and colleagues of the University of Kansas Medical Center, Kansas, it has been reported that lysosomes might be important in degrading metallothionein, and that metal release is a prerequisite for degradation. The order of sensitivity towards degradation is apo-MT >> Sn MT >> Cd MT.

A unique method for fabrication of ultramicrosensors to study metal movement through cell membranes has been described by T. Malinski and colleagues. A number of papers describe the role of various metals in inducing signal transduction mechanisms. Several papers deal with the effects of organometals on cell signalling, effects of low-level dietary supplementation of organic selenium risks arising out of consumption of polluted mussels for lead poisoning, etc.

In general, this volume contains papers dealing with the most up-to-date knowledge in the field of metal toxicity and carcinogenicity, and also with their cellular and molecular mechanisms. Readers would find it quite useful to update their knowledge.

Annual Review of Biochemistry 1994. C. Richardson, ed. Annual Reviews Inc., 4139 El Camino Way, Palo Alto, California, USA. Price: USA $49, elswhere $55. Volume 63.

During the past six decades we have discovered time and again that the excitements in the area of biological chemistry are periodically updated in this series, although its undisputed eminence has been constantly challenged. Part of the answer to the success of this series lies in a set of vibrant articles on contemporary themes published year after year. The current issue comprises 28 chapters describing, in principle, a variety of different and diverse aspects under the general rubric of biochemistry. Of particular interest to the ever-increasing number of practising biochemists is the preparatory overview by Osamu Hayaishi. The *Sensei* in an inimitable fashion recounts the events that led to the discovery and characterization of a class of ubiquitous enzymes called the oxygenases. In a fitting tribute, the chapter on lipoxygenase translates his original ideas into much broader issues of human health and disease processes.

The chapters can be roughly divided into four groups. The major section of this book focuses on myriad components involved in cell signalling. The body of any organism (yes, it applies even to the unicellular microbes!) probably cannot function without the network of chemical signals – hormones, growth factors, lipid molecules, neurotransmitters – that communicate with diverse population of cells. Research in these areas over the years have proved to be a fertile ground for gaining insight into the complexities of biology – and of Nobel prizes. There are two chapters, one on nitric oxide and the other on polypeptide toxins that exist in the venoms of predators. The former, which gained notoriety as the molecule of the year 1993 is believed to participate as a major regulator in a variety of cellular processes and is also alleged to have a role in influencing the sexual behaviour. Bredt and Snyder provide an excellent description of all one would like to know about NO, but is afraid to ask! Olivera *et al* emphasize the utility of a class of small polypeptide toxins from marine snails and spiders as probes for elucidating the architecture of calcium channels and as therapeutic agents. This chapter is very clear, well written and is reader-friendly! The section on membrane receptors by Krieger and Herz provides a useful compilation of a variety of different problems in this broad field of multiligand lipoprotein receptors. However, the author's proposition of a 'unifying concept' of ligand recognition, at present, appears to be a dangerous exercise. The framework of the processes in the classical paradigm involving the interaction of G protein coupled receptors with ligands leading to the activation of a variety of cellular processes – via kinases and phosphatases – such as perception of odours, increase in the intracellular vesicle trafficking or change in the electrical activity of brain cells is illustrated in chapters by Strader *et al.*, Johnson *et al.*, and

Nuofer and Balch. There are over 20 odd G proteins which receive and coordinate signals from more than 300 receptors. Despite this complexity, works in several laboratories have linked abnormal G proteins to pituitary and testicular tumours, cholera, leukaemia and other forms of cancer. These three chapters are complementary and anyone with some basic knowledge should be able to follow the flow of the theme. The gods of science lately have smiled fondly on people who took up this messy and elusive area and made it elegantly crisp. Finally, in recent years contributions from the fields of genetics and molecular biology have led to the explosive growth in the number and variety of steroid/thyroid superfamily of intracellular messengers. Tsai and O'Malley have summarized the current understanding of their action, at the molecular level and have identified the issues for the future.

In the second section several chapters discuss various cellular processes and cytological organelles. These include synaptic transmission, intermediate filaments and centrosome. Bennet and Scheller emphasize largely the role of synaptic proteins in vesicular fusion, while Kennedy discusses the molecular events underlying synaptic transmission. Although these two chapters are written independently, the authors make a valiant effort in speedily bringing the oriented reader up to date but the unfamiliar reader may find it essential to consult some textbooks. Intermediate filaments are responsible for a myriad of housekeeping and specialized functions in multicellular eukaryotes. Fuchs and Weber summarize the recently gained exciting insights into the functions of intermediate filaments and their liaison in human disease. In the chapter on centrosome, Kellog *et al.*, discuss the components and their general organization.

In the third group, three separate chapters deal with different and diverse aspects that fall under the general category of energy transduction. Trumpower and Gennis illustrate the way by which prokaryotic and eukaryotic organisms couple the redox energy available from the reduction of molecular oxygen, while Howard and Rees point out that the study of nitrogen fixation has grown exponentially during the past few decades to accommodate not only bioinorganic chemists and spectroscopists but also microbial physiologists. Hartman and Harpel bring us up to date in the continuing saga of engineering plants with catalytically most efficient Rubisco. Although it continues as a paradigm for protein engineering, even the most modest goal of converting the less efficient bacterial enzyme into the somewhat more efficient plant enzyme has not been achieved. However, as discussed, the contributions from the application of atomic genetic and molecular biological tools have clarified the mechanics of energy transduction. Spectroscopic studies have erroneously attributed a role for a covalently bound form of quinone in several enzymatic functions. Although the intimation of quinones as redox cofactors seems to be correct, the article by Klinman and Mu encapsulates the problems and clarify the status of quino-cofactors in biology.

Molecular recognition is the underlying dictum of all chemical and biological processes from protein folding– and catalysis– to genetic recombination. This theme is best illustrated in a set of articles in this group. There are two articles related to HIV, although a part of it was covered in the previous volume. This bias is perhaps understandable in light of its immense importance in public health. Katz and Skalka's chapter describes retroviral enzymes, in general, that also serve as focal points for designing therapeutic drugs. A more direct emphasis is found in the article by Jones and Peterlin on transcription initiation at the HIV-1 promoter with analogies drawn to the eukaryotic systems. The function of DNA polymerase is discussed (Joyce and Steitz) mostly from a structural point of view and the mechanistic connections are less clear. The article on the regulation of DNA replication by Coverly and Laskey is more fascinating than that of the simple information carrier. Of particular interest in this section is the punchiest article on homeodomain proteins (Gehring *et al.*). The authors give the reader an idea of the rewards when chemists and biologists ultimately speak in the same terms in order to understand a complex developmental circuitary system. Over the last decade a combination of genetic, biochemical and structural studies have revealed a new level of mechanistic details in steps underlying the mechanism by which the integrity and fidelity of chromosomes is maintained. The chapters on DNA repair, single-strand DNA-binding proteins and homologous pairing and DNA strand exchange discuss in general the proteins involved and the mechanisms of these processes. Research in these areas is so vibrant that it is discussed almost every year in this series. Indeed, many of the same approaches originally designed for microbial systems have now been successfully applied to higher eukaryotic systems.

I have tried to find faults with this book and in some cases found them. It is regrettable that plant biochemistry, lipids, carbohydrates and methodology have been largely overlooked. Another shortcoming, albeit minor, is the article on Caulobacter differentiation, which belongs, in my opinion, either to the *Annual Reviews of Genetics* or *Annual Reviews of Microbiology*. Despite this, I consider the book to be a highly useful reference on a compendium of topics of diverse nature, containing up-to-date bibliography and appropriate illustrations; consequently, I rate it a shoulder above other series in this league. If the goal(s) of the authors is to inspire the newcomers to the subject, in most cases, it is certainly realized. I am confident that the 'jewel in the crown' of biological chemistry will shine again!

K. MUNIYAPPA

Department of Biochemistry,
Indian Institute of Science,
Bangalore 560 012, India.

Joseph Needham (1900–1995)

There is a saying in Arabic:

> *Maut-ul-Aalim Maut-ul-Aalam,* the death of a scientist is the end of an epoch. This is indeed true for Joseph Needham, whose depth of knowledge and wide-ranging interests are matched by a few, if any.

Joseph Needham was born on 9 December 1900. His father was a physician, and, according to Joseph, a pioneer in pathological histology who later specialized in anaesthesia. His mother was a musician and composer. He had a comfortable childhood, but showed from the beginning a sympathy for working class and when only 13 years old argued for socialism with his father. He earned a degree in natural science and taught biochemistry at Gonville and Callis College, with which he remained associated all his life. He married Dorothy, also a biochemist. Both became Fellows of the Royal Society. However, by 1930 he got interested in history of science, particularly in history of Chinese science. It was probably his contact with Gwen-Djen Lee, who later became his collaborator in the project on Chinese science and whom he married after the death of his wife Dorothy. Two events shaped the direction of his life's work.

The first one was his participation in the Second International Conference on the History of Science and Technology held in London in 1931. Some of the papers presented by the Russian delegation, headed by N. I. Bukharin, which left a deep impression on English participants were those of Boris Hessen on socioeconomic roots of principia, N. I. Vavilov's paper on the origins of the world's agriculture, E. Colman on crisis in mathematical sciences and B. Zavadovsky's paper on physical and biological factors in the process of evolution.

The English side was represented amongst others by J. D. Bernal, J. B. S. Haldane, Hyman Levy, L. Hogben, Benjamin Farrington, Joseph Needham and others. Each one of them was afterwards to work out social, political and cultural and economic dimension of science in their fields of specialization.

The second important event was his appointment as a counsellor, appointed by the British Council in 1942 to extend Anglo-Chinese relations. As a counsellor he travelled extensively in China, and brought out photographs and a sort of commentary on the contemporary developments in the science and technology in China. This was published in 1945 as Chinese Science. Thus began his appreciation of communist China.

There is a photograph, no. 48, in this book with Joseph on a donkey, along with three Chinese on an edge of the desert city of Yuchyachuan. I am told that here his party was attacked by bandits. While the Chinese despaired of their and Joseph's life. Joseph got down from his donkey and did a Scottish dance, seeing that, the leader of the bandit got down from his donkey and did a dance, after which both the parties went their way.

The book gives a bird's eye view of the organisation and development of scientific research of free China, providing historical insights. In discussing these developments his horizon was not limited. For instance, talking of cave temples of Chienfutung he compares them with the caves of Ellora and Ajanta in India.

Joseph had wide-ranging interests on nearly every aspect of human intellectual, social, cultural and political activities, and he comments on these with his erudition. In his own words he was, a 'prowler and explorer among ideas'. He had his views on science, philosophy, religion, arts, history, but what was significant about these views was that he was always modifying them and evolving his ideas about them in the light of new knowledge. For instance, talking of science and religion he says that his earlier description of science was rather too narrow and the description of religion certainly much too neoplatonic, idealistic, pietistic and otherworldly[1].

Joseph was deeply concerned with the rise of Hitler and its consequences on science. He delivered a lecture at Cornell University in 1940 in which he described its consequences on international science. In doing so he drew upon the historical development of science, to show that Nazi's attempt ran counter to the scientific tradition[2]. An interesting feature of the lecture he showed through statistical data the decline of science in Germany as was evident from publication of papers. He also produced data on scientists of established reputation, who were exiled from Germany, Austria, Czechoslovakia and Italy. In most of his articles, lectures and talks, he touched upon historical, social, cultural, political and philosophical features, and also compared the developments with non-European culture areas. His systematic approach to the study of problem is brought out in his essay: 'Limiting Factors in the History of Science'. It covers nearly every possible dimension starting from the relation of the investigator to his environment, co-operation of investigators, techniques and balance between observation, experiment and speculation.

Apart from being a great scholar, he was, what is now being termed, an activist. He was involved in controversies of the period, as those with A. V. Hill and Michael Polyani on the nature of science and role of scientists. He was also involved in a Committee which examined the germ warfare in Korea, and other causes involving injustice, or hegemonistic politics.

He was greatly concerned with one question, one of 'the deepest historical questions that can be raised'. Why did the body of systematized knowledge and theory about nature which we call science not develop also in India or China?[3]

Later, writing a new foreword to the papers presented at the Second International Congress on the History of Science and Technology (1931) to the second edition published in 1971 he wrote; 'With the appearance on the scene of intensive studies of mathematics, science, technology and medicine in the great non-European civilizations, debate is likely to sharpen, for the failure of China and India to give rise to distinctively modern science while being ahead of Europe for 14 previous centuries is going to take some explaining.'

While he concentrated on writing the history of science in China, he encouraged scholars in India, as well as those in Islamic Culture area, to write histories of science in these countries. Writing to the then secretary of the National

Institute of Science of India (now Indian National Science Academy) in 1954 March he wrote, 'I am profoundly convinced (with Dr. Hora) that urgent steps must be taken to put the whole subject of the history of science and technology in India on a proper basis, furthermore that the later history is perhaps the more promising to start with, pending for the historical researches into the datings of texts of antiquity.'

Six years before his death he had organized a conference, which represented his perspective on non-European societies and scientific developments. Explaining the purpose of this Conference on The Historical Dynamics of Oriental Societies, he wrote to the Secretary of Commonwealth Science Council on 15 May 1984: 'The conference is meant to involve a multisided discussion aimed at bringing about greater and more realistic understanding of the specificity of the histories of societies such as China, India, Japan and the Islamic world'.

While Needham worked and published his books on 'Science and Civilization in China', covering nearly all the different branches of science and technology, along with their social and philosophical dimensions, he gave references to the contemporary developments in Asia, as well as in Europe. For instance, in the second volume on the association between nature-mysticism and science he dealt with European linkages, as well as China, the Islamic world and India (pp. 94–99). In his discussions on Sufism and science in the Islamic world he brought out the social features as well. In mentioning the role of Qaramatians he mentions: 'That an alliance of this kind should have existed between the mystical scientists and the organized workers is not the least surprising. Since, as cannot be too often repeated, the great cleavage lay between those who were prepared to engage in manual operations and those who considered them unworthy of a gentleman. Between techniques and magical recipes there was no wide gap' (Vol. II, pp. 96).

He was the first person to recognize the division between natural Sufism and esoteric Sufism. The reason for the latter lay in the power of the governing elite in the suppression of unorthodox beliefs, turning the mystical system into purely religious and unworldly forms. This happened to Sufism in India.

There are many aspects of his personality which are revealed in various incidents of his life. Two or three are worth recalling.

Joseph was the Chairman of a Committee for the development of a university in Sri Lanka, one of the members of this Committee was Mr. Chatterjee, the then Vice Chancellor of the Rajasthan University, Jaipur. Joseph had asked me to meet him in Jaipur. I called on him and he started discussing with me a few points regarding the history of science in India, while we were discussing, the Vice Chancellor came reminding him about the meeting with the Governor. Joseph got up, went to his room and brought a few books for me to go through. The Vice Chancellor, seeing him carrying the load of books remarked, 'There are always servants to carry things for you'. Joseph retorted, 'I never do that sort of thing'.

While Joseph was master of Gonville & Caius College, he invited me to tea. When I went there, there was no light. Thinking that he was not there, I switched on the light and found Joseph deep in thought. I apologized for disturbing him, in his thinking. His reponse was, 'I was not thinking, but was only rearranging my prejudices.'

Another lesson I got from him was when he gave me a book to read on crusades. I had read in my childhood a book on crusades in Urdu, where Muslims were believers and Christians were infidels. Muslims were brave, generous and great fighters while Christians were just the opposite. The book in English painted the picture in the opposite – Muslims were infidels, weak, and not brave!!

As I remember him I am reminded of an Urdu couplet:

'You who are now going away, you would be long remembered.'

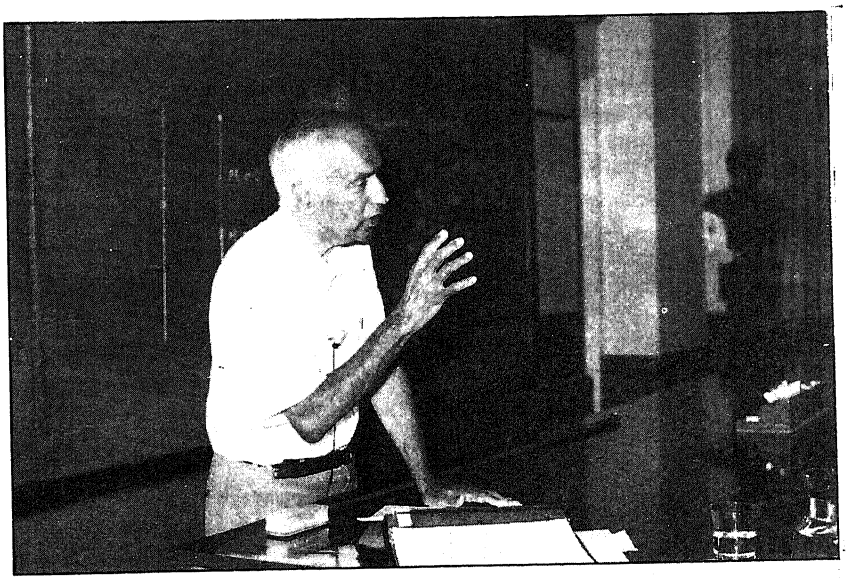
Subrahmanyan Chandrasekhar

R. Nityananda

Subrahmanyan Chandrasekhar, the astrophysicist, died on 21 August 1995 at Chicago, where he had worked at the University for the last fifty-eight years. He would have turned eighty-five on the 19 of October this year. His last book, *Newton's Principia for the Common Reader*, had just been published by the Oxford University Press, the product of his dedicated studies over the last several years. He was in the process of preparing for a lecture and thus died as he always lived – working.

His career can be summarized simply enough – an Honours degree in physics at the Presidency College, Madras (1926–1929), a doctorate (1930–1933) followed by a fellowship (1933–1937) at Cambridge University in England, then a move across the Atlantic to the Astronomy Department at the University of Chicago, which was located at that time at Yerkes Observatory, about a hundred miles from the city. He married his college classmate Lalitha, who survives him, in 1936. His positions at the University started with a research associateship and culminated in the Morton D. Hull Distinguished Service Professorship, which he held from 1952 till he relinquished it in 1986 because 'it is better to leave when everybody asks "Why are you leaving?" than to stay while everybody wonders "When is this guy thinking of retiring?"'.

The list of his scientific contributions makes clear why Chandrasekhar was a legend in his own time. In 1930, fresh from his undergraduate degree, he combined the principles of quantum mechanics and special relativity to calculate the pressure of the electrons in white dwarf stars. The result was dramatic – there was a maximum mass, roughly one-and-a-half times that of the sun, above which a sphere of cold matter sustained only by electron pressure would continuously shrink under gravity, never finding any equilibrium configuration. There were indeed earlier papers which had noticed that these principles imply a maximum mass. A year later, Landau wrote a characteristically brief paper which pointed out the existence of the limit, and went on to speculate, presciently about stars with the density of atomic nuclei, and incorrectly about new physics – energy nonconservation – coming into play. Chandrasekhar's work was distinguished both by mathematical thoroughness and a conviction that the result was of fundamental importance. Strong conviction was badly needed, because Arthur Eddington, the Plumian Professor of Astronomy at the University of Cambridge, ridiculed the final result as an absurdity, claiming that one of the starting assumptions was in error. Since Eddington could not pinpoint the error in a manner acceptable to physicists ('I think there should be a law of nature to prevent the star from behaving in this absurd way'), an impasse resulted which is hard to understand so many years later. The personal relationship between Chandrasekhar and Eddington seems to have continued in spite of these events, and he did spend some years in Cambridge after his doctoral degree, though they could scarcely have been comfortable ones. The astronomy community, at least in the United States, seems to have reacted by accepting Chandrasekhar into its midst, without taking any stand on his remarkable result. His own reaction was probably the most remarkable and ultimately fruitful. He wrote his first book on stellar structure, an exposition of both existing knowledge and his new ideas. The style is so lofty and detached that the reader senses no hint of the skepticism and confusion then prevalent amongst astronomers. With this he bid goodbye to the controversy. The stand he had taken on the existence of a maximum mass – known to everyone else as the 'Chandrasekhar limit' – was ultimately vindicated by subsequent theory and observation. The award of the Nobel Prize of Physics in 1983 was primarily for this work.



At the Golden Jubilee meeting of the Indian Academy of Sciences.

Around the year 1938, he commenced research in a new area, the dynamics of stars moving in clusters and galaxies under their mutual gravitational attraction. The greatest strength of his work on stellar dynamics was the systematic calculation of the effects of 'encounters' between stars in a cluster – not physical collisions but random gravitational scattering by neighbours. He developed a parallel with the theory describing the Brownian motion of a colloidal particle in a fluid. *En passant*, he wrote the standard survey article on the latter subject as well, in the *Reviews of Modern Physics* of 1943. Generations of theoretical physicists, not necessarily interested in stars, have learnt the basics of Brownian motion from this reference. The deepest consequence of this parallel was that, in spite of the apparent randomness of the scatterings, a star must experience a systematic effect tending to bias its velocity to the mean of its neighbours. His name for this effect – dynamical friction – is as much a part of the vocabulary of astrophysics as the Chandrasekhar limit. Such a process is now known to operate not only in clusters of stars but in much larger scale systems as well, e.g. in merging galaxies.

The work on stellar dynamics ended around 1945 – in this one instance he appears to have written his book, which appeared in 1942, before the picture was

complete. His grand strategy was now established. Five years of deep study and calculation and a book now followed, devoted to radiative transfer – the mathematics underlying the emission, absorption, and scattering of photons in the atmospheres of stars and the pattern of intensity and polarization which emerges to enter the telescopes of astronomers. Today, the problem in its most general and realistic form is attacked by massive computation. Even Chandrasekhar's book begins with a discussion of numerical integration. But after this prosaic start comes a *tour de force* – the nonlinear integrodifferential equations of the theory admit an exact solution in special cases, at least after persuasion by the master craftsman. This calculation gave him the greatest personal satisfaction, stemming not so much from impact as from its elegance. A fruitful physical idea underlies this achievement. While the outcome of the totality of the scattering process in a finite slab of material is usually complicated, the change in the outcome caused by adding one more thin layer can be expressed in a simpler form. This 'invariant embedding' principle also carries with it the 'principle of invariance'. When the slab is semi-infinite, addition of one more layer must reshuffle the individual photons in direction and polarization but leave the overall pattern of the radiation the same.

A systematic study and exposition of hydrodynamic and hydromagnetic instability followed in the next decade, and his book on the subject (which has grown greatly since then) is still valued as a clear and readable introduction, especially to certain topics often used in astrophysics. He made incursions into plasma physics as well. But the next topic to which he turned his attention must have surprised everyone. It was the study of self-gravitating rotating masses of a fluid of uniform density. For one thing, the subject was very old, originating in Newton's 'magisterial' (Chandrasekhar's phase) derivation of the figure of the earth. It had already attracted the attention of mathematicians like Jacobi, Riemann, Dedekind and Poincare, to name but a few. Chandrasekhar could see that all was not well here, and in extensive work with Lebowitz, unified and cleared up many aspects, simplifying the mathematics

Lecturing at the Raman Research Institute

and deriving new results on the way. The achievement was distilled as usual into a book, *Ellipsoidal Figures of Equilibrium*. This severely classical area acquired unexpected relevance with the discovery in 1967 of radio pulsars, which were soon confirmed to be rapidly rotating neutron stars. Since dissipation has a subtle effect on the instabilities of these objects, he was led to include in his studies a form of dissipation caused entirely by an effect of general relativity – the emission of gravitational waves. The electrodynamic analogue is the extra resistance encountered when a charge is accelerated, originating in the loss of energy by radiation. This effect was known from the time of Lorentz, but the gravitational analogue, in spite of work by many people – Einstein, Eddington, Landau and Lifshitz – was riddled with conceptual and mathematical difficulties. A series of papers by Chandrasekhar and his students showed the way by developing the so-called 'Post-Newtonian theory' and deriving, systematically, the gravitational analogue of the Lorentz formula for radiation reaction. In the same period, he also discovered an instability of stars against radial pulsation, again a problem where general relativity made a qualitative change. A well-known astrophysicist has remarked that the work of this period could well have become the content of another classic book. But such a book was never written because by this time the author had now come fully under the spell of Einstein's theory of gravitation, and in particular the black holes, which are an inescapable consequence of that theory (and also his own work on the limiting mass). Unlike on earlier occasions, he was a comparatively late entrant into the area. A whole band of 'relativistic astrophysicists', most of them half his age, were already using pencil, paper, and computer to perturb black holes, scatter all kinds of waves off them, immerse them in external fields, and investigate their properties and stability. The year 1974 brought a heart attack and ultimately major surgery was recommended. He consciously put this off till the fall of 1977 so that he could finish a set of papers on the Kerr solution describing rotating black holes. One of his students has remarked that every complication envisaged by medical textbooks occurred after the operation! It is a measure of his inner strength that he recovered to commence writing *The Mathematical Theory of Black Holes*. This book appeared in 1983 and has a rather different character from its predecessors. It represents his personal efforts to present results in the area (including, of course, many of his own) in a framework which appealed to his own sense of scientific style. Even after all his efforts to find rational and simple ways of doing things, literally hundreds of pages of calculations had to be deposited into archives for scholars of the future. The stability of the Kerr solution could not be fully pinned down. Many things can and have been said of his writings starting from this

period. Understandably, he no longer found the time and energy to go through all the voluminous literature, and perhaps even the proofreading was not as meticulous as before. The problems investigated could border on the exotic – e.g. two black holes connected by a cosmic string! He himself cheerfully described this apparent retreat from the astrophysically relevant as 'downhill, all the way down'. But to focus on these aspects alone would be to miss the basic point – he had done more 'relevant' work than all the critics combined, and was now following where his mathematical and aesthetic instincts led him. What was truly remarkable was the spirit in which all this work was done, which can only be described as youthful exuberance. Consider his paper on the complicated wave equations describing the motion of a spinning electron in the gravitational field of a rotating black hole. From the time of Euler, the mark of a mathematical physicist has been the ability to 'separate' such multidimensional problems by reducing them to one-dimensional components. This is because there is no standard route or guarantee of success. Many people in the field would have been happy to separate the Dirac equation in the Kerr spacetime, but Chandrasekhar started and finished the calculation on the same evening! In this phase, he would fly to Houston for a day or stop over at Crete or Rome for a week to discuss his latest ideas with his friends and collaborators. A young postdoctoral fellow arrived unexpectedly in the same week as when his Nobel Prize was announced. Who else could have got down to work nevertheless and had the first manuscript on colliding gravitational waves almost ready in two weeks? His last book, in which he undertook to read Newton's *Principia* from the point of view of a mathematical physicist rather than a Latin scholar, again bears the strong stamp of being guided by personal taste and satisfaction. His lectures on this subject conveyed vividly the sense of wonder and awe that reading Newton in the original gave him.

There is so much that can be said of his scientific achievements (many have been omitted above!) and style that there is a real danger of missing other contributions. During his watchful and uncompromising editorship, lasting nearly two decades, the *Astrophysical Journal* grew from near-provincial to international stature. His teaching and his supervision of research students were legendary. Even though he had collaborated with the likes of von Neumann (on stellar dynamics) and Fermi (on galactic magnetic fields), he always said his deepest satisfaction came from interactions with students and younger colleagues. Many of these matters, including his austere lifestyle and deep literary and musical interests, have been extensively documented by Kameshwar Wali in a biography entitled *Chandra* (the name by which Chandrasekhar was widely known but which this Indian pen finds too familiar to use comfortably).

A topic of special interest would be his relationship with two countries – India, where he was born and spent his formative years, and the USA, where he grew to world stature. It is often felt that here is a clear case of a person not finding proper conditions and recognition in his own country. His anguish when he felt that a good person in India was not given his due, or with the growth of hierarchy and bureaucracy in the Indian scientific establishment, has been well documented, for example in Wali's book. Yet his relationship with India does not end there. He was a founding Fellow of the Indian Academy of Sciences at the age of 24, and had an offer to work at the Indian Institute of Science after his stay in England. A serious effort was made to bring him to India as the Director of the (then) Kodaikanal Observatory, and he seems to have treated it with equal seriousness before declining. He retained his Indian citizenship till 1953. On visits to Bangalore in the seventies and eighties, he not only willingly and enthusiastically delivered lectures but also spent time talking to students and young researchers, offering comments and reactions in his inimitable style. In these encounters, one could detect no trace of the alienation, cynicism or bitterness that some would ascribe to him. Culturally, he had deep affinities with India, as he has recorded in a little known essay 'on being a foreigner'.

Coming to the American side of the coin, the current wave of adulation launched by the Nobel Prize is not typical of the reactions to him in earlier years, when recognition was slow in coming and hard-won. An authoritative collection of classic and influential papers in astrophysics edited in 1979 managed not to include a single one by him. Perhaps this atmosphere which he encountered in his early years might even have spurred him to new heights of labour and achievement. This is not the place to draw any firm conclusion about the complex feelings that he must have had for both nations, but one can certainly discount the more simplistic view of the matter that is usually propagated. In any case, when one looks at the totality of the work, the manner in which it was carried out, and the impact on colleagues, students, and even people who encountered him just a few times, questions of nationality seem to fade into insignificance. What will remain is the memory and the legacy of a man who never stopped learning, thinking and working throughout a long life, and was driven both by his sense of what was right and what was beautiful to heights that very few will ever attain.

On Ramanujan's bust*

S. Chandrasekhar[§]

Ramanujan was elected a Fellow of the Society in 1918 and he died in 1920, slightly more than a year after his return to India in 1919. The story of how a bust of one who had died in 1920 came to be made 60 years later is of some interest; and I hope that it is proper to tell that story on this occasion.

In his biographical note for Ramanujan (*Proceedings of the Royal Society*, **A99**, xiii–xxix), G. H. Hardy wrote:

'It was his insight into algebraical formulae, transformation of infinite series, and so forth, that was most amazing. On this side most certainly I have never met his equal, and I can compare him only with Euler or Jacobi. He worked, far more than the majority of modern mathematicians, by induction from numerical examples: all his congruence properties of partitions, for example, were discovered in this way. But with his memory, his patience, and his power of calculation he combined a power of generalisation, a feeling for form, and a capacity for rapid modification of his hypotheses, that were often really startling, and made him, in his own peculiar field, without a rival in his day.'

In his lectures on 'Ramanujan' at the Harvard Tercentenary Conference of Arts and Sciences in 1936, Hardy reassessed what he had written in 1921 as follows:

'I do not think now that this extremely strong language is extravagant. It is possible that the great days of formulae are finished, and that Ramanujan ought to have been born 100 years ago; but he was by far the greatest formalist of his time. There have been a good many more important, and I suppose one must say greater, mathematicians than Ramanujan during the last fifty years, but no one who could stand up to him on his own ground. Playing the game of which he knew the rules, he could give any mathematician in the world fifteen.'

In more recent times Ramanujan's reputation has been enhanced considerably. For example, the slight overtone of criticism implied in Hardy's remark 'the great days of formulae are finished' has been countered by 'the days of great formulae are not finished'. With respect to the fall and rise of Ramanujan's reputation, Bruce Berndt (the author of five volumes of 'Ramanujan's Notebooks') has compared him to Johann Sebastian Bach, who remained largely unknown for years after his death in 1750. For Bach, the big turnaround came on 11 March 1829 with Felix Mendelssohn's performance of the *St Matthew Passion*. For Ramanujan, the roughly analogous event was George Andrew's discovery of the 'Lost Notebook' in 1976.

And what is this 'Lost Notebook'?

G. N. Watson had worked on Ramanujan's papers for many years before World War II. When Watson died in 1965, The Royal Society asked J. M. Whittaker (the son of E. T. Whittaker) to write Watson's Biographical Memoir. For that purpose, Whittaker had asked Mrs Watson whether he could examine the papers that Watson might have left in his study. There, in Watson's study, as Whittaker recalled:

'... papers covered the floor of a fair sized room to a depth of about a foot, all jumbled together, and were to be incinerated in a few days. One could only make lucky dips [into the rubble] and, as Watson never threw away anything, the result might be a sheet of mathematics but more probably a receipted bill or a draft of his income tax return for 1923. By an extraordinary stroke of luck one of my dips brought up the Ramanujan material.'

This 'material', of some 87 loose sheets, was part of a batch of papers Dewsbury (the Registrar at the University of Madras during the years 1909–1924) had sent to Hardy in 1923 and that had, somehow, wound up with Watson. After his 'lucky dip', Whittaker passed them on to Robert Rankin (Watson's successor in Birmingham), who in 1968 handed the 87 loose sheets mentioned, together with other unpublished material, to Trinity College, Cambridge.

And there it lay in the Trinity archives without anyone's knowledge till George Andrews rescued it. George Andrews, who had worked on problems related to 'mock theta functions' the subject of Ramanujan's last letter to Hardy a few months before he died, came to Cambridge to explore if any related material was available in the Trinity archives. He was thrilled and excited by what he discovered in the 87 loose sheets deposited in the Archives by Rankin.

Andrews told me, at a later time, that when he presented a paper on the "Lost Notebook" at a meeting of the American Mathematical Society, Dr Olga Taussky-Todd, who was chairing the session, said 'The discovery of the "Lost Notebook" is as sensational a discovery for the mathematicians as a complete draft of a tenth symphony of Beethoven would have been to the musicians'.

Let me continue with what Richard Askey has written in this connection:

'These pages [of the Lost Notebook] are not dated, but from internal evidence they were written late in Ramanujan's life, much of it in his last year. Two thirds of the pages deal with basic hypergeometric series and most of this work is significantly deeper than Ramanujan's earlier work on the same subject. Try to imagine the quality of Ramanujan's mind, one which drove him to work unceasingly while deathly ill, and one great enough to grow deeper while his body became weaker. I stand in awe of his accomplishments; understanding is beyond me. We would admire any mathematician whose life's work was half of what Ramanujan found in the last year of his life while he was dying.'

'Some of Ramanujan's work has one quality which is shared by very little other work. Most mathematics, including some very good work, is predictable. Much of the rest seems inevitable after it is understood, and it would

© 1995 The Royal Society.

*Remarks made by the author on the occasion of presenting the bust of Ramanujan to the Royal Society on 11 May 1994.

§ Since deceased

eventually be discovered by someone else. Little of Ramanujan's work seems predictable at first glance and after we understand it there is still a fairly large body of work about which it would be safe to predict that it would not be rediscovered by anyone who has lived in this century. Then there are some of the formulas Ramanujan found that no one understands or can prove. We will probably never understand how Ramanujan found them.'

Let me conclude this part of my story with a quotation from Freeman Dyson:

'The wonderful thing about Ramanujan is that he discovered so much, and yet he left so much more in his garden for other people to discover. For forty-four years I have intermittently come back to Ramanujan's garden; and every time when I come back, I find fresh flowers blooming.'

I now turn to the other strand of the story: how the bust came to be made. It begins with a letter of Hardy's to me.

Hardy was to give a series of 12 lectures on subjects suggested by Ramanujan's life and work at the Harvard Tercentenary Conference of Arts and Sciences in the autumn of 1936. In the spring of that year, Hardy told me that the only photograph of Ramanujan available at that time was the one of him in cap and gown, 'which makes him look ridiculous'. And he asked me whether I would try to secure, on my next visit to India, a better photograph which he might include with the published version of his lectures. It happened that I was in India that same year from July to October. I knew that Mrs Ramanujan was living somewhere in South India, and I tried to find where, at first without success. On the day before my departure for England in October 1936, I traced Mrs Ramanujan to a house in Triplicane, Madras. I went to her house and found her living under extremely modest circumstances. I asked her if she had any photograph of Ramanujan which I might give to Hardy. She told me that the only one she had was the one in the passport which he had secured in London early in 1919. I asked her for the passport and found that the photograph was sufficiently good (even after 17 years) for one to make a good negative and copies. It is this photograph that appears in Hardy's book, *Ramanujan, Twelve Lectures on Subjects Suggested by His Life and Work* (Cambridge University Press, 1940). It is of interest to recall Hardy's reaction to the photograph: 'He looks rather ill (and no doubt, he was very ill): but he looks all over the genius that he was.'

The rest of the story as told by Richard Askey:

'The story of the thread from the "Lost Notebook" to the bust is simple. Andrews has done a lot of very deep work trying to understand what Ramanujan discovered. Eventually the *New York Times* heard about it and interviewed him. *The Hindu* followed with a more extensive interview, and also published an interview with Ramanujan's widow, Janaki Ammal. She lamented the fact that a statue of Ramanujan had never been made, although one had been promised. Andrews sent me copies of these interviews, and after a couple of months my subconscious finally got through to my conscious mind and it was clear that a bust should be made. Since Janaki Ammal was 80, time was important*, so it was up to individuals rather than governments or societies, since institutions move slowly. My first reason for wanting a bust was simple: if Ramanujan's widow wanted one, she should have it. That was the least we could do to show our appreciation of Ramanujan to someone who had been a great help to him.'

'Later I realized there was a second reason, which Janaki Ammal must have realized all along. She knew Ramanujan, and while she did not understand his mathematics, she knew that he was one of the few whose work will last. As long as people do mathematics, some of Ramanujan's work will be appreciated. In Ramanujan's case a more permanent memorial is appropriate; one which can be appreciated by those who do not understand his mathematics should be added to the memorial Ramanujan made for himself with his work.'

From the desire to the accomplishment is a long way.

1. A likeness of Ramanujan had to be found. It was provided by the original of the photograph that is the frontispiece in Hardy's book on Ramanujan.

2. A sculptor who would accept the challenge of making a three-dimensional bust from a two-dimensional photograph. Askey found such a sculptor of distinction in Paul T. Granlund of Gustavus College, Saint Peter, Minnesota, USA.

3. A minimum of four busts had to be commissioned. Askey obtained enough funds by donations from the international community of mathematicians for one bust to be presented to Mrs Ramanujan (which it was in the autumn of 1983). Askey acquired one; and my wife and I two†.

That was how the bust that you see came to be made. And as Askey has said:

'While Granlund does not appreciate Ramanujan's mathematics as those of us who have studied it do, he studied Ramanujan's passport photo deeply, and the results show in the bust. He probably understands some things about Ramanujan that we do not.'

May I now present the bust of Srinivasa Ramanujan to President Sir Michael Atiyah for his gracious acceptance on behalf of the Royal Society.

*Mrs Ramanujan died on 13 April 1994. She was 94.

†Since the original four an additional five have been acquired by other institutions, including the one in the Cambridge Mathematical Faculty Library.

ORISSA BIGYAN ACADEMY

SAMANTA CHANDRA SEKHAR AWARD FOR 1994

(For Oriya Scientists Working Outside Orissa)

The Government of Orissa, Department of Science and Technology, has instituted one Samanta Chandra Sekhar (SCS) Award to be given each year for outstanding research contributions, during the five years preceding the award year, by Oriya scientists working outside the State of Orissa, in any area of (1) physical sciences (2) life sciences or (3) engineering and technology. Persons to be eligible for consideration for this award (a) should be Oriya by birth or domicile, (b) should have passed at least one of the following examinations from any recognized Institution/Board/University in Orissa:

(i) Higher Secondary
(ii) Graduate degree in any branch of science, engineering or technology,
(iii) Postgraduate degree in any branch of science, engineering or technology.

The value of the award is Rs 15,000.00 (Rupees fifteen thousand only) and this is to be awarded through the Orissa Bigyan Academy. Nominations for this award for the Year 1994 are invited from Heads of Research Institutions/Laboratories/Universities/Colleges/Heads of concerned PG Departments in Universities or Colleges in public or private sector, inside/outside the State of Orissa and from SCS Award winners. Nominations from other responsible citizens/government departments may also be considered subject to their acceptance by the Executive Council of the Academy. Five copies of the duly filled-in nomination proforma, along with other particulars stated therein, are to be sent to the Secretary, Orissa Bigyan Academy Type-4R/25, Unit-IX(F), Bhubaneswar 751 007, Orissa (India). The undersigned may please be contacted either by post or in person for obtaining nomination proforma and other particulars. The last date for receiving nominations for this award is 30 December 1995.

Secretary,
Orissa Bigyan Academy
Type-4R/25, Unit-IX(F),
Bhubaneswar 751 007, Tel: 413468.

COUNCIL OF SCIENTIFIC & INDUSTRIAL RESEARCH

NEW DELHI, INDIA.

Advt. No. 8/95

Position: Director, Central Road Research Institute (CRRI), New Delhi

CSIR, the premier agency established by the Govt. of India to undertake scientific and industrial research in the country, is looking for suitable scientist/technologist for the post of Director for its Central Road Research Institute (CRRI), New Delhi. The Institute conducts basic and applied research in the areas of highway engineering and allied subjects, provides know-how for improved and economical methods for construction and maintenance of roads, runways, bridges, etc., and assists the highway user agencies through consultancy, contract research and training. Some of the major R&D programmes of the institute relate to pavement design and performance, road condition monitoring, pavement deterioration modelling, landslide management, hazard mitigation and improved transportation planning for urban areas. In addition, applied research on planning and engineering of rural roads, highway instrumentation, traffic engineering, roads safety and environmental problems form an integral part of the R&D programmes of the Institute.

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Central Govt. officials. Consultancy is permitted without any ceiling on the annual consultancy remuneration. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 110 001 (India). (Fax: 3710618. Telex: 031-65202 CSIR IN, 031-66147 CSIR IN, Gram: CONSEARCH, NEW DELHI).

SERC Winter School on Databases, Numerical Methods and Computer Modelling in Modern Approach to Petrology (NMCMP-III)

A Winter School on the above subject will be held from 2 to 22 January 1996 at the Department of Earth & Planetary Sciences, University of Allahabad, Allahabad. The NMCMP-III will be directed towards teaching/demonstration of laboratory techniques in experimental petrology, and application of mathematical and computer principles in igneous petrology. Broadly, the course content will include: classification, chemical variation, and structural control of igneous rocks; texture of igneous rocks; phase equilibria relations; petrochemistry of the crust, mantle and core, mantle dynamics; magma: its physical and chemical properties; process of magma generation; diversity of igneous rocks – isotopes and REE-modelling and ore genesis in magmatic systems.

The course is open to university/college teachers, research scholars, scientists of research institutions/professional organizations up to 35 years of age. For details of the course and the application form please write to:

Prof. Alok. K. Gupta,
Course Director (NMCMP-III),
Department of Earth & Planetary Sciences,
University of Allahabad,
14, Chathem Lines,
Allahabad 211 002.

The last date for submission of application is 15 November 1995.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Dynamics of the Indian population: Changes in fertility patterns

India has emerged as the largest producer of human beings - more additions per year than any other country in the world (including China). The need to cut down this rate has been felt very strongly for more than half a century, and over Rs 5500 crores have been spent on the family planning programme (as of 1990). Paradoxically (or, to be cynical, expectedly), the annual growth rate of 1.97% seen in 1991 is, if anything, marginally higher than the 1.96% seen during 1951-61! Is the situation really as dismal as it appears to be?

A critical analysis of the numbers behind these numbers, described by K. Srinivasan in his article on **page 577** of this issue, however, reveals some very positive aspects. The net growth rate is the difference between the death rate and the birth rate, and though the difference has remained unchanged, both these rates have substantially decreased. Secondly, the fertility rate - average number of children born per woman - has shown a more pronounced decrease, especially in recent years.

The fertility rate is influenced by a number of social, economic, cultural and demographic factors, and this article examines three of the important ones - infant mortality, female literacy and contraceptive use. Multivariate analysis of statewise data across decades consistently shows the female literacy rate to be the dominant factor. Quantitatively, a 20% increase in female literacy is expected to decrease the fertility rate by one child.

What of the future? The article also attempts to project the fertility rates for the next two decades using several alternative scenarios. The good news is that a (highly desirable) fertility rate of 2.0 is quite likely to be attained. See **page 577** for the rationale behind this optimism.

Fungus that feeds on petrol

Brick-biting, blade-chewing and automobile-consuming people have made news too frequently; we have also heard of those who develop a strong addiction to the odour of petrol and kerosene. But it is rare to hear of organisms that 'drink' petrol for their energy needs. J. Savitha and C. V. Subramanian from the Centre for the Advanced Study in Botany at the University of Madras, report of a strain of fungus that does exactly this (**page 596 - 600**). About ten years ago, this group isolated from the effluents of the Madras Oil Refineries, a strain of *Aspergillusflavus* that degrades the hydrocarbons in crude oil. This organism obviously, is potentially useful in cleaning up the ecosystems that are polluted with the crude oil from the industrial effluents or from the oil sleaks in the ocean.

Such organisms, both fungi and bacteria that live in the soil and aquatic systems enriched with crude are being reported ever since the late sixties. Perhaps one of the most interesting among them is the isolation of two strains of *Cladosporium resinae* from the aircraft jet fuel systems by Cofone and his colleagues at the University of Dayton, Ohio, USA. But some of the earlier reports did not clearly establish whether the fungi isolated from the oil-rich soils and marine ecosystems could indeed use and degrade the crude oil on their own. It was suggested that the fungal mycelia might only help in penetrating the insoluble substance such as oil and in increasing the surface area for bacterial attack.

In the recent past, however, these doubts are swept aside and substantial evidence exists to indicate that the fungi indeed consume and degrade the crude oil from the polluted systems. Savitha's group, besides adding another fungus to this list of oil-eating organisms, has also compared for the first time its enzyme activities when grown on glucose with that when grown on crude petroleum oil. Their study shows that *A. flavus* growing on crude oil exhibits 3 to 6-fold enhanced lipid levels with a significantly altered fatty acid profile. They also show that such enhanced lipids in the tissue are brought about by the altered activity in a set of enzymes that probably facilitate the oxidation of alkanes in the crude oil. But what is the significance of such enhanced lipid levels? Is it merely a physiological consequence of 'living' in the oil or is it a physiological adaptation of overcoming the problems of overconsuming the oil? Clearly, the work by Savitha and her group opens up more interesting questions besides being potentially useful in applied microbiology.

K. N. Ganeshaiah

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

you're sure to benefit by advertising here.

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers—students, doctoral scientists and professionals in virtually every field of scientific activity in India.

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

Write now, or send your copy to

CORRESPONDENCE

Assessment of research impact of engineering institutions

The dictum 'Garbage in: Garbage Out' applies not only to computers but also generally to any creative process. Based on outdated, incomplete and questionable 'scientometric' data of Nagpaul, Prathap (*Curr. Sci.*, 1995, **68**, 869) has drawn some misleading conclusions on assessment of research of major institutions in engineering during 1987–89. Prathap is obviously aware of the fact that 'too little information is a dangerous thing', but all the same he has gone ahead with his analytical exercise.

Let us keep in mind that each engineering institute has its unique features and contributions. We must compare apples with apples and not with oranges. Indian Institute of Science, Bangalore, is primarily a research institute. It has the largest faculty and the largest budget compared to the IITs, and its faculty has little or no teaching. Benaras Hindu University is the largest university in the country with all possible disciplines, including some engineering disciplines. Even the IITs, which have a lot in common (e.g. heavy emphasis on innovative teaching), have many distinctive features. The faculty strength varies from about 300 in IIT Kanpur to over 500 in IIT Delhi. The number of departments/centres varies from about 15 (Kanpur) to 27 (Kharagpur). Even among IITs, a comparison has to be made between comparable departments/centres. And this comparison should include publications, Ph D/M Tech theses, consultancy projects, sponsored projects, industrial interaction, entrepreneural activities, etc. Besides conventional departments/centres, each IIT has some unique departments/centres. For example, Kharagpur has Departments of Mining Engineering, Naval Architecture and Ocean Engineering, Architecture and Planning, and Centres such as Cryogenic Engineering, Rubber Technology, Post-

Harvest Technology, Aquaculture, Biotechnology, Reliability Engineering, etc. Each departments/centre in any IIT has its own R&D culture, which does not necessarily mean publications. Thus, some departments/centres have very few publications but have a very high reputation of their R&D contributions to the industry and other public/private institutions.

Tables 1–3 list comparative statistics of recent publications from the five IITs which are readily available in our Electronic Library and have been obtained from different sources: (1) Current Contents on Disc (CCOD), (2) INSPEC and (3) IEEE/IEE. Each source refers to a group of disciplines, as explained in the captions. Of these groups, the IEEE/IEE publication data are more meaningful for comparison since all IITs have comparable (though not same size) departments in the field. The data in these tables clearly contradict the conclusions of Nagpaul and Prathap and bring out the eminent position of IIT Kharagpur among IITs. The need to do a systematic and in-depth analysis to arrive at 'impact' parameter is clear. Further, such an analysis should take into account other factors such as the number of Ph D's in engineering/technology, number of consultancy and sponsored projects and interactions with industry. Just to give a feeling of the numbers, IIT Kharagpur produces over 100 Ph D's per year, undertakes about 200 projects worth over Rs 1.00 crore as consultancy fee and over Rs 6.00 crore as sponsored R&D projects. Besides, our 30 faculty members have established enterprises, based on their work, in our Technology Park.

Finally, let me emphatically state my faith in critical assessment and accountability of any institution. Indeed, if we do ever hope to see decent standards of R&D in our country, it will be possible only after we have learned to conduct impartial, objective and ruthless peer reviews by nongovernment organizations. Some belated steps taken by UGC and AICTE for accreditation of academic institutions continue to be controversial. It is most unfortunate that our several Academies have failed to appreciate their responsibility to serve the country in this direction. What we need is fiercely independent organizations such as those existing in USA and UK to examine the credentials of each department of an educational institute. We will reach maturity only that day when such an organization will undertake comprehensive analysis to publish publicly 'grades' earned by our academic departments and institutions.

K. L. CHOPRA

Indian Institute of Technology, Kharagpur 721 302, India.

NEWS

Report on the 'International conference on symmetry methods in physics' (ICSMP-95)

The VIIth ICSMP-95, held at the Bogoliubov Laboratory for Theoretical Physics, Joint Institute for Nuclear Research, Dubna, from 10 to 16 July 1995, is the seventh conference in a series, the first five of which were organized by Yu A. Smorodinsky and the sixth was devoted to his memory. This conference was inaugurated by A. N. Sissakian (JINR), and D. V. Shirakov gave some statistical details about the Bogoliubov Laboratory of Theoretical Physics of JINR, where research is carried out in the areas of fields and particles, nuclear theory and theory of condensed matter.

The first (40 min) Invited Talk was by H. D. Doebner (Germany), who spoke on 'Infinite-dimensional symmetries and nonlinear physics'. There were in all 12 Plenary Sessions in which 44 Invited Talks were presented, and 18 Parallel Sessions, in which 85 contributions (of 30 or 20 min duration) were presented. From India, there were three invited speakers (the two authors of this report and M. Lakshmanan of the Bharathidasan University, Tiruchi).

Broadly, the topics covered included the following: dynamical symmetries and integrable models; symmetry and nonlinear phenomena; special functions and group representation theory; quantum algebras and groups; supersymmetry (SUSY) from quantum mechanics to elementary particles; gauge and conformal theories; symmetries in condensed-matter physics and statistical mechanics; geometric methods in quantum mechanics and quantum field theory; quantum optics and coherent states; and mathematical methods.

In a review of the renormalization group (RG) method introduced 40 years ago by Peterman and Stuckelberg, Gell Mann and Low, and N. N. Bogoliubov, D. V. Shirakov (JINR) pointed out that this work led K. Wilson to apply RG method to critical phenomena in the 1970s and that recent analysis identifies the RG with functional self-similarity. In his invited talk 'RG, solution symmetry and Lie group analysis', Shirakov said that Wigner's 1963 Nobel lecture traced the laws of Nature as derived from symmetry and invariance principles and these laws, in turn, explained physical phenomena. The Bogoliubov RG method adds to this scheme Lagrangian parameters and boundary parameters as inputs to the laws of Nature and the physical phenomenon respectively.

P. Winternitz (Canada) in his invited talk on 'Continuous and discrete symmetries of differential-difference equations' showed how the established Lie group analysis of ordinary differential equations (ODE) has been extended to the study of differential–difference equations. The three different approaches to the Lie point symmetries of discrete equations are beginning to converge and similar analysis of q-difference equations

are being made; algorithms, techniques and computerization of these approaches are emerging. M. Lakshmanan (India) in his invited talk on 'Lie symmetries of certain $(2+1)$-dimensional soliton systems' showed how the methodology of similarity reductions applied earlier to $(1+1)$-dimensional problems has been extended to several $(2+1)$-dimensional systems and that all the five cases considered have ∞-dimensional Lie algebras but not all are of the Virasoro type. One of us (A.K.) in an invited talk on 'Singular solutions of KdV and MKdV equations' discussed the construction and properties of the positon and negaton solutions. Just like soliton solutions, these solutions also do not change their shape after scattering and in some cases there is not even a phase change. That the positon solutions are intimately related to 'bound states in continuum' was discovered in 1929 by von Neumann and Wigner. T. A. Weber (USA) in his contribution on 'An extended Gel'fand–Levitan method' presented a study of the resonances of perturbed von Neumann–Wigner potentials.

A. J. Macfarlane's (UK) contribution was on 'Odd-dimensional fermionic phase space and SUSY'. He discussed the algebra of Dirac and Majorana fermions, and showed that fermionic SUSY on a manifold can be constructed. He discussed the case of SUSY with one real supercharge and the problem of a nonrelativistic particle with spin $-1/2$ in a monopole field. S. Duran (Canada) discussed the generalization to 'Fractional SUSY and quantum mechanics', wherein the Hamiltonian is expressed as $H = Q^F$ $(F = 2, 3, \ldots)$, where Q is the supercharge. G. Junker (Germany) discussed Witten's model of SUSY quantum mechanics in his contribution on 'SUSY and its quasiclassical approximation'. The lowest-order quasiclassical approximation is exact for shape-invariant potentials, and for others the resulting approximate spectra are sometimes better than the WKB approximation. M. Zonjil (Czechoslovakia) presented 'Two numerical aspects of SUSY in quantum mechanics', establishing the numerical efficiency of using the Pade approximated superpotentials and the consequences of employing the superpotentials in certain nonvariational treatments like the Hill determinant method. J. Casahorran (Spain) in his contribution on 'Obtaining solvable potentials in the framework of SUSY quantum mechanics' discussed the consequences of SUSY in the context of singular potentials. B. N. Zakhariev (JINR) discussed 'New situation in quantum mechanics (inverse problem and SUSY approach)', wherein he pointed out analytic methods to obtain new potentials whose spectrum and S-matrix are identical to a given potential except for the bound-state energy of one state. L. M. Tomilchik (Belarus) in his contribution on 'SUSY Dirac oscillator: Quantum and classical aspects' discussed the connection between the properties of the Dirac and the classical oscillator in the nonrelativistic and ultrarelativistic limits. A. M. Shirakov (Russia) discussed in his contribution on 'Accidental degeneracy' a situation when there is a degeneracy of levels in the quantum system that does not seem to correspond to any symmetry of the Hamiltonian. As an illustration he offered examples from the spectra of nonrigid spherical molecules.

V. S. Varadarajan (USA) pointed out in his invited talk on 'Quantum semiclassical groups' that corresponding to each method of describing a Lie group a type of deformation is associated and that the Drinfeld–Jimbo deformations are topological algebras. He focused his attention on arithmetic deformations in which real numbers are replaced by p-adic numbers, the real field is replaced by the p-adic field and Hilbert spaces are over p-adic fields. In this scheme, conventional quantum mechanics is obtained as a limit of finite quantum mechanics. In his q-quantum mechanics, p-adic oscillators and p-adic Coulomb problems arise. The hope in q-quantum mechanics is that the divergences of quantum electrodynamics and field theory will be ameliorated. However, deformation of space–time leads to violation of causality, which is troublesome. M. Arik (Turkey) in his contribution on 'Quadratic q-oscillators' gave a formalism which gives as special cases all the well-known quadratic oscillators and, in particular, he constructed homographic, squeezed, square root and chaotic q-oscillators.

G. Rosensteel (USA) in his invited talk on 'Galactic dynamics in the Siegel-half-plane' models the dynamics of rotating galaxies by a Hamiltonian Lax system for which the phase space is a G-manifold with the Lie group G being either the noncompact $\mathrm{Sp}(n, \mathrm{R})$ or a maximal parabolic group $\mathrm{GCM}(n)$. He showed that the dimensions $n = 1, 2, 3$ correspond, respectively, to breathing mode oscillations, planar rotations, and three-dimensional collective motion, and that the homogeneous GCM(3)-manifolds correspond to the Riemann ellipsoids. This work provides a group-theoretic setting for Chandrasekhar's lucid exposition on *Ellipsoidal Figures of Equilibrium* (Yale University Press, 1969). The homogeneous G-manifold $\mathrm{Sp}(n, \mathrm{R})/\mathrm{U}(n)$, where $\mathrm{U}(n)$ is the maximal compact subgroup, was shown to be a classical complex domain diffeomorphic to the Siegal upper half-plane S_n. Equilibrium galactic radii were determined for S_1 systems.

J. P. Draayer (USA) in his contribution on 'Modern applications of SU(3) symmetry and its sp(3, R) extension in nuclear structure physics' pointed out that the SU(3)/sp(6, R) applications started in 1960 for light nuclei $(A < 40)$, extended to the transition region $(40 < A < 100)$ in the 1970s and after a lull in the 1980s picked up interest recently after the success of SU(3) applications to heavy nuclei $(A > 100)$. He discussed some interesting recent work where the origin of pseudospin symmetry in heavy nuclei has been related to chiral symmetry in nuclei. Superdeformed bands have been observed in the $\mathrm{sp}(6, \mathrm{R}) \rightarrow \mathrm{SU}(3) \rightarrow \mathrm{SO_L}(3)$. The pseudo SU(3) scheme has been applied to the study of double β decay of nuclei. D. Benatsos (Greece) in his contribution on 'Quantum algebraic symmetries in nuclei and molecules' discussed super- and hyper-deformations in nuclei and atomic clusters in terms of anisotropic harmonic oscillators with rational ratios of frequencies. I. Pavlichenkov (Russia) in his contribution on 'Symmetrical bifurcation in quantum rotational spectra' considered bifurcation in rotational spectra as a fundamental phenomenon existing in different systems involving different energy scales. Odd nuclei ^{171}Yb and ^{169}Yb show bifurcation, and Coriolis forces tend to align the bands.

K. B. Wolf (Mexico) in his contribution on 'Conformal optical systems' pointed out that the most natural realization of conformal SO(4, 2) symmetry is found in optics. The Maxwell's fish-eye, i.e. the optical system of a transparent medium with spherically symmetric refractive index, had the SO(4, 2) Lie algebra of Poisson brackets. The 'hyperbolic' fish-eye has also been shown to be an optical system possessing conformal SO(4, 2)

symmetry. He pointed out the analogy of the spherical fish-eye to the hydrogen atom problem. A. I. Solomon (UK) discussed the many variations of the successful exact mathematical model of Jaynes–Cummings, which treats a two-level atomic system. In his contribution on 'Jaynes–Cummings variants', he detailed supersymmetric versions of the model and generalizations to the multilevel atomic and multiphoton systems. R. Mc Dermott (UK) in his contribution on 'Coherent and squeezed states parametrized by noncommutative variables' detailed the group-theoretic and Robertson–Schrödinger uncertainty relation approaches to coherent and squeezed states, discussed the properties of the unitary q-displacement Heisenberg–Weyl operator and that of the squeezed vacuum state and its q-generalization. V. L. Derbov (Russia) in his contribution on 'Geometric phases of the generalized polarization of coherent states in quantum optics' showed that the geometric phase provides valuable additional information on the polarization structure of quantum light related to the appropriate dynamical symmetry and suggested experimental measurement of the components of the polarization vector.

One of us (K.S.R.) in an invited talk gave a survey of the 'Quantum theory of angular momentum and generalized (ordinary and basic) hypergeometric functions'. It was shown that sets of hypergeometric functions are necessary and sufficient to account for the symmetries of the $3-j$ and the $6-j$ coefficients, that different ${}_3F_2(1)$ forms for the $3-j$ coefficient known in the literature are derivable from the Van der Waerden form using the transformation theory of hypergeometric functions, that the $9-j$ coefficient's triple sum series due to Alisauskas–Jucys–Bandzaitis can be identified with a triple hypergeometric series, that the $3-j$ and $6-j$ coefficients are related to the Hahn and Racah polynomials, respectively, and that most of these results have been q-generalized. A. Ronveaux (Belgium) in his survey talk on 'Orthogonal polynomials: Recurrence relations for connection and linearization coefficients' presented a simple approach to build recursively the connection coefficients between two families of polynomials and applied it to the classical discrete families (Charlier, Meixner, Krawtchouck, Hahn). M. Noumi (Japan) in his invited talk on 'Reflection equations, quantum-homogeneous space and q-orthogonal polynomials' classified the classical compact symmetry space into ten series and, by the method of reflection equations, he constructed a q-nonsymmetric space (G/K) and, for each (G/K), in seven of ten cases, the resulting zonal spherical functions were expressed in terms of Macdonald polynomials or multivariable Askey–Wilson polynomials of Koornwinder. E. G. Kalnins' (New Zealand) contribution on 'Separation of variables (special functions and modern developments)' detailed how this classical theory is closely related to that of integrable systems and showed how one can systematically classify certain classical mechanical systems via separation-of-variables techniques. R. M. Asherova (Russia) in her contribution on '$U_q(3)$ Weyl coefficients and $SU_q(2)$ Racah coefficients' used the projection operator approach to derive a general analytic formula for transformation brackets between U- and T-bases of $U_q(3)$ irreps. (so-called Weyl coefficients). A resummation technique of q-factorial expressions was used to prove that the Weyl coefficient coincides with the q-Racah coefficient for $su_q(2)$. L. A. Shelepin (Russia) in his contribution on 'Clebsch–Gordan coefficients in coherent and mixed basis' considered a generalized theory of angular momentum including both discrete and continuous parameters and introduced mixed Clebcsh–Gordan coefficients which relate the basis of common $|jm\rangle$ states and coherent states.

The above report presents some of the highlights of the Conference which was well organized and conducted by G. Pogosyan and his dedicated group at JINR. A welcome party, a boat excursion on the picturesque Volga river culminating in a barbecue dinner on an island in Moscow sea, a concert by a Dubna children's choir and a trip to Sergiev Posad, the Russian orthodox centre with its 500-year-old trinity monastery provided adequate relaxation during the week-long deliberations.

The conference concluded with its dedication, by Jelepov of JINR, to the memory of Yu A. Smorodinsky, who along with Pomeranchuk and Migdal was one of the outstanding active theoreticians invited to lecture at JINR soon after it was founded. He recalled with gratitude Smorodinsky's warm personality, broad interests, pioneering work on isospin theory, his new approach to high-energy nucleon–nucleon scattering with a potential including exchange forces, his book *Lectures on Theory of Atomic Nuclei*, with Landau which was translated into French and English (by Dover), and above all the importance he gave to symmetry concepts in physics, which played a big role in the development of this area. It is hoped that this series of conferences would become a permanent feature of JINR, Dubna.

The altered state of the former Soviet Union seems to have one depressing consequence in that, during the past five years, competent people are leaving the country and fewer students have enrolled for higher studies in theoretical physics and pure and applied mathematics – these of the areas in which the people belonging to the former Soviet Union have made deep and profound contributions. We sincerely hope that this is also but a temporary phase in these new nations, which are trying to become economically strong and highly competitive in this materialistic world of ours.

Traditional ecological knowledge and sustainable use of natural resources

A recent publication of the UNESCO discusses 'TEK' – traditional ecological knowledge and its functioning in tropical countries[1]. It identifies three broad categories of TEK, viz.

1) knowledge about specific components/aspects of environment: plants, animals, soils and environmental phenomena which are comparable to systematics,

2) development, evolution and use of appropriate technologies for farming, forestry, hunting, fishing and trapping, and

3) understanding of and intimate relationship with environmental systems as a whole; the most complex and least understood.

TEK has gained much more attention and importance in the field of conservation of biodiversity recently than during the past. Worldwide, a number of government and nongovernment institutions are studying the various dimensions of this natural product both generally and specifically, attempting to build it into the numerous conservation strategies that are being suggested every day. For example, a lot of debate on biodiversity, trade and IPR (Intellectual Property Rights) related issues have stemmed from the overall awareness of TEK; the various round tables on assessment, conservation and sustainable use of genetic resources (prior to the Bahamas Conference of Parties organised by the Stockholm Environment Institute in Latin America, Africa and Asia) and more recently the Seville Strategy of the UNESCO's Man and Biosphere (MAB) programme that was held in Spain (20–25 March 1995). TEK is believed to have been recorded in a variety of ways. They include symbols, phonetics, narratives, rituals, music and dance. Subsistence technology (involving a wide range of natural products), fertility control, settlement patterns, social structure with specific values and norms, acceptance and practice of sorcery, reliance on shamanic powers, forest spirits and supernaturally protected areas (sacred groves) are all considered as tell-tale signs of prevailing TEK in human communities[2].

In the midst of all the emphasis laid on TEK and how best science can acknowledge it, there has always emerged the question 'What do we really know about TEK?' and the statement 'there is a greater need to have information and clearcut examples and case studies'. The best thing at this time would, therefore, be to analyse the Indian TEK that we are familiar with in the context of the conservation and sustainable use of biodiversity and natural resources including air, soil and water.

In India, TEK of medicinal plants and conservation of crop genetic resources in the form of seed banks and locally grown land races have attracted the attention of conservation biologists. Some of these knowledge systems and practices are being systematically documented, especially in the light of developing rewarding systems to the indigenous people who possess them.

Traditional knowledge of macroorganisms in local humans is a fact. For instance, analysis of local names collected of birds in the Uttara Kannada district in the state of Karnataka between 1983 and 1988 suggest that the humans traditionally practised some nomenclatural system as that of modern taxonomy. 169 specific Kannada and Konkani names of birds used by local humans in the district clearly refer to 84 species; a few common and game birds having as many as 7 names. Of these, 38% have a generic identity referring to birds in the same taxonomic family. Another 12% was based on superficial resemblance to unrelated birds, which are rather similar to referring to the coucal as 'crow pheasant' or the chloropsis as 'green bulbul' in English.

Whereas TEK of the various components of the ecosystem and an intimate association with them have been quite convincingly recorded, 'appropriate technologies' for farming, harvesting, etc., that we frequently search for amongst the indigenous people are as yet not fully authenticated although there is little doubt that TEK does include appropriate technologies for harvest of natural resources.

Personal experience suggests that the supportive evidences quoted relating TEK and sustainability of natural resource use by traditional humans are anecdotal and equivocal. For example, some forest dwellers of the Annamalai Hills in south India called *Malasars* are subsisting largely as hunter–gatherers even today. Ethnobotanists who have visited and studied TEK in the use of local plant resources have highlighted the prudent behaviour of these humans with regards harvesting. Tubers of wild plants such as *Dioscorea* are collected only when the plants show signs of maturity. After removing a substantial portion of the tubers, the remaining parts along with the vines are planted back carefully to allow for regeneration. In case where the available tubers are very large, they are shared amongst more members of the community and so on. However, watching the same *Malasars* catching fish in a small river does not provide any evidence of being prudent.

A few men and women together block the flow of the water to start with. An old *saree* is dragged by a pair of *Malasars* along the bottom of the pool and everything that cannot possibly pass through the saree or jump over it is collected, brought to the shore and emptied on the sand. The choice fish are picked up and put inside a small pit dug beside the pool, while the rest including tadpoles and smaller species of fish are just allowed to perish on the shore. Further, the pool remains as such till probably the next rains. Such fishing methods are also practised elsewhere in the tropics of Asia, viz. Northern Thailand[3].

Traditional fishermen catch fish with nets, bamboo traps, pots and even bare hands in many parts of south India. Incidental killing of nontarget organisms is considerable in all these methods. (In our opinion, it is only a magnified form of this practice that we see in modern mechanized fishing wherein 27% of the global harvest is of nontarget species.)

Other examples may be quoted of *Irulas*, hunter–gatherers around Madras. These people randomly set up pit-fall traps and nets in large areas which collect a wide variety of small vertebrate animals. *Irulas* pick up only the choice prey leaving the others in the pits to die. As per the optimal foraging theory, any organism would try to maximize the benefits

derived from the harvested food by way of reducing the energy spent on searching and handling it. A selective mode of harvest of mobile organisms in large areas as that of fish in extensive water involves a greater expenditure of energy than collective harvest and discarding the unwanted. Hence, it is justifiable that humans will naturally resort to the second method of harvest although it involves considerable wastage. In this regard, both traditional and modern approach, as one would expect, would not vary considerably.

Having mentioned a couple of negative examples regarding sustainable harvest of natural resources we may now consider a few positive cases. In south India, the month of July (the onset of southwest monsoon) traditionally used to be a closed season with little harvest of sea fish. Incidentally, this is also the season when most of the choice fish such as seer and pomphrets breed. They come closer to the shore for spawning. Mechanized boats which are being used currently all through the year in all our coastal waters are netting large females and males ready to spawn, considerably reducing the potential for future generations. Although the sea is usually rough during this season, discouraging the use of traditional rafts and boats, one may very well interpret the closed season that used to be observed in the past as a prudent TEK in favour of sustainable harvest of fish.

Instances of local humans using plant poisons to temporarily paralyse fish in pools of freshwater, collecting the select individuals and allowing the rest to 'recover' from the shock are in favour of TEK of sustainable harvest. This is a common practice over most of the south Indian hills. (No effort has, however, been made to record the incidental killings in this method.)

Thus, one can argue back and forth quoting examples which either support or contradict the 'TEK of sustainability' hypotheses. If there are positive examples, there certainly exists an equal number of opposing evidences in this context. Yet the purpose of this article is not to make the readers feel that there is no truth in TEK when it comes to sustainable use of natural resources. This system which has been tried and practised over a few thousand years cannot be ignored altogether. What is needed, however, is an emphasis on more carefully collected and analysed data which is scientifically scrutinized and interpreted. Kenneth Ruddle, writing for UNESCO, says 'study of tribal knowledge in my opinion is not going to tell us more about sustainable harvest but help us understand that they are ecofriendly and can be allowed to exist even within protected areas'. Quoting Ruddle further while closing this brief article on TEK, it is appropriate to state the following. 'The romantic and uncritical espousal of traditional ecological knowledge and management is as extreme and almost as unfortunate as that of dismissing it. Traditional peoples have not lived in some preternatural state of harmony with nature. Some of their abuses of natural resources have been and remain substantial'[4].

Endophytes – A crucial issue

Microorganisms are known to interact with plant surfaces as well as interior tissues. Microbes which live with interior tissues of healthy plants without causing disease symptoms are called 'endophytes', the term synonym of 'mutualists'. Although this concept was confined initially to fungi, later it was expanded to include all microbes which colonize internal plant tissues without causing harm to their hosts[1,2]. In the last decade, major attention was focused on studying the plant interactions with rhizobia and vesicular–arbuscular mycorrhizae (VAM). A few years ago it was understood that a wide range of plants was infected with endophytic fungi. Endophytic fungi have been reported from different plants such as mosses and ferns[3], conifers[4,5], palms[6], and monocots[7]. To date, the ecological role of endophytic fungi is poorly understood. The purpose of this note is to emphasize the gaining importance of endophytes other than rhizobia and VAM.

Endophytes occupy a unique ecological niche and have major influences on plant distribution, ecology, physiology and biochemistry. The studies on the endophytes of grasses, conifers and other woody perennials indicated several beneficial effects. Endophytic infection enhances the resistance of host plants against insects[8]. It was hypothesized that endophytes of conifers and woody perennials decrease palatability for grazing insects and antagonize pathogens[5,9,10]. Thus, to improve their fitness in a given environment, plants might have acquired/accommodated the endophytes.

Endophytes so far isolated were either ascomycetes or their anamorphs and zygomycetes, whereas those belonging to basidiomycetes or their anamorphs or other fungi were rarely reported[3,11]. Several fungi adapted endophytic lifestyle possibly because of the competition of different fungi on suitable substrates. Endophytes are in an advantageous position to colonize the plant parts starting from the initiation of senescence. Endophytes usually bear fruit after the host has died, hence, senescent or dead twigs might be excellent materials to establish anamorph–teleomorph connections.

There is a notion that endophytes have evolved from plant pathogenic fungi. Endophytes may often cause pathological symptoms when the host is under stress[12,13]. These may also behave as latent pathogens, under situations which disrupt the endophyte–plant association (for instance, modern agricultural practices), where endophyte-intolerant host selection will be favoured and transition of endophyte to pathogen might take place[9]. Endophytic, pathogenic and saprophytic behaviour of fungi might be host/environment-dependent. To derive maximum benefits from fungi, plants have to cope with the changing environment to maintain fungi in endophytic rather than pathogenic state, but during senescence of plant parts naturally endophytes switch over to saprophytic phase. Several readjustments have to be made to decide the nature of microorganisms as and when we explore more about endophyte–plant interactions. Some endophytes might behave as pathogens under specific environmental conditions. The decisions taken on microorganisms as plant pathogens or seed pathogens have to be reconsidered with caution. The bacterial or fungal appearance on surface-sterilized excised plant parts in tissue culture can be strongly suspected as endophytes. Plant–endophyte association is an excellent model system which facilitates to understand evolution of plant–microbe symbioses.

Endophytes are known to infect different plant parts either by vertical transmission via host seeds/vegetative propagules or by horizontal transmission. It is now known that climatic conditions greatly influence fungal spore germination and ultimate infection. The increase in rainfall increases the level of endophytic infection. The deposition of surface runoff along the midrib/lamina of leaves favour fungal spores to collect and subsequently to infect heavily[14]. It is also known that aquatic roots of riparian vegetation are colonized by aquatic hyphomycetes, and it is suspected that the selection pressure might have been induced by scarcity of substrates[15,16].

Many plant secondary metabolites have structural and qualitative similarities with endophytic allelochemicals and fungal toxins[17]. The possibility of endophytes acting as vehicles of horizontal gene transfer between the genomes of fungi and plants cannot be ruled out, if the endophytes are not the allelochemical producer. Interestingly, many grass endophytic fungi are known to produce alkaloids which act as insect repellents. Several grasses which possess endophytes (infected by *Acremonium* spp.) are toxic to livestock. Surprisingly, on grazing some grasses cattle, horse and sheep get intoxicated and that is why animals avoid grazing such stuff[8]. It is now known that the intoxicating effect is due to the metabolites of endophytic fungi[18]. The properties of plant parts in curing human/animal ailments and as intoxicants and toxins might also be influenced by the endophytic partner. Endophytic fungi are now recognized as a potential source of new secondary metabolites[19]. Endophytes are known to produce compounds active against human and plant pathogenic bacteria[20–23]. Besides these, endophytes including VAM produce hormones such as indole-3-acetic acid (IAA) and cytokinins which stimulate growth and flowering of plants[24,25]. Endophytic niche is considered as the potential source of microbes which produce a wide variety of bioactive metabolites. It has become a new source of biochemicals like those from soil, freshwater and marine ecosystems.

Dreyfuss and Chapela[26] estimated that over 1.3 million endophytes are awaiting discovery. The study of endophyte distribution, biodiversity and their biochemical characteristics are of immense importance in plant biology to understand and to improve plant fitness; to develop safe biocontrol chemicals; to produce environment-friendly chemicals in industrial scale. The distribution and fitness of plants in a given environment; physiological performance of plants and biochemical features of plant tissues have been greatly influenced by endophytes. There are many benefits to be derived and several questions yet to be answered regarding endophyte–plant interactions.

Accelerators – Achievements and future projections*

R. Chidambaram and S. Kailas

Charged particle accelerators are being used not only for basic research but also for various applications. Accelerator activity started in India almost four decades back and we have now the capability and expertise to design, build and operate many types of accelerators which are required. International collaboration has been pursued in programmes involving large accelerators. In the present article, a brief description of the Indian Accelerator Programme, its achievements and future projections, is given.

CHARGED-particle accelerators are being increasingly used, both directly and indirectly, for research in many frontier areas of science. They are also indispensable for varied applications ranging from materials science to medicine and, more recently, even for radioactive-waste transmutation.

As India has achieved, over the years, the distinction of being able to design, build and operate many types of accelerators which are required, it is timely to take stock of the Indian Accelerator Programme. Just as the design and construction of a reactor involves competence in several areas and integration of several subsystems, so does the design and construction of an advanced accelerator, and the units of the Department of Atomic Energy (DAE) are uniquely equipped to undertake this task. Further, with increasing interest in indigenous accelerators, both for research and for applications, and possibilities of increased participation in international projects, both in construction and for research, it is useful to review our achievements and attempt to define future possibilities in this area. It is inevitable that this paper emphasizes the work done in the DAE – considering the affiliation of the authors – but we have tried to include, to the best of our knowledge, the contributions to this field from the university system.

Historical development up to the eighties

The work related to various types of accelerators began in India in the forties and the fifties, though in a modest way. In the sixties India had a reasonably large size accelerator in the form of the 5.5 MV Van de Graaff accelerator at the Bhabha Atomic Research Centre (BARC), purchased from High Voltage Engineering Corporation, USA. The accelerator-building activity took a quantum jump with the indigenous development and commissioning of an 88 in. variable energy cyclotron at Calcutta (VECC) in the seventies (see Box 1). Around the same time a 2 MV tandem Van de Graaff accelerator was made operational fully through indigenous efforts at Trombay. In the eighties, to catch up with the ongoing research in the important area of heavy ions, we embarked on a medium-energy heavy-ion facility in Bombay (see Box 2). Though the 14 MV pelletron, the first of its kind in India, was imported from National Electrostatics Corporation (NEC), USA, several subsystems such as the 25 m high, 5.5 m wide accelerator tank to contain the SF_6 gas at high pressures, the four storage tanks for SF_6 gas, the beam lines and the experimental facilities were all fabricated and set up indigenously. This joint BARC–TIFR facility located at the Tata Institute of Fundamental Research (TIFR) campus has now been operating for more than five years and in this period with the use of this facility considerable research work has been carried out in the field of heavy-ion nuclear reactions and in interdisciplinary areas.

Growth in the nineties

In the year 1990, the second pelletron, a 16 MV NEC machine was made operational in Delhi at the Nuclear Science Centre (NSC) of the University Grants Commission (see Box 3). To augment the scope of accelerators for areas other than nuclear physics, a 3 MV NEC pelletron was commissioned in the Institute of Physics, Bhubaneswar, in 1991. Work has already started in converting the 5.5 MV Van de Graaff accelerator at BARC into a folded 7 MV tandem accelerator. The Centre for Advanced Technology (CAT) at Indore (see Box 4) was started a few years back for development of technologies associated with accelerators, lasers and related systems. The first Indian synchrotron radiation source, based on a 450 MeV electron storage ring, Indus-1 (see Figure B4), is already at an advanced stage of construction at CAT. This facility when completed will consist of a 20 MV microtron, followed by a 700 MeV synchrotron and the storage ring. This storage ring will

*Based on the XV Prof. Balakrishnan Memorial lecture of the Indian Vacuum Society given on 14 October 1994 at Bombay by Dr R. Chidambaram.

R. Chidambarm and S. Kailas are in Bhabha Atomic Research Centre, Bombay 400 085, India.

provide soft X-ray and vacuum ultraviolet radiation over a wide spectrum. In the next phase, a 2 GeV storage ring Indus-2 (see Figure B4) to deliver harder X-rays through dipole magnets and wigglers will be built.

Other developments related to the accelerators described above include the work started for the building of superconducting LINAC boosters to enhance the heavy-ion energies from the present pelletrons. At VECC, a versatile electron cyclotron resonance (ECR) ion source has been built and will soon be used as an injector to the present cyclotron to deliver high-energy heavy-ions for experiments from this facility. Plans are also under way to build a superconducting cyclotron at Calcutta. At BARC, work is going on in completing an REQ accelerator which, in principle, can also serve as an injector for a bigger accelerator. There are also plans to build low-energy electron accelerators primarily for medical and industrial applications both in CAT and in BARC. CAT is also building a 20 MeV proton Linac which will consist of a 750 keV RFQ operating at 202 MHz and a drift tube Linac also operating at 202 MHz.

Box 1. Variable Energy Cyclotron Centre, Calcutta

The cyclotron at Calcutta became operational in the late seventies and has been delivering beams of alpha particles for not only nuclear physics investigations but also for other areas of science. Recently, both protons and deuterons of different energies have become available to the user community. Beams of high resolution (about 70 keV) are available for research. In the near future it is expected to reach a value of 10–15 keV. When the ECR ion source is coupled to the present machine, a large variety of medium- to high-energy heavy-ions will be available from VECC. A recently completed experiment utilizing 15–20 MeV/A alpha particles interacting with aluminium has given interesting answers to the production mechanism of fragments heavier than the projectile. From systematic studies of break-up of ^{6}Li using alpha particles from VECC, important results of relevance to astrophysics have been obtained (Figure B1). Another area of research is the study of properties of nuclei far from the line of beta stability, an emerging area of great potential. For this purpose, an isotope separator on-line (ISOL) facility has been developed.

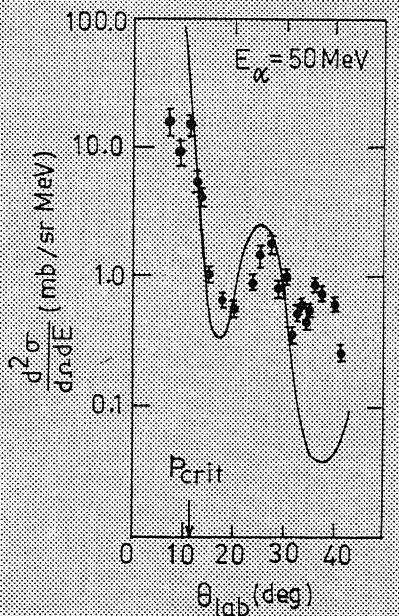

Figure B1. Alpha particle-induced, $^6Li \rightarrow \alpha + d$, target breakup reaction at VECC, Calcutta. The finding of a critical momentum transfer – p_{crit} = 117 MeV/C – which signifies the dominance of the Coulomb breakup, is important in the context of nuclear astrophysics.

Box 2. Pelletron in Bombay

The commissioning of the medium-energy heavy-ion accelerator facility, 14 MV pelletron, in Bombay six years ago has enabled the nuclear physicists in this country for the first time to explore the nucleus in many previously inaccessible regions of excitation, spins and configurations. In order to carry out research in several possible frontier areas, a number of facilities have been set up which include: (a) A general-purpose 1 m diameter scattering chamber of capacity 500 l, (b) Large-area position-sensitive ionization chamber, (c) Array of NaI, BGO, Phoswich and HpGe detectors, (d) Fast electronics and PC/transputer-based data acquisition systems.

Amongst the many interesting results which have come out of this facility, the notable ones are establishing the fission time scales through the use of 'neutron clock' and the experimental verification of the preequilibrium fission mechanism by the BARC group from a series of fission fragment angular distribution measurements (Figure B2). From recent investigations related to quasimolecular resonances in light compound nuclei, it has been possible to establish superdeformed structures in shapes of nuclei with major to minor axis ratio between 2 and 3.

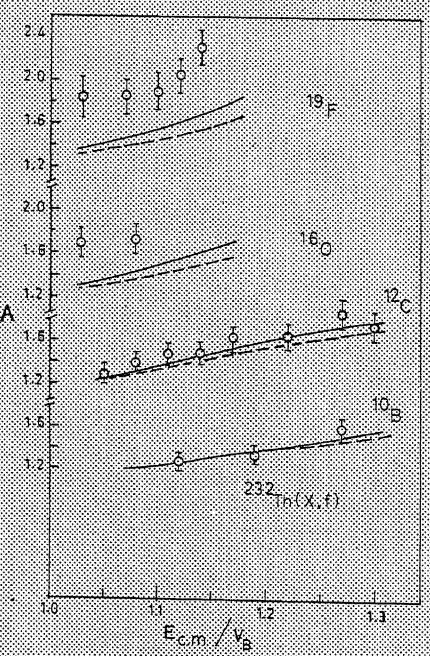

Figure B2. Fission-fragment anisotropies for ^{10}B, ^{12}C, ^{16}O and ^{19}F + ^{232}Th systems measured using the Bombay pelletron. While the systems ^{10}B and ^{12}C + ^{232}Th exhibit 'normal' anisotropies, the ^{16}O and ^{19}F + ^{232}Th systems exhibit 'anomalous' anisotropies. This observation is consistent with the expectations of pre-equilibrium fission model proposed by the Trombay group earlier.

Box 3. Pelletron in Delhi

A heavy-ion facility with a 16 MV terminal has been operational at NSC, Delhi, for the last few years. The NSC user family has members from more than 30 universities, 3 IITs, IISc, besides national labs like NPL, BARC, VECC, IOP, SINP and TIFR. Some of the major experimental facilities which are available in this centre are: (1) The heavy-ion recoil analyser (HIRA) for detection of slow-moving heavy recoils, with a mass resolution of better than 1/200. (2) Gamma detector array consisting of a set of HpGe detectors with anti-Compton shields for high-spin spectroscopy. Additional array of BGO detectors is provided for total energy measurement and it also serves as a multiplicity filter. (3) 1.5 m diameter scattering chamber. Using these facilities a number of experiments have been performed related to subbarrier fusion phenomena and high-spin spectroscopy (Figure B3).

To augment the energies available from these facilities, both at Bombay and Delhi, LINAC boosters based on superconducting technologies are being built. While the one at Bombay will be based on Pb, the one at NSC will be Nb-based. The NSC is collaborating with Argonne National Lab, USA, on this LINAC project.

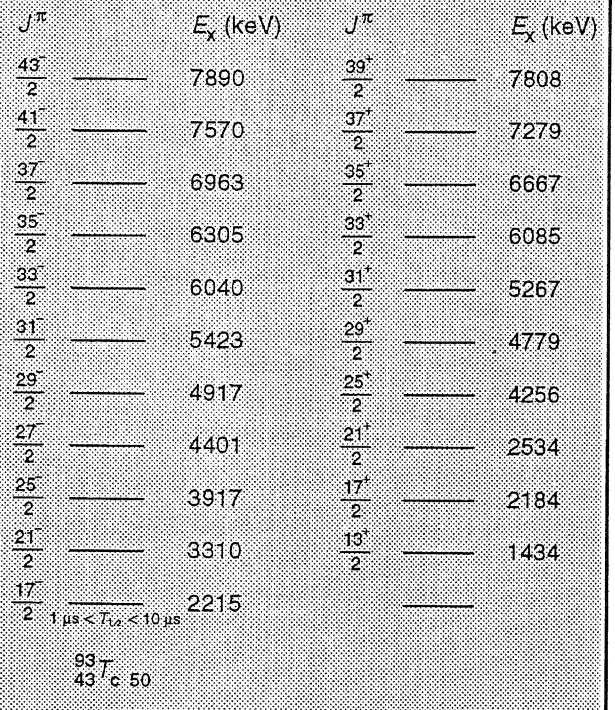

Figure B3. High spin states in ^{93}Tc. Level scheme for ^{93}Tc showing excitation energies and spins (parities), populated through ^{66}Zn (^{31}P, 2p2n) ^{93}Tc reaction at the Delhi pelletron accelerator facility.

A Centre for Compositional Characterization of Materials (CCCM) is being set up by BARC at Hyderabad and some of the analytical techniques used there will employ a 3 MV tandem accelerator. All these go to show that we have in this country several strong groups in the accelerator field and also the necessary infrastructure to design and build indigenously new generations of accelerators and related experimental facilities.

The various accelerator facilities in the country are collectively presented in what can be called the accelerator map of India (Figure 1).

International collaboration

It is very clear that no single country in the world can now afford to build and operate major accelerator facilities and related detector set-ups. International collaborations have become necessary. Our country has been collaborating with major international accelerator facilities in Europe and USA. Our contributions are both in the area of accelerator building and in the development of large-size detectors. The CAT is collaborating with CERN, Europe, both in LEP (large electron–positron collider) and PS (proton synchrotron)/SPS (super proton synchrotron) accelerator upgrades. Titanium sublimation pump bodies have been exported to CERN. It has also supplied other vacuum components and corrector magnets in substantial numbers. A group from BARC and VECC has developed the control software for accelerating Pb ions at SPS facility.

The high-energy physics group from TIFR has been actively collaborating with CERN for a number of years. For the L3 experiment, the TIFR group has supplied 1100 brass proportional chambers, SS housings, precision machined Cu–Te pieces and also a few thousand PCBs. The TIFR group has also contributed to the software and physics aspects of this joint programme, in particular the precision tests of the standard model of particle physics and a search for one of its cornerstones: the Higgs particle. Three major achievements of this experiment are: (1) the number of neutrino species has been established to be three; (2) precision measurement of the electroweak mixing angle; and (3) estimate of the top quark mass.

With the recent availability of relativistic heavy ions from CERN at SPS, the group from VECC has been collaborating with CERN on experiments related to the experimental search for the quark gluon plasma (QGP). The VECC group has built a photon multiplicity detector consisting of 55,000 pads of small plastic scintillators (20 mm × 20 mm) for efficiently detecting the photons as signals of QGP. The optical fibres are inserted diagonally in each pad to pick up the light signal. One successful run has already been completed with a sulphur beam of 200 GeV/nucleon energy using the CERN SPS. Recent analysis of the photon data has perhaps given the first hint of the QGP, entirely from the photon spectrum. Besides VECC, several scientists and students from Institute of Physics, Bhubaneswar, and Indian universities – Chandigarh, Jammu and Jaipur – are also collaborating in this international venture.

Recently, BARC has also entered into collaboration with USA on using the Brookhaven National Lab (BNL) relativistic heavy-ion collider facility (RHIC) in the Photon Electron New Ion Experiment (PHENIX) to

Box 4. Centre for Advanced Technology, Indore

A major centre for advanced technologies (CAT) – accelerator and laser related – has been set up at Indore by the DAE. Work on the first major accelerator facility consisting of a microtron, synchrotron and storage ring for production of high-energy electrons and associated synchrotron radiation is progressing very well at Indore. Major indigenous effort has gone into building this facility from design to fabrication (Figure B4). Sputter ion pumps of speeds 30, 70, 140 and 270 l/s have been developed at CAT for the accelerator and subsystems to achieve vacuum of the order of 10^{-10} mbar. All-metal Pirani and Penning gauges have also been developed to measure pressures from atmosphere to 10^{-9} mbar. Two vacuum furnaces for bulk degassing of SS components for accelerators have been developed at CAT. The furnace has a hot zone volume of 400 l which can attain a temperature of 700°C at 10^{-5} mbar.

The electron beam from 20 MeV microtron injector has been recently extracted. The synchrotron is fully assembled and all components well-aligned. All subsystems have been tested and this machine is expected to be operational in 1995. The transfer lines between the various machines have been assembled.

The electron beam from the synchrotron is being planned to be stored in Indus-1 in 1995. This will be a 450 MeV storage ring whose critical wavelength (defined as the median wavelength which divides the emitted synchrotron radiation energy into two equal parts) will be 61 Å. Useful flux can be obtained for wavelengths as short as 20 Å. The beam lines for the various experiments to be performed with Indus-1 are: (1) Photophysics (300–3000 Å), (2) Reflectivity measurements (40–1000 Å), (3) High-resolution spectroscopy, (4) Photoelectron spectroscopy, (5) L-edge spectroscopy, (6) EXAFS (100–1000 Å).

Indus-2 will have a critical wavelength of 4 Å from the bending magnets and a much lower wavelength of about 1 Å from the superconducting wiggler magnets. The major experimental programmes being planned for Indus-2 are: trace element analysis, lithography, small-angle scattering, diffraction, absorption-based spectroscopy, photoelectron spectroscopy and X-ray topography. The Indus-2 ring is expected to be commissioned in 1998.

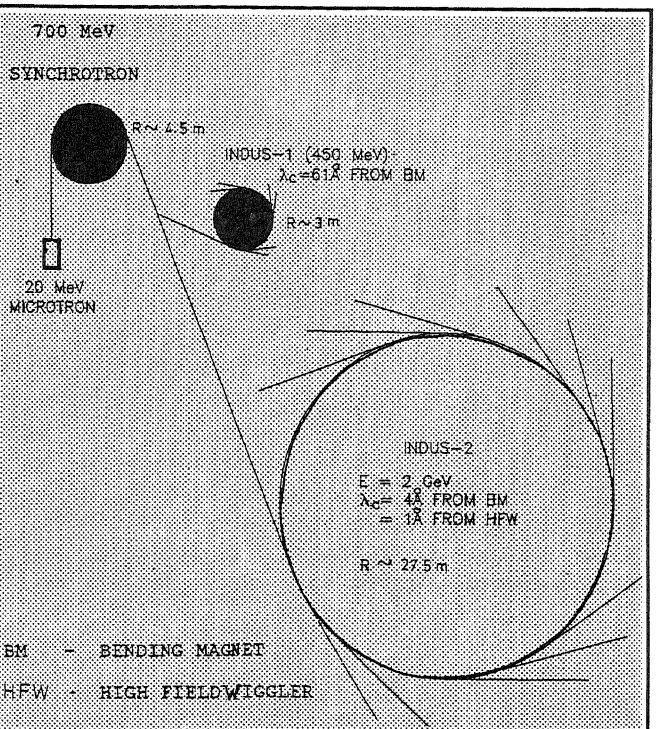

Figure B4. A schematic drawing of the synchrotron radiation source facility coming up at CAT, Indore.

search for the QGP. The BARC group will be involved in the design and the fabrication of the muon arm of PHENIX and also in the computer simulation related to this experiment.

The Indian scientists from TIFR and from Delhi and Chandigarh universities are also collaborating at the Fermi Lab, USA, on several frontier experiments and they are part of the teams which discovered recently the 'top quark'. In the future, India will also be collaborating in the currently planned highest-energy accelerator programme – the large hadron collider (LHC) – to be built in CERN.

Finally, the implication of all these laboratory experiments, in the context of the fundamental question of the origin of the universe a microsecond after the proposed 'big bang', when the universe must have consisted of quarks, gluons, leptons and photons, is in the postulation of the route to the synthesis of microcosmos and macrocosmos.

For several years, BARC has been collaborating with the Rutherford Appleton Laboratory in UK, which has a spallation neutron facility. The BARC group has built and installed a specialized neutron spectrometer in this centre – the so-called ΔT-window spectrometer – which uses the difference in temperature of two Be blocks to provide an ultrahigh energy resolution window for neutron inelastic scattering experiments.

Accelerator applications in industry and medicine

The charged-particle accelerators, primarily built for basic research in science, are being increasingly used for a variety of applications. Dedicated accelerators are also being built and operated for medical and industrial applications. The alpha particles from VECC have been used for characterization of (compound) semiconductors for oxygen. The helium-induced defects in refractory materials like Nb, Ta, W and V and in compound semiconductors like GaAs, GaP and InSb have been characterized. Information regarding migration of vacancies and the formation of vacancy clusters and helium bubbles has also been obtained from these studies. Some of these studies have direct implications for the mechanical and the metallurgical properties of refractory metals in a reactor environment. The helium jet recoil facility has been set up as a prelude to on-line isotope separation. Further, the alpha beams have been used for tribological investigations. Low-energy heavy-ion beams from Bhubaneswar have been used for materials science studies. Recently, using the proton backscattering tech-

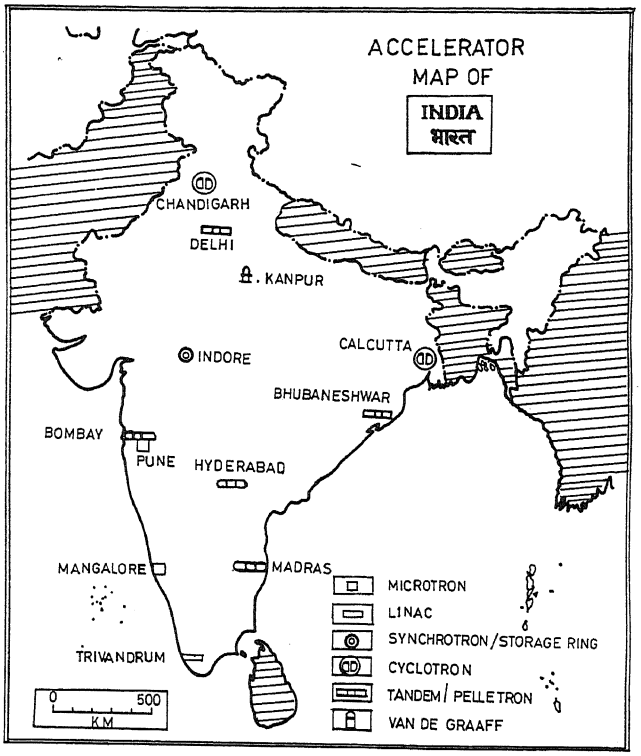

Figure 1. Accelerator map of India.

nique, the stoichiometry of thin VN films has been determined. Earlier, using the proton beam from Trombay Van de Graaff accelerator, the carbon build-up on the surface of a thorium target was estimated using the nuclear resonance technique. At the NSC, Delhi, a dedicated beam line has been developed for materials science studies, including high-energy heavy-ion irradiation to strengthen thin Cr films, characterization of superconducting films and bulk samples, and other ion-induced defects specifically involving high-energy heavy ions.

The use of particle accelerators in the study of problems in medicine and biology has been long recognized as a specific and powerful tool. The accelerators are being employed for both diagnosis and therapy. Certain specific radioisotopes like ^{67}Ga and ^{201}Tl required for accurate diagnosis of soft-tissue tumour and analysis of the functioning of the heart, respectively, can be produced only through nuclear reactions induced by charged particles from accelerators. Small quantities of ^{67}Ga are now routinely produced at VECC and used for diagnosis work in hospitals. Using the proton beam from VECC it is expected that the first batch of ^{201}Tl will be produced soon. A high-current captive cyclotron will be ideal to produce these isotopes at a reasonable cost. Trace element analysis of biological tissues, blood, etc., is another important area of investigation carried out using small-size accelerators.

The technique of radiation sterilization nowadays is used on a commercial scale in the manufacture of such products as disposable hypodermic syringes, blood transfusion kits, blood oxygenerators, Petri dishes, gloves, surgeon's needles and scalpels, besides some pharmaceutical products. Other areas include hygienization of sewage sludge and preservation of perishable food items. Electrons offer a substitute for gamma rays with the advantage of flexibility and inherent safety through on/off switching of the beam. A 10 MeV electron beam has been found to be suitable for this type of work. In India we are building a machine for this purpose. From economic considerations, a gamma ray source is favourable for industrial processing if source requirement does not exceed 1 million curies of ^{60}Co. The electrons complement the gamma rays from radioactive sources in many areas.

Radiation processing technology using electron accelerators has a pivotal role in an industrial environment. Low-energy electron accelerators having high beam intensity are being increasingly used in the radiation processing industry for a variety of applications.

At BARC, using the electron accelerator the following programmes are being pursued:

- Crosslinking of polythene 'O' rings for drum fittings – MOU with a Bombay firm for this application has been signed.
- Crosslinking of PVC/PE cables and wires for high performance and speciality applications.

There are plans to develop electron accelerators indigenously in BARC for this type of work.

For the radiation processing industry, plans are also under way at CAT to build a 750 keV, 20 kW electron accelerator mainly for the following items:

1. Radiation-processed crosslinked polyethylene cables and wires required by TV and computer manufacturers. Railways also import Rs 100 crores worth of these cables per annum.

2. Development of heat-shrinkable tubes. Telecommunication industry imports this item costing annually more than Rs 30 crores. CAT is also developing a 10 MeV, 15 kW electron Linac for industrial applications such as sterilization of medical products, irradiation of food products, etc. The dose rate available from such accelerators will be an order of magnitude higher than that from a typical ^{60}Co facility used for this purpose.

In order to demonstrate the economic viability of these various applications of accelerators in our country, CAT is thinking in terms of a medical and industrial accelerator centre which will be available to potential users for developing radiation-processing technology.

Use of radioactive sources like ^{60}Co for treatment of tumours is a well-known method. Recently, the electrons from low-energy electron accelerators are also being used for such treatment, particularly for superficial tumours. In India the radiation therapy based on accele-

rators is growing rapidly and at present there are about 20 odd electron accelerators operational in the country for this purpose. CAT has developed and operated a 20 MeV microtron as injector to a 700 MeV booster. Based on the experience gained on microtron, a 12 MeV microtron has been designed for applications like radiation physics studies and non-destructive testing and the same has been installed at Mangalore university. With addition of a Gantry, it is possible to make a radio therapy machine using the 12 MeV microtron. CAT is also at an advanced stage of building a 11 MeV cyclotron to produce short lived radio isotopes for positron emission tomography.

There exist also possibilities for use of accelerators in the nuclear fuel cycle, both for disposal of radioactive waste and for use as an 'energy amplifier' by introducing neutrons produced in spallation reactions into a subcritical assembly.

Summary

A possible strategy for accelerator-based research and applications can be summarized as follows:

- Research with existing facilities and utilization of the facilities for applied areas.
- Building new accelerator facilities for research and applications. Concentrating on reasonably large-size accelerators involving high technology but at moderate cost, which will enable work to be carried out in many frontier areas.
- International collaborations – physics research, participation in building accelerators and detector set-ups.

It is being realized that at least for research using big accelerators, cooperation amongst countries is very much needed not only for building expensive facilities but also for using the same. As we said before, no nation can any longer afford to go at such activities alone. However, our own national base has to be sufficiently strong and several national accelerator facilities are essential to provide this base. Our success in the international arena depends crucially on our expertise and competence built around our national facilities and development of manpower required to build and use the facilities both in India and abroad. A strong synthesis of the two programmes, national and international, should be the vision for our accelerator programme.

ACKNOWLEDGEMENTS. It is a pleasure to thank many of our colleagues from the DAE family and outside for providing valuable inputs to this report. In particular, we thank Dr D. D. Bhawalkar, Dr S. Gangadharan, Prof. S. N. Ganguli, Dr S. S. Kapoor, Mr S. S. Ramamurthi and Dr B. C. Sinha for valuable comments on the draft manuscript.

Recent fertility trends and prospects in India

K. Srinivasan

There is an increasing pace of fertility decline in large parts of the country in the recent years. Among the proximate determinants, the variables that have played a dominant role in fertility changes directly, in the Indian context are natural fertility and contraceptive use and indirectly, female literacy and infant mortality. For future, we can expect the TFR to be in the range of 2.9 to 3.0 by the year 2001 and 2.00 to 2.13 by the year 2011. The spurt in the female literacy rate will have a major impact on the future fertility levels.

THE most recent census[1] conducted in India in March 1991 placed her total population at 846.30 million, including an estimated figure of 7.72 million for the state of Jammu & Kashmir, where the census could not be conducted owing to political disturbances. Since 1951, when the first post-independence census was taken, the population of the country has increased by 485.22 million, more than twice the population that lived in the country in 1901, which was 238.40 million. During the decade 1981–1991 we have added to the country a whopping 162.97 million people, which is equal to the combined populations of France, Poland and the United Kingdom.

In terms of the rate of growth rather than numbers, during the decade 1981–91 the population has increased by 23.85%, or 2.12% annually, compared to 24.80%, or 2.20% annually, during the decade 1961–71. During the year 1991 the growth rate was 1.97%, almost the same as the average annual growth rate of 1.96% experienced 40 years earlier during the decade 1951–61. However, while the earlier growth rate was the result of a difference of an average crude birth of 42.4 and

K. Srinivasan is in the Population Foundation of India, B-28, Qutab Institutional Area, Tara Crescent, New Delhi 110 016, India.

death rate of 22.8 (birth and death rates measured for 1000 population per year) in the decade 1951–61, the 1991 growth rate was the result of a birth rate of 29.5 and a death rate of 9.8. Thus, during the 35-year period from 1956 to 1990 both the birth and death rates have declined by 13 points, keeping the growth rate almost unchanged. Unfortunately, this stagnation in the growth rate since 1961 has occurred, in spite of a strong awareness of the population problem at the national level since the country's first five-year plan in 1951, consistent antinatal policies and family planning programmes by the government to reduce the fertility levels in the population. An expenditure of approximately Rs 5550 crores has been spent on family planning since its inception until 1990.

This seems to be a paradoxical situation, in which the fertility declines have been tardy in a population when both at the people's level as well as at the governmental policy and planning level there has been a strong motivation to lower fertility levels and population growth rates. Many countries such as China, Thailand, Indonesia, Mexico and Brazil that launched their family planning programmes almost a decade later have achieved lower fertility levels than India. In 1991, China with a population size of 1155.5 million added to her numbers 16.52 million compared to 16.67 million added to India's. India has gained the unique distinction of being the country that adds the maximum number of people every year within her territory, surpassing China, which has a larger population. In order to understand the dynamics of this growth and prospects for the future, it is necessary to go into the components of population change, mortality, fertility and migration and the factors that have contributed to modifications in these components over time. Particularly relevant are the factors that influence the fertility levels in the Indian population; the component that holds the key to the demographic future of the country.

Fertility trends since 1970

Since 1970, fertility has been declining in most parts of the country as indicated by fertility measures. Table 1 presents data on two fertility measures, crude birth rate (CBR) and total fertility rate (TFR) and also on three important contributory factors to fertility change, viz. infant mortality rate (IMR), female literacy rate (FLR) and effective couple protection rate (ECPR or percentage of couples with wife in the age range 15–44 years effectively protected by a modern method of contraception from within the programme) in the country and in sixteen large states (that account for 95% of the country's population), for the years 1971, 1981 and 1991. The table also provides the CBR and IMR values for the latest available year 1993. This spans a period when the fertility transition has been occurring in the

Notes: (i) Figures indicate average rates over three consecutive years centred round the years 1971, 1981 and 1991. For example, CBR* for 1981 is the average of CBRs for 1980, 1981 and 1982. The rest of the figures are for the years 1971, 1981, 1991 and 1993.
(ii) TFR** for 1972 is based on SRS sample survey in 1972 and taken from ref. 6. The data are given for rural and urban areas and weighted by the 1971 rural–urban proportions in the census.
(iii) ECPR: Effective couple protection rate as on March 1971, 1981 and 1991.
(iv) FLR: Female literacy rate is percentage of literate among females aged 7 and above.
(v) 1993 figures are provisional estimates published by the Registrar General in September 1994.

Sources: (1) Various publications of the Sample Registration System by the Registrar General, including refs. 4 and 5.
(2) Ref. 3.

country. The fertility and mortality figures have been compiled from the official publications[2–6] of the Registrar General of India from the Sample Registration System, the female literacy rates from the 1971, 1981 and 1991 censuses and ECPR values from the Family Planning Year Books[7,8] put out by the Ministry of Health and Family Welfare. Since the Sample Registration System (SRS) is a dual record system based on data compiled on births and deaths from a sample of villages and urban blocks in the country (and though the sample sizes are fairly large enough to estimate fertility and mortality levels within 5% coefficient of variation), we have used three-year averages of vital rates, wherever available, centred around 1971, 1981 and 1991, especially for the study of long-term trends in these rates.

The CBR, defined as number of births per 1000 population per year, has declined from 37.2 in 1971 to 33.8 in 1981 and 28.7 by 1993. Thus, the annual decline in the CBR during 1981–93 was 0.425 compared to 0.340 during 1971–81, or 25% more than the earlier period. In 1993, among the states the CBR has ranged from a minimum of 17.4 in Kerala to a maximum of 36.2 in Uttar Pradesh. The CBR values for the rural and urban areas for 1993 for the country as a whole were 30.4 and 23.7, respectively. In Kerala the rural and urban CBR values were 17.5 and 17.3 respectively, while in UP they were 37.2 and 31.1 respectively.

It has been found that as fertility levels decline, the differences in fertility between the rural and urban areas as well as between the other segments of the population, such as by religion, caste or income categories, tend to narrow down and fertility becomes more homogeneous across the population. The more recently conducted National Family Health Survey (NFHS) that covered a representative sample of 88,562 households from most of the country has estimated the CBR for 1992–93 at 28.9, with 30.7 in rural areas and 28.9 in urban areas, which varied from a minimum of 17.2 in Goa and 19.6 in Kerala to a maximum of 36.0 in Uttar Pradesh, figures that are close to the estimates from the SRS, and provide independent validation to the SRS figures.

The changes in fertility or any variable can also be studied in relation to the progress made towards reaching the long-term goal set for different measures by an 'index of progress' (IP), by relating the actual decline in a fertility measure over a period of time to the required decline to reach the specified long-term goal in the measure. The recently appointed 'Expert Group

All India	21.0	25.9	46.9	22.6	25.8	48.4	23.2	26.3	49.5	21.2	35.6	56.8

Notes: (i) The percentage progress made is measured as a ratio of the change in given period to the required change to reach the goal. For example the progress in CBR during 1971–81 is 100 * (B71 – B81)/(B71 – 21), where B71 and B81 are the CBRs for 1971 and 1981 and 21 is long-term goal for CBR.

(ii) The percentage progress made during two periods for the same area is additive; i.e. the progress made during 1971–91 is the sum of the progress made during 1971–81 and 1981–91.

(iii) *For TFR 1971–81 and 1971–91 the changes are from 1972 to 1981 and 1972 to 1991. The rest of the figures are for years 1971, 1981, 1991 and 1993.
**The ratio of change in 1981–91 to 1971–81 is not computed if there is an increase in CBR, TFR or IMR values during a period.

(iv) The long-term goals for all the states are assumed to be the same though they may be achieved in different years.

Computed from figures given in Table 1.

on Population Policy' under the chairmanship of M. S. Swaminathan that submitted its report[9] in May 1994 has recommended the long-term demographic goals for TFR as 2.1 and IMR of 30 infant deaths per 1000 live births to be achieved by the year 2010. The Eighth-Plan document (1992–97) has recommended a long-term goal for a CBR of 21 to be reached by 2006–11, that implies an effective couple protection rate (ECPR) of 70%. The IP with regard to decline in the CBR value during 1971–91 towards the long-term goal of 21 can be measured as 100 × (CBR-71 minus CBR-91)/(CBR-71 minus 21).

Table 2 provides data on the IP values computed for major states for selected measures of fertility, mortality and contraceptive use in relation to their long-term goals. For the country as a whole the IP value for CBR during 1971–81 was 21% [100 * (37.2 – 33.8)/(37.2 – 21)], during 1981–91 was 28% and during 1981–91 was [100 * (33.8 – 29.5)/(37.2 – 21)]. Thus, during the whole period 1971–91, IP was slightly less than half (49%) towards the long-term goal of 21 set for CBR and the progress towards the goal during 1981–91 was 33% more than in the earlier decade. The IP values are studied only for the periods 1971–91 since we preferred to use three-year average values that are statistically more reliable around 1971, 1981 and 1991.

The decline in fertility during the period 1971–91 measured in terms of TFR, a more refined measure of fertility that denotes the average number of children born to a woman in her entire reproductive span assuming that she experiences the level of age-specific fertility rate obtained in a given year or period, is more pronounced. In 1991, TFR (average of 1991–93 values) was 3.7 births per woman in the country as a whole, ranging from a low of 1.8 in Kerala to a maximum of 5.2 in Uttar Pradesh. In the country as a whole, TFR declined from 5.2 in 1972 to 4.5 in 1981 to 3.7 in 1991. IP towards the long-term goal of 2.1 for TFR was found to be 49% during 1971–91, made up of 23% during 1972–81 and 26% during 1981–91. In this connection, it is worth mentioning that, as a starting point for the measure of TFR, we have used the estimate obtained from the Special Survey on Fertility and Mortality[10] conducted by the Registrar General in 1973, providing estimates for 1972, since those computed from the routine SRS, during the early seventies are considered to be underestimates[11]. Thus, while we have the change in TFR measured for a period of nine years during 1972–91, it is for a period of ten years during 1981–91.

IP in TFR has been more than 100% in Kerala, implying that the state had already achieved by 1991 the goal set for the country for 2010. The IP value was 96% in Tamil Nadu, which had almost reached the replacement level of fertility by 1991. It is, however, less than 50% in the states of Bihar, Madhya Pradesh, Rajasthan and Uttar Pradesh, states that are euphemistically referred to as 'Bimaru' states. The problem of fertility control is thus largely confined to the four large Hindi-speaking states in the north. Figures 1 and 2 provide a graphic presentation of the states arranged according to their progress or IP values on CBR and TFR during 1971–81 (1972–81 for TFR) and 1981–91. From Table 2 it can be seen that the pace of change during 1981–91 is more than during 1971–81 excepting in Assam, Karnataka, Punjab and UP. In other words, there is an increasing pace of fertility decline in large parts of the country in the recent years.

Factors contributing to fertility change

Earlier studies on factors associated with fertility levels and changes in India and other developing countries have identified the determinants at two levels, viz.

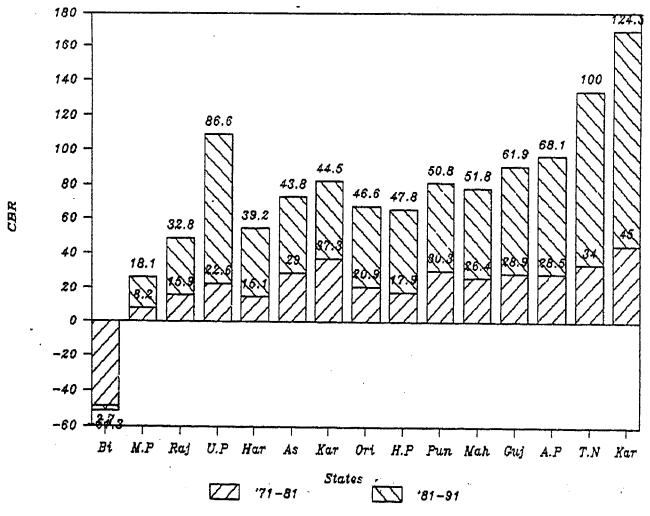

Figure 1. Percentage progress in CBR to goal 21 during 1971–81 and 1981–91.

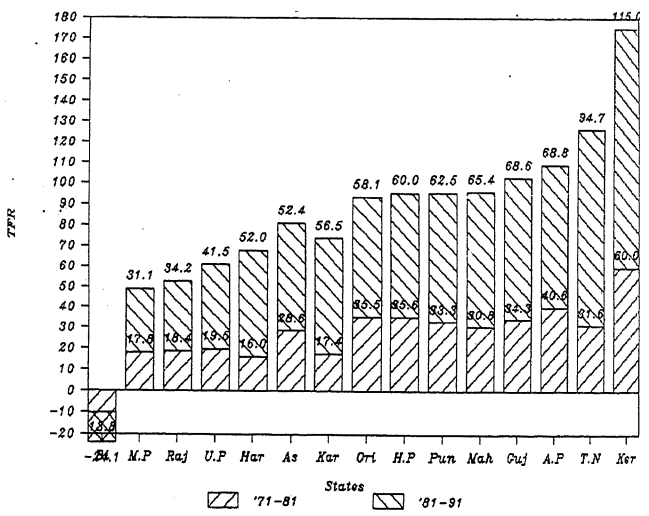

Figure 2. Percentage progress in TFR to goal 2.1 during 1971–81 and 1981–91.

proximate determinants and factors influencing proximate determinants. The proximate determinants of fertility are those intermediate variables through changes in any of which any modification in human fertility has to be brought about, viz. (a) *natural fertility* (NF), (b) *nuptiality* (NU), (c) *contraceptive use* (CU) and (d) *abortions* (AB) and three directly manipulable modernizing factors that are causally more distant from fertility as compared to the proximate variables, but that affect fertility powerfully through one or more of the proximate determinants, viz. (a) *family planning programmes* (FPP), (b) *female literacy* (FLR) and (c) *infant mortality* (IMR)[12–14]. Among the proximate determinants, the variables that have played a dominant role in fertility changes (increase or decrease) directly in the past in the Indian context are natural fertility and contraceptive use and indirectly, female literacy and infant mortality. We will briefly discuss their contributions one by one in the Indian context, and what they portend for the future of fertility in this country. To discuss the contributions of all the proximate determinants and their determinants will go beyond the scope of this article.

Proximate determinants of fertility

Natural fertility. Natural fertility is defined as the fertility of a married couple in the absence of any deliberate control to increase the spacing between children or to limit the family size. In India, the natural fertility has been historically quite low, probably the lowest in the world. It was only about six births per woman, or just 60% of the number observed in European populations in the eighteenth and nineteenth centuries, when they did not practice any contraception. Fertility levels have been kept in check in India by various social and cultural practices and to some extent are attributable to the high prevalence of febrile diseases such as tuberculosis, malaria and malnutrition that reduced the biological fecundity and in some cases caused infertility in the couples. Despite the tradition of early and universal marriage, various religious and cultural restrictions on sex, prohibitions against widow remarriage, prolonged breast feeding contributed to low natural fertility. With modernization gaining rapid momentum after independence, these traditional and cultural practices that kept the natural fertility of Indian population at low levels for centuries have weakened considerably. Further, the increases in life expectancy and improvements in nutritional and health status attributable to green revolution and control of many communicable diseases, the duration of married life that a woman spends in the reproductive period has increased rapidly and the natural fertility levels have increased steadily to approximately 7 children in the seventies to 9 in the eighties[14–16]. From a detailed analysis of data on age-specific marital fertility rates compiled from two large-scale sample surveys conducted in 1959 and 1972 in 11 major states in India, Srinivasan and Jejeebhoy[17] observed:

'The results consistently indicate an increase in the total marital fertility rates in eight of the eleven states (the exceptions being Kerala, Orissa and Punjab) between 1959 and 1972. The most striking increases in marital fertility have been observed in those states where there has been practically no prevalence of contraception. The increase is 28% in Uttar Pradesh, 26% in Rajasthan, 13% in Madhya Pradesh and all these states were practically under natural fertility conditions . . .' (p. 103).

This tempo of rise in natural fertility initiated in the early sixties continued into the seventies and in the state of Bihar the rising trend is observed even in the eighties. Pathak and Ram[16], using indirect techniques, estimate the level of natural fertility to be slightly more than 9 children in the eighties. Thus, it has to be recognized that whatever decline in the birth rate that has occurred in India has taken place in the context of an almost steady rise in the natural fertility levels of the population to about one-and-a-half times the initial level. The plateauing of this rise seems to have occurred in the eighties, and there may not be any further fertility-increasing effects of modernization. It is to be noted that in the absence of the vigorous family planning programme that we had in the past few decades, the observed fertility levels in the Indian population would have risen considerably.

Contraceptive use. India can take legitimate pride in the fact that it is the first country in the world, developed or developing, to realize at the governmental level the extent of hurdles to development posed because of rapid population growth and launch an official programme of family planning as early as 1951 to control fertility as a part of the first five-year plan (1951–56). The governmental emphasis on the programme has accelerated over the years with plan expenditure on the programme rising sharply from a meagre Rs 14.5 lakhs in the first plan to 2304.5 crores in the seventh plan period, 1985–90. The current level of annual expenditure on the programme incurred by the states and the centre (plan and non-plan), mostly by the centre, is about 1000 crores per year. In 1991, there were about 131,000 subcentres, 22,060 Primary Health Centres, 1930 Community Health Centres, 1515 Urban Family Welfare Centres and about 554 district/state-level hospitals providing family planning services across the length and breadth of the country.

The impact of such a massive expansion of activities in the field of family planning over the years is seen from the data on the increasing prevalence of contraceptive use in the country (given in Table 1). The effective couple protection rate (ECPR) or the percentage of married women in the reproductive ages (15–44)

protected effectively from pregnancy by a modern method of contraception has increased from almost zero level in the late fifties, to 10.1% in 1971, 22.0% in 1981 and 44.1% in 1991. In actual numbers, 64.07 million couples are effectively protected by contraception under the programme. Out of this 44.1% of couples using contraception effectively in 1991, 30.3% (or 68% of those protected) have been protected by sterilization (of the husband or wife), 6.7% (or 15% of those protected) by IUD and 7.2% (17% of those protected) by other methods that include oral pills, condoms, injectibles and others. Thus, sterilization, vasectomy until 1976 and tubectomy thereafter, has been the dominant method promoted by the programme from its very inception and accounts for the bulk of the protection in the country.

In 1991 among the states the ECPR values ranged from a low of 26.0% in Bihar to 75.8% in Punjab. The IP values in ECPR furnished in Table 2 reveal that while towards the long-term goal of achieving 70% in the ECPR values, only 21.2% progress was made during 1971–81; during 1981–91, 35.6% was made and the ratio of progress between the two decades is thus 1.7. This ratio has ranged from 7.1 in Punjab (where the progress during the 1971–81 decade was poor) to 0.7 in Assam. In all the states other than Assam, the IP values in 1981–91 are higher than in the previous decade, indicating a rapid acceleration in the use of contraception in recent years. A considerable degree of caution has to be exercised in projecting this trend to future years because of the various assumptions made by the Department of Family Welfare in the computation of ECPR values. However, even if we assume that the quantum of increase in the ECPR values experienced during 1981–91, i.e. 21.8%, will be maintained during 1991–2001, it will lead to an ECPR level of 65.1% in the year 2001 for the country as a whole, a level quite close to what is required to realize the replacement level of fertility. It has to be realized that further increase in ECPR values has to come mostly from the hitherto poorly performing states of Assam, Bihar, Rajasthan, Orissa, Madhya Pradesh and Uttar Pradesh, that have performed below the national average in 1991 and that have about half the population of the country.

An additional positive feature of changes occurring in the country during the past two decades is the reduction in the gender bias of the population. The people of this country have for centuries placed undue emphasis on the male child and this gender bias has been institutionalized in a number of ways through religion and other social institutions. The female child has been given a secondary position in the family and society in all aspects, including education, property ownership, health care and decision making. This bias seems to be breaking down in recent times. The data collected in a large-scale survey[18] conducted during 1988–89 by the Operations Research Group (ORG), Baroda, to study the levels, trends and determinants of contraceptive use in the country revealed that among couples in the reproductive ages (wife in the age range 15–44), among those with two surviving children, both daughters, 35.6% were using a modern method of contraception and 15.6% have undergone sterilization. Even among those with no surviving children 12.0% were using a modern method of contraception. Figure 1 provides the contraceptive prevalence rate by numbers of surviving children and surviving sons. While there is an increased use of contraception among couples with more sons, the practice among those without any son has also risen substantially.

One of the major reasons for the reduced impact of the family planning programme on the fertility levels in India is the undue emphasis placed by the programme on the method of sterilization, vasectomy for males until 1976 and tubectomy for females thereafter. Since this is largely an irreversible and permanent method, couples prefer to adopt it after they have reached the desired family size and at older ages and higher parities. Couples who wanted to space their children and keep the option of their fertility open did not take to these methods and invariably landed up with a larger family size than what they would have liked to have if good temporary, reversible methods were made available to them from the early years of the programme. The sterilization programme has been like 'locking the stables after the horses have been bolted away'. Further, with the rise in natural fertility pushing up the fertility levels of the younger married couples (because of relaxation of traditional checks on fertility and control of febrile diseases and better nutrition) only the tail end of the fertility curve was affected by the programme while at the peak ages of fertility, viz. 20–29 years, the marital fertility was rising during the sixties and seventies. Since the rising phase of natural fertility had largely been completed by the late eighties (possibly with the exception of Bihar) and increasing emphasis is being placed on the spacing methods in recent years, the fertility impact of the programme is likely to increase in the coming years with more and more younger women coming to use modern methods of contraception.

Another indication of major changes taking place in the population is on the extent to which couples have reported not desiring any more children at different stages of their family building in the early eighties and nineties. In a large-scale sample survey conducted by the ORG, Baroda, in 1980–81, the percentage of eligible couples who did not desire any additional children in the country as a whole was 1.0, 12.7, 43.3, 68.7 and 83.7, among married women with 0, 1, 2, 3 and 4 or more living children respectively. The corresponding percentages in the 1992–93 National Family Health

Survey[19] are 2.3, 19.1, 61.8, 78.0 and 83.6, respectively. These figures include a sizeable proportion who have already resorted to sterilization to avoid further child bearing. Particularly impressive is the rise in the proportion of women with two living children not wanting any more children, which is 62%, half of whom had already undergone sterilization.

Nonproximate developmental factors in fertility change

Declines in infant mortality. Detailed studies of the demographic transition in the developed and developing countries have revealed a strong link between declines in the mortality levels of a population, especially in the infant and child mortality and fertility levels. The well-known 'theory of demographic transition' is based on the empirical evidence from a number of countries that have successfully achieved the transition from a high-fertility–high-mortality to low-fertility–low-mortality regime. In all these cases, mortality declines always preceded fertility declines with a time lag and the pace of mortality decline determined the pace and timing of fertility decline even in the absence of any organized contraceptive services. Family planning programmes assist and expedite the pace of fertility decline once they have commenced as a part of the multiphasic social response to earlier mortality declines[20].

Life expectancy in India has improved substantially from the third decade of this century from an estimated 20 years in 1921 to 60 years in 1991. During the four decades 1941–51 to 1981–91, life expectancy rose by 25 years with about 0.6 years added to an Indian's life each year. Credit for this considerable achievement goes to various public health measures undertaken by the central and state governments. Life expectancy varies considerably among the states, with 71.1 years in Kerala to 49.6 years in Uttar Pradesh for the quinquennium 1986–91. The crude death rate has declined from 47.2 fatalities per thousand population during 1911–21 to 9.3 in 1993. The decline in the death rate seems to have begun after 1921, and since 1951 has been quite rapid. Infant mortality rate (IMR; deaths of children below age one year per 1000 live births), was estimated at 222 for the decade 1901–11, declined to 129 for 1961–71 and to 74 by 1993. There are sizeable interstate variations in the IMR values. In 1993, IMR ranged from 110 in Orissa to 13 in Kerala. There are also rural–urban differentials in the IMR values, 82 in the rural areas compared to 45 in the urban areas in 1993. The differentials can be largely attributed to the prevalence of better health and medical care facilities in states such as Kerala, Maharashtra, Tamil Nadu and West Bengal and to the relative concentration of these facilities in the urban areas in most states. It has been observed that as the infant mortality levels decline, rural–urban differentials tend to narrow down. For example, in Kerala, in 1993 the rural IMR was 15 compared to 8 in the urban areas while in Orissa the rural rate was 115 compared to 69 in urban areas. The reduced differentials in mortality seem to be an indicator of the extent of dispersion of basic health services across the country. The declines are attributable to the control of various infectious and communicable diseases that had been taking heavy tolls among children. Concomitantly, there is a tendency for mortality rates among the adults and the elderly to rise because of increases in noncommunicable diseases, including cardiovascular problems, cancer and accidents. The shift from the age pattern of deaths from younger to older ages and predominantly infectious to noninfectious diseases has been termed as the 'epidemiological transition' and many states in India are almost completing such a transition. The basic requirement for a sustained fertility transition, viz. decline in the mortality levels, especially the infant and child mortality levels, is present in the Indian population with varying degrees of success in different states. The states that have achieved faster declines in mortality levels such as Kerala have achieved lower fertility levels well ahead of the other states.

Analysing the progress made in the reduction of IMR values towards the long-term goal of 30 infant deaths per 1000 live births, through the index of IP given in Table 2, it is found that in the country as a whole the IP during 1971–91 is about 50%, with 23% during 1971–81 and 26% during 1981–91. There is thus a 13% acceleration in the pace of decline in IMR values in recent years. Figure 3 gives a graphic representation of IP values in different states during 1971–81 and 1971–91. The minimum decline has been recorded in the state of Orissa and more than 50% IP values are found in

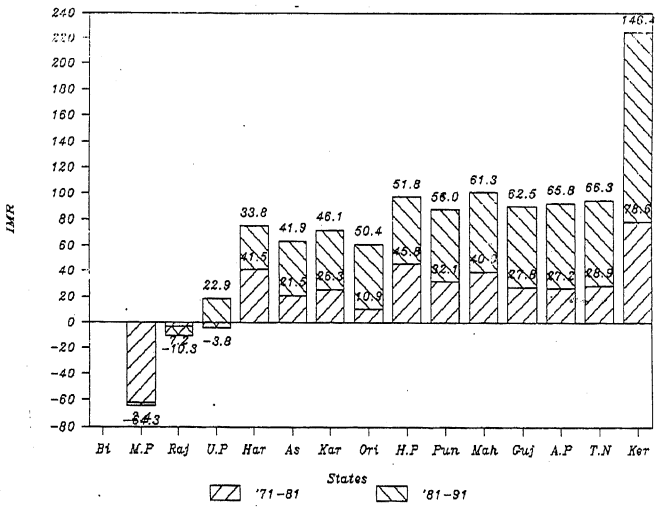

Figure 3. Percentage progress of IMR to goal 30 during 1971–81 and 1981–91.

the states of Assam, Himachal Pradesh, Kerala, Maharashtra, Punjab, Tamil Nadu and Uttar Pradesh. It is found that among the larger states only the state of Kerala has already achieved both the fertility and infant mortality goals set for 2010, with a TFR of 1.8 CBR of 18.3 and IMR of 16 by 1991. While Tamil Nadu has almost reached the fertility goals with TFR of 2.2 and CBR of 20.8 by 1991, its infant mortality rate of 56 in 1993 is still distant from the goal of 30. However, Tamil Nadu and Punjab have achieved the IMR goals set by the earlier National Health Policy of 1983, wherein the goal was to reach a level of 60 or less by the year 2000. Thus, the picture that emerges from an analysis of the changes in the IMR values between 1971 and 1991 is that the tempo of change (decline) in the IMR values has accelerated in the recent decade 1981–91 compared to the earlier decade and this is bound to have an effect in accelerating the pace of decline in fertility in the coming years.

Female literacy. One of the major determinants of demographic transition leading to declines in infant and child mortality, overall mortality, increase in age at marriage, rise in use of modern methods of contraception, declines in the fertility levels of the population and development *per se* is education of women. Societies that have achieved universal literacy of females and higher educational attainments for women have all recorded more rapid demographic transition. The fertility transition in China, Sri Lanka and Kerala state in India all bear ample testimony to the above conclusion. This is demonstrated strongly by data in Table 1, wherein a strong negative association between female literacy rate and fertility levels is observed in all the three census years (e.g. -0.85 in 1991).

Literacy rate for females aged 7 and above increased from 22.9% in 1971 to 29.8% in 1981 to 39.4% in 1991. In 1991 it ranged from a high of 86.9% in Kerala to a low of 20.8% in Rajasthan. While the literacy rate both among the males and females has been rising over the decades, the absolute number of illiterate females in the population aged 7 and over has been increasing steadily, to 126.7 million in 1991, with an increase of 5.7 million during the decade 1981–91. Almost 80% of the illiterate female population of the country (about 96 million) are concentrated in the four large Hindi-speaking states of Bihar, Madhya Pradesh, Rajasthan and Uttar Pradesh.

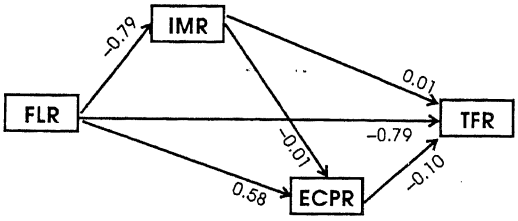

Figure 4. Path model.

A multivariate model

The combined and separate effects of three of the four contributory factors discussed above, viz. FLR, IMR, ECPR on the TFR can be assessed by a simple path model. We are not in a position to take account of the factor of natural fertility since we do not have direct data on the same and any measure of natural fertility has to be derived only indirectly from the observed fertility measures and the extent of the use of contraception.

In the path model (Figure 4) each variable is assumed to be influenced only by others posited to the left of it and not by any on its right. In the above model the TFR is assumed to be influenced by all the three factors – FLR, IMR and ECPR; ECPR is assumed to be influenced by IMR and FLR, and IMR by FLR, in addition to the other factors not explicitly entering into the model but affecting the variability of the factors. The zero-order correlation coefficients among the four variables for the years 1981 and 1991 are furnished in Table 3, where the figures in the upper triangle of the matrix provide the coefficients for 1981 and the lower triangle for 1991. Using the data for 1991 given in Table 1 the following regression equations emerge by applying the simple least-square method of estimation. All the correlation coefficients are statistically significant and reveal the strong interrelationships that exist among them.

Using the above path model and standardized variables, the regression equations among the variables are as follows. In this case the regression coefficients are the path coefficients, as per the above causal model.

$$\text{TFR} = -0.79 * \text{FLR} + 0.01 * \text{IMR} - 0.10 * \text{ECPR}, \quad (1)$$
$$n = 16 \text{ and } R\text{–squared} = 0.74,$$

$$\text{ECPR} = 0.58 * \text{FLR} - 0.01 * \text{IMR}, \quad (2)$$
$$n = 16 \text{ and } R\text{–squared} = 0.35,$$

$$\text{IMR} = -0.79 * \text{FLR}, \quad (3)$$
$$n = 16 \text{ and } R\text{–squared} = 0.63.$$

Table 3. Correlation matrix of selected variables in 1991

TFR	1.00000			
IMR	0.68190	1.00000		
ECPR	–0.56962	0.47290	1.00000	
FLR	–0.85386	0.79412	0.58982	1.00000

Critical value (1-tail, 0.05) = ±0.42706
(2-tail, 0.05) = ±0.49580

$n = 16$

The above analysis reveals that 74% of the variability in TFR is explained by the three factors considered but among them only FLR has a significant direct impact on fertility with a very high magnitude path coefficient of -0.79. Similarly, FLR has a statistically significant impact on the IMR as well as on the ECPR value. Thus, in the present context FLR seems to have a major effect, directly on TFR through its effect on age at marriage, use of induced abortions, etc., and indirectly on marital fertility rate through better acceptance of contraception from within the programme.

Interestingly, repeating the above analysis with the data for 1981 and using the standardized variables, the following equations emerge. Since the regression coefficients are based on standardized variables and they are the path coefficients, they permit comparison of the effects of variables over time and among the different variables.

$$\text{TFR} = -0.28 * \text{FLR} + 0.39 * \text{IMR} - 0.38 * \text{ECPR}, \quad (4)$$
$$n = 15 \text{ and } R\text{–squared} = 0.82,$$

$$\text{ECPR} = 0.63 * \text{FLR} - 0.01 * \text{IMR}, \quad (5)$$
$$n = 15 \text{ and } R\text{–squared} = 0.41,$$

$$\text{IMR} = -0.78 * \text{FLR}, \quad (6)$$
$$n = 15 \text{ and } R\text{–squared} = 0.78.$$

Comparison of the results for 1991 and 1981 reveals that the effect of FLR on IMR has remained stable and significant over time with over 75% of variance in IMR value explained by FLR. The effect of FLR on ECPR has declined over time. With regard to their direct impact on TFR values, while IMR and ECPR were having a significant effect and FLR not a significant effect in 1981, the effects are reversed in 1991 with only FLR having significant effect on fertility in 1991. This suggests that in the coming years more than the family planning programme, which offers the family planning services, education of women may play a more crucial role in shaping the fertility values in the country. The increased emphasis placed by the state and central governments on the literacy programme through the national literacy campaigns with emphasis on female literacy will have its direct and indirect impact of the fertility levels in the coming years.

Future prospects for fertility

As with any prediction exercises of future human behaviour, prediction of future fertility levels in India is a highly probabilistic endeavour, with the level of uncertainty increasing with the time span over which the predictions are made and the smaller level of population aggregation at which it is made. Predictions over a longer time span and for smaller geographic or population size zones are more loaded with uncertainty than predictions over a shorter time span and for the country as a whole.

Let us undertake this venture at two levels, one a simple and the other a more complex modelling. For example, TFR was 3.7 in 1991, 4.5 in 1981 and 5.2 in 1972.

During 1972–81 it declined by 0.7 points (5.2 to 4.7) while during 1981–91 by 0.8 points (4.5 to 3.7), implying that the reduction in TFR over the 20-year period was almost at the rate of 0.8 points per decade. If this trend of decline continues into the future, i.e. at 0.08 point reduction per year, then the TFR will be 2.9 by 2001 ($3.7 - 0.8$). Similarly, with regard to CBR, if we assume that the pace of decline during 1981–91 will continue into the future, the expected value in 2001 will be 25.5 ($29.6 - 4.2$). These are simplistic extrapolations of earlier trends.

We can make the projections of fertility a bit more complex and indirect by using regression of TFR on the important contributory factors discussed above, viz. IMR, FLR and ECPR and using the projected values of the predictors. The regression equation using the actual values (rather than standardized values as needed for the path model), based on the 1991 data is:

$$\text{TFR} = 5.6324 + 0.0004 * \text{IMR} - 0.0066 * \text{ECPR} - 0.0446 * \text{FLR} \quad (7)$$
(multiple $R = 0.8578$).

The projected values of the three predictors by the year 2001 can be obtained as follows under as realistic and conservative an approach as possible.

1. *Infant mortality rate.* For the country as a whole IMR has declined from 129 in 1971 to 106 in 1981 and to 80 in 1991. The governments at the state and central level have, in recent years, intensified their child immunization programmes throughout the country in collaboration with and assistance from the UNICEF under the Child Survival and Safe Motherhood Programmes (CSSM). There has also been tremendous media blitz on the need for immunization, and child care and nutrition, and we can expect, on a conservative assumption, that in the next ten years, during 1991–2001, the quantum of decline in the IMR values will be of the same magnitude as in the decade 1981–91, i.e. a decline by 26 points. Under this assumption we can project the IMR value in 2001 at 54.

2. *Effective couple protection rate.* For the country as a whole the ECPR values have increased during the decade 1981–91 by 21.3 points from 22.8 to 44.1%. With the increased emphasis on spacing methods and concern for improvement of the quality of services, in recent years, we can expect this tempo to be maintained in the period 1991–2001 and we can expect ECPR to increase to 65% ($44 + 21$) by the year 2001. This assumption seems to be a bit optimistic and hence we will

make another assumption, on the more conservative side, 55%, in which we assume that the increase in the ECPR value is only 11%, slightly less than what was achieved in the decade 1971–81, which was 12.7%. We will thus have two assumptions of 55% and 65% for the ECPR values by the year 2001.

3. *Female literacy rate.* FLR is going to be the cutting edge of demographic change, especially fertility transition, in this country in the years to come. It has increased from 22.9% in 1971 to 29.8% in 1981, to 39.4% in 1991, or by a factor of 1.30 and 1.32 in the two decades. In recent years there has been considerable emphasis on the literacy of women and the girl child through the national literacy campaigns, mid-day meal schemes for school children, and various mass media programmes. I expect such a national movement to increase FLR exponentially by the same factor between 1981 and 1991. In other words, I expect the literacy rate among females aged 7 and over by the year 2001 to be FLR-91 * (FLR-91/FLR-81) or 52.0.

Under these assumptions of future changes in the predictors of fertility, i.e. IMR of 54, ECPR of 65 or 55 and FLR of 52 by 2001, using equation (7) we get TFR in 2001 as 2.91 or 2.97, with ECPR at 65 or 55, respectively. With the same reasoning as above, if we extrapolate the predictor values to 2001, IMR will be 28, ECPR will be 86 or 66 and FLR will be 69 by that year. Using these values for the predictors in the regression equation we get a TFR for 2011 as 2.00 or 2.13 for the two ECPR alternatives. The long-term goal of TFR of 2.1 to be reached by the year 2011 will definitely be reached under these assumptions. Thus, we can expect TFR to be in the range 2.9–3.0 by the year 2001 and 2.00–2.13 by the year 2011. If there is going to be a spurt in FLR in the coming years (which is not unlikely), it will have a major impact on the future fertility levels. It has to be realized that a 20% point increase in the FLR value will reduce TFR by one child.

I have not discussed in this exercise the various difficulties that are going to be faced in the programmes for reduction of IMR, increase in the use of contraception within the programme (ECPR) or raising the FLR, and these are by no means to be underestimated. The need to intensify our efforts on immunization and child nutrition programmes, improvements in the quality of services offered in the maternal, child health and family planning programmes and achievement of universal literacy for all with emphasis on the schooling of the female child are to be emphasized at the risk of repetition. However, I wish to point out that fertility has started its downward trend in this country, that the pace of decline is accelerating in the past decade and that the changes in three important determinants of fertility, IMR, ECPR and FLR, are also changing fast enough to have synergistic dampening effect on fertility and that the goal of replacement level of fertility or TFR of 2.1 will definitely be reached by the year 2010 as targeted in the recent population policy document, if not earlier.

Adaptive features of the predatory ladybird beetles in uncertain and competitive habitats

B. K. Agarwala and S. Bhattacharya

Department of Life Science, Tripura University, Agartala 799 004, India

The predatory species of ladybird beetles forage in habitats where aphid colonies show a patchy distribution in space and time. In an uncertain environment the numerical response of the females to aphid density suffers from unstable food source and sharing of the habitat by different ladybird species. As a result, the reproductive effort of a predatory ladybird species is threatened by the intraspecific and interspecific competitions. It is imperative that ladybird species should synchronize their reproduction and development of progeny with phenology of prey populations in order to overcome the risks of their habitats. This paper brings together the results of several studies to present an account of the adaptive mechanisms evolved by the predatory species of ladybirds to cope with the risks inherent in their life cycle.

MANY species of ladybird beetles (Insecta, Coleoptera, Coccinellidae) are predators of aphids, and other insects and mites. Some of these ladybird beetles are regarded as important natural control agents because of their ability to feed on large quantities of aphids[1]. Several species of aphids are a menace to agriculture and horticulture[2–4]. As part of integrated pest management strategy, increasing efforts are being made to understand the ecology of predatory ladybird beetles in the development of successful biological control of pest aphids[5,6].

Field studies suggest that larvae and adults of most ladybird species search plant surfaces at random and concentrate their efforts on the restricted area where a prey is captured, i.e. they show a positive prey-taxis[7,8]. As a consequence of this foraging behavior, ladybird beetles manage to exploit aphid colonies that have a patchy distribution and a short life span[4]. This tendency results in an aggregation of either conspecific larvae and adults or other species of ladybirds that share the same habitat and, therefore, are likely to interact with one another[1,9,10]. In such a competitive environment, it is possible that the reproductive output of individual species is threatened by one or more of the following risks:

1. temporary nature of food supply – for instance, sudden collapse of aphid colonies before larval development is completed;
2. cannibalism of eggs and larvae; and
3. interspecific predation.

How predatory ladybirds overcome these inherent risks is the question this paper seeks to answer by reviewing the adaptive features of their reproductive behaviour, interspecific predations and cannibalism.

Reproductive behaviour

The reproductive behaviour of aphidophagous ladybird beetles is guided by the following facts: (i) the aphid populations persist for a relatively short period of time[4]; (ii) the developmental time of ladybirds and the life span of aphid colonies are approximately equivalent[11]. and (iii) there is necessity of avoiding any competition between larvae for the limited food resource. Further, it has been shown that the newly born larvae need a higher aphid density to survive than the older ones, and that feeding success of these young larvae is negatively correlated to prey size[12]. In these conditions it is conceivable that the life cycle of ladybirds should synchronize with the development of prey populations.

Field observations based on survey of different habitats occupied by *Adalia bipunctata* L. show that eggs are generally laid in aphid colonies early in their development[12,13] and oviposition is limited to a short period of the early phase of population growth[14]. Similar results have been obtained for another ladybird species *Coccinella transversalis* (Fabricius) in bean crops infested by *Aphis craccivora* Koch[1] (Figures 1 and 2).

Laboratory observations further suggest that oviposition is strongly inhibited by the presence of conspecific larvae or other females[14] (Figure 3). Such females not only produced less number of eggs but also took more time to lay eggs than control females. Interestingly, however, ovipositing females did not respond adversely to the presence of their own pupae and eggs. The possible cause of such an interference could be some form of signal, as reported in parasitoids[5], to the ovipositing female, who gets the indication that the size of aphid colony is not suitable for egg laying.

A recent study[6] suggests that an adult ladybird female lays an optimum number of eggs in an aphid colony. Since an aphid colony is a finite and temporary food source, the time of its existence is just enough for the larvae of ladybird to complete their development but not reproduce in that colony (Figure 4)[16]. This implies

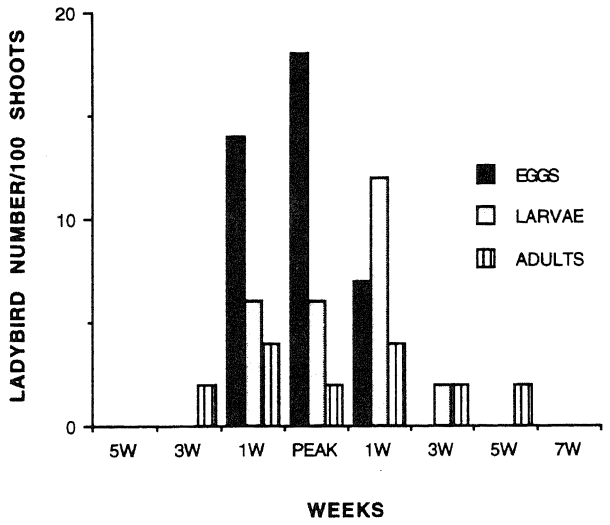

Figure 1. Distribution of ladybird eggs, larvae and adults of *Coccinella transversalis* in bean fields in time relative to peak abundance of aphid *Aphis craccivora*.

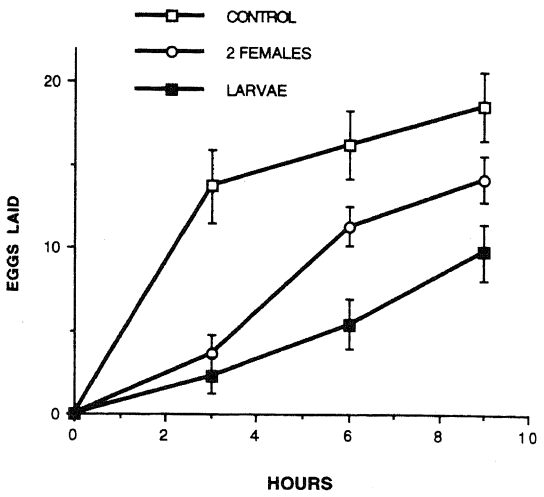

Figure 3. Average number of eggs laid by the females of ladybird *Adalia bipunctata* during 3, 6 and 9 h in 5 cm Petri dishes, in which they were kept singly, with another female or with three fourth-instar larvae (30 replicates for each treatment) (after ref. 14).

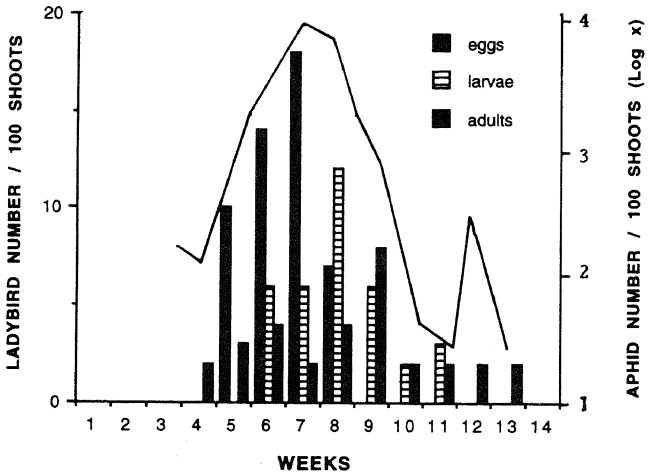

Figure 2. Number of aphid *A. craccivora* (—) and ladybird *C. transversalis* (histogram)/100 shoots recorded in bean field.

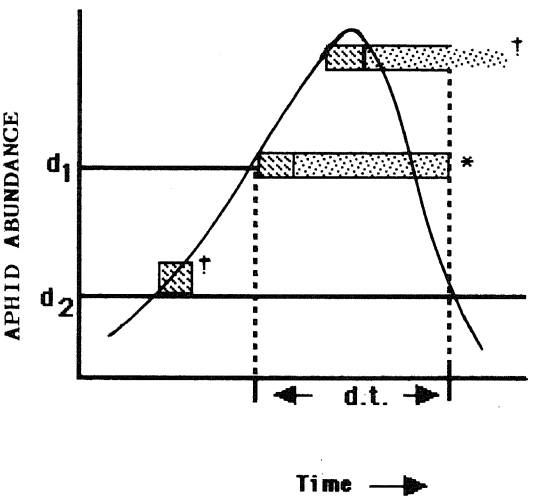

Figure 4. Reproductive behaviour of ladybirds: the period during which egg laying is compatible with the requirements for the survival of larvae. ▨ = egg laying, ⊞ = larval development (open means that larvae cannot complete their growth; †unsuccessful; *successful reproductive effort; d_1 and d_2 = threshold densities for the survival of first- and fourth-instar larvae, respectively; d.t. = developmental time) (after ref. 16).

that the optimum number of eggs laid by an adult ladybird corresponds to the maximum offspring biomass which can be supported by aphid biomass. Thus the reaction of ovipositing females to the presence of conspecific larvae in an aphid colony seems to be adaptive because it allows females (i) to choose young aphid colonies – the presence of larvae indicates that the aphid colony has been present for some time, and (ii) to avoid situations where competition for food could threaten the development of their offspring. Under these circumstances adult ladybirds are likely to leave an aphid aggregate and begin search for a new colony soon after a certain number of eggs are laid. Further studies on these aspects are currently being pursued by many investigators.

Cannibalism

An aphid colony is likely to be frequented by a succession of female ladybirds. As a result, larvae of different ages could forage on the same colony. Ladybirds which arrive late at an aphid colony are faced with optimization problem, i.e. the maximization of offspring production. Increase in predator density will bring about decrease in the number of prey available to each predator of

habitat (Hollying type II response)[17]. As a result, there will be a lower rate of increase in predators and a higher rate of cannibalism. Laboratory experiments reveal that egg and larval cannibalism are inversely related to aphid abundance (Figure 5). Conspecific eggs are more likely to be encountered and eaten than larvae because the former is immobile and laid in a cluster[18]. Field observations also suggest a density-dependent egg cannibalism in ladybirds[19]. However, ladybirds have developed effective mechanisms to avoid the risk of cannibalism: (i) the female ladybird does not oviposit in or immediately around an aphid colony because the adults and larvae aggregate there[20,21]; (ii) female ladybirds synchronize oviposition with the early development of aphid colonies, thus refraining from laying of eggs in the presence of larvae or even other females; and (iii) adult females are reluctant to eat their own eggs (Figure 6), and second-instar larvae have been seen to avoid eating sibling eggs[22]. This may be adaptive as it would reduce the chance of females eating their own eggs, whereas males are less likely to come across eggs they have sired. Non-sibling cannibalism, however, would still occur[21], and in a situation of prey scarcity this could be an effective means by which adults could fuel their reproductive efforts and eliminate potential competitors. This mechanism can ensure future availability of food for themselves and their offspring.

Predation

Ladybirds like *Adalia bipunctata* (L.), *A. decempunctata* (L.), *Coccinella septempunctata* L. and *C. undecimpunctata* L. commonly coexist in the same habitat[1]. In their coexistence their eggs and larvae are likely to occur in the same aphid colony[10]. Laboratory experiments indicate that the different species of ladybirds interact with one another, leading to predation of some of them (Figure 7)[18].

Available results suggest that interspecific predations are asymmetrical. Starving larvae and adults of *A.*

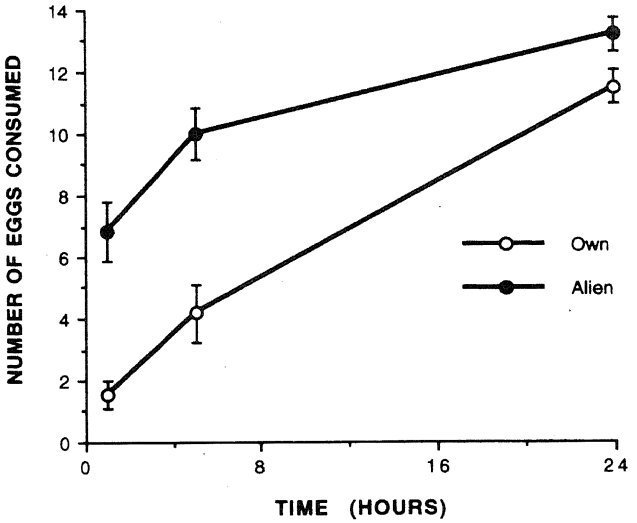

Figure 6. The mean number (± SE) of their own and alien eggs eaten by female *Adalia bipunctata* after 1, 5 and 24 h (after ref. 22).

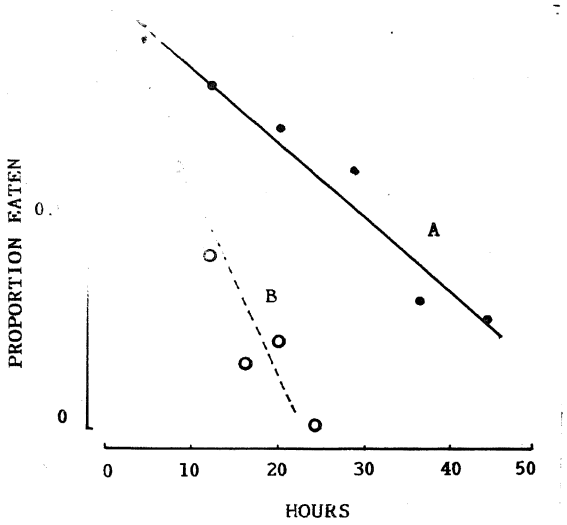

Figure 5. The proportion of the clutches of eggs (A, ●) and third-instar larvae (B, O) of *Adalia bipunctata* eaten by its fourth-instar larvae in relation to aphid density after 1, 5 and 24 h (eggs: $r^2 = 0.95$; $y = 1.007 - 0.0017x$; larvae: $r^2 = 0.91$, $y = 1.003 - 0.044x$; means of 20 observations) (after ref 18).

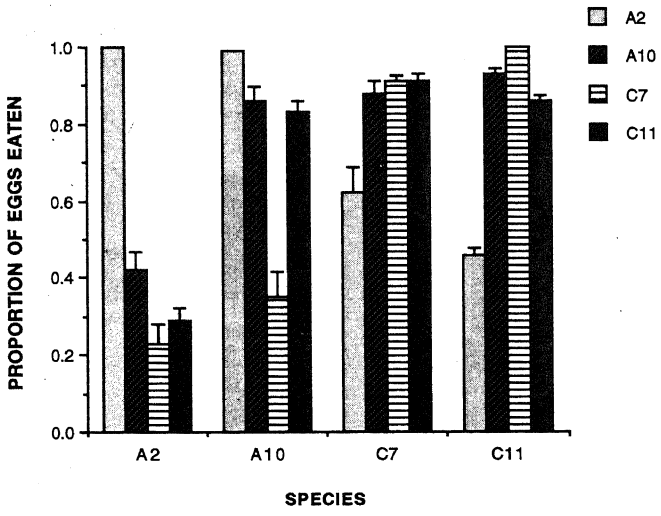

Figure 7. The proportion of eggs of their own and three other species eaten by larvae of four species of ladybirds (the four species are: *Adalia bipunctata* = A2, *A. decempunctata* = A10, *Coccinella septempunctata* = C7 and *C. undecimpunctata* = C11; 2- or 3-day-old fourth-instar larvae of the four species starved for 24 h prior to experiment; larvae were offered equal weight of eggs of the four species; *n* varies between 20 and 30) (after ref. 18).

bipunctata and *C. septempunctata* ate significantly fewer eggs of their own species when painted with a water extract of the eggs of other species. Thus, the eggs of both these species are protected to some extent from predation. The protective chemical used in this case was water-soluble (Figure 8)[18].

The results of further experiments have confirmed[19] that eating of the eggs of other species is not without risk, and that smaller species is better defended than larger species. An interesting study on the interaction between *A. bipunctata* (smaller species) and *C. septempunctata* (larger species) provides a good example. Larvae of the latter species fed on *A. bipunctata* eggs showed a significant increase in mortality than the larvae of former species fed on *C. septempunctata* eggs. The available information on interspecific predation is limited to a few of a large number of known ladybird species[1,23]. More results in future studies on a number of other species would strengthen the current thinking on interspecific predation and its possible impact on the reproductive behaviour of ladybird beetles.

That ladybirds use bitter-tasting alkaloids as a defence against predation by ants and birds[24–28] shows the chemical defence ability of the ladybird eggs. It would appear from the results that defence is based on odour rather than on colour. Recent studies suggest that clustered eggs of either *Coccinella transversalis* (Fabricius) or *Menochilus sexmaculatus* (Fabricius) are significantly less likely to be eaten by the larvae and adults of the rival species than the eggs offered singly (Agarwala, Bhattacharya and Bardhan Roy, in preparation). However, clustering of eggs does not prove to be a deterrant in cannibalism. In this context it is interesting to note that

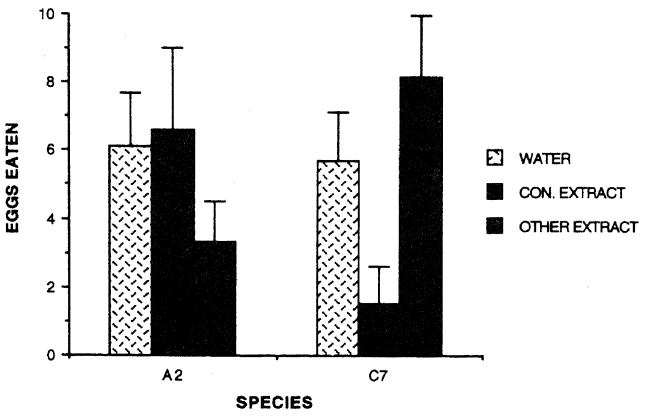

Figure 8. The effect on egg cannibalism in *Adalia bipunctata* and *Coccinella septempunctata* of painting eggs with water extract of conspecific eggs (concentrated extract) and a water extract of other species eggs (other extract) (1 mg of egg crushed in 0.15 ml of distilled water, centrifuged for 2 min and 0.05 ml of the supernatant painted on a batch of 10 eggs with a micropipette; eggs left dry for 2 h; 10 eggs offered to a starving fourth-instar larvae; experiments last 24 h; $n = 20$) (after refs 18 and 22).

alkaloids are present in the eggs, larvae, pupae and adults of ladybirds. The effectiveness of alkaloids in deterring ants is concentration-dependent[25]. Thus, clustering of eggs in ladybirds appears to be an anti-predatory device and, therefore, is another instance of adaptation for self-preservation. It would be useful to examine and define the chemical defence in ladybirds in future studies.

Conclusions

Aphid populations undergo seasonal changes in abundance. This ensures a strong selection pressure in ladybird beetles, who can successfully synchronize their development and reproduction with the phenology of aphid populations. As a result, ladybird species are able to maintain an optimum number of eggs and larvae in each aphid colony.

As aphid colony is a temporary habitat, a female ladybird chooses a young aphid colony for oviposition so that the resulting larvae could complete development. This behaviour of female ladybirds takes care of the new-born larvae, whose survival is dependent on an abundance of young aphids[29]. However, the number of eggs laid by a female has a finite relationship with prey abundance (reproductive numerical response) because (i) a satiated female is less active and, therefore, does not oviposit, and (ii) early hatching of larvae in aphid colony serves as a deterrant signal to the egg laying of females. Consequently, an optimal oviposition by a female ladybird is obvious in the early phase of aphid population development[6,14]. Such a reproductive strategy ensures that ladybird biomass production is proportional to the aphid biomass likely to be available in an aphid colony.

A lower reproductive response, thus, serves to maximize the fitness of ladybirds in terms of successful development of eggs that are laid in an aphid colony. However, a ladybird population has inherent dangers in its ecology: their positive prey-taxis in foraging and the likelihood of sharing of an aphid colony by populations of other ladybird species with a similar phenology pose considerable challenge to eggs and larvae from cannibalism and predation. Spatial distribution of ladybirds ensures that adults keep arriving at a patch of aphid colonies, resulting in predator pressure, both intraspecific and interspecific, on eggs and larvae. The pressure of intraspecific predation or cannibalism is avoided (i) in part by lower numerical response, which ensures that the optimal number of ladybird eggs laid in a particular colony should be lower, thereby not offering an opportunity of density-dependent cannibalism[19] and (ii) by the reluctance of a female to eat its own eggs, and also its inhibition in laying eggs in the presence of conspecific larvae. The ability of a ladybird to assess the quality of aphid colony diminishes the chances of egg and larval cannibalism.

Interspecific predation is subdued partly because ladybird eggs afford protection through chemical defence. Clustering of eggs in predatory ladybirds seems to be strongly adaptive. These devices not only result in increased fecundity in less time[30], so vital for its reproductive strategy, but also, more importantly, improve the chances of egg survival in two ways: (i) the defence acts as a distasteful deterrant to its predators[31,32], and (ii) some of the eggs in a cluster are inaccessible to parasites and predators[33].

The various accounts mentioned here suggest that ladybird beetles have evolved a combination of mechanisms that ensure their occurrence in an environment which suffers from limitations of temporary existence of prey and risks of predations. Some grounds of the reproductive strategy of ladybirds in response to cannibalism and predation have already been worked out but the hypothesis that clustered eggs are chemically defended against ladybird predators needs verification. Also there is a need to understand more precisely the prey–predator interactions in terms of factors which maximize the fitness of ladybird beetles in an uncertain habitat.

Radioactivity aspects of Indian coals

M. P. Rajan, M. A. R. Iyengar and T. V. Ramachandran*

Environmental Survey Laboratory, Health Physics Division, Bhabha Atomic Research Centre, Kalpakkam 603 102, India
*Environmental Assessment Division, Bhabha Atomic Research Centre, Bombay 400 085, India

This paper presents the results of a study of the radioactivity aspects of Indian coals. The measurements were carried out by gamma spectrometry and chemical methods for estimation of U-nat, Ra-226, Ra-228, K-40, Po-210 and Pb-210 in the samples. A brief description of sampling and measurement procedures are also given. Radiation dose estimates of the population from two typical thermal power stations at Neyveli and Ennore in Tamil Nadu have been attempted using the model developed by UNSCEAR and ORNL reports as guidelines, with suitable correction for local population density, plant load factor, fly-ash release, coal consumption per day, etc.

THE global energy needs have enormously increased with rapid strides in technology and to a large extent these have been met from fossil fuels. India has to depend largely on coal reserves for her energy needs to meet the present demand and possibly in future also. The annual requirement of coal is expected to go beyond 425 million tonnes by 2000 AD compared to current annual production of about 250 million tonnes. The total energy-generating capacity in the country is expected to be about 106 GW(e) by 2000 AD. Thermal power generation, as on 1994, is about 66% of the total generating capacity, i.e. about 65000 MW(e).

Combustion of coal in thermal power stations (TPSs) gives rise to gaseous and particulate pollution in the environment, such as SO_2, NO_x, particulate matter, etc., which have long-term effects on vegetation, fish, animal life, human beings and even on buildings, structures, etc. This has also resulted in the release of large quantities of CO_2 adding to its continuous build-up of its level in the environment. It has been estimated that a 1000 MW(e) coal-fired power station consumes about 3 million tonnes of coal per year, producing 7 million tonnes of CO_2, 0.12 million tonnes of SO_2, 0.02 million tonnes of NO_x and 0.75 million tonnes of ash[1]. The present coal consumption in TPS in the country results in adding an estimated 12.2 million tonnes of fly-ash into the environment every year, of which nearly a third goes into the air and the rest is dumped on land or discharged in waterbodies.

In India, most of the coal available is of bituminous type. The quality of Indian coal is poor with 5–50% ash, 1–30% moisture, 79–82% carbon, 3.5–6.0% hydrogen, 0.8–2.4% nitrogen, 1.3–10% oxygen, 13–50% volatile matter, 0.2–2.0% sulphur and 0.01–0.4% phosphorus. Besides, coal also contains radioactivity due to primordial uranium and thorium series nuclides and K-40; during its combustion these natural radionuclides are readily released which disperse over a large area in the vicinity of TPSs[2,3]. Unlike most of the nuclear and hydroelectric power stations, coal-fired power stations in India are generally located in areas which are thickly populated and hence the environmental impact experienced by the neighbourhood population may be of significance. Due to the high ash content of coal and relatively poor fly-ash control measures, particulate pollution as well as natural radioactivity deposition due to TPSs in India are higher than in some of the western countries. However, recently built TPSs in India have installed modern pollution control technologies which mitigate the pollution levels in the environment to a considerable degree.

In the light of the possible radiological significance in the environment, studies have been carried out by several investigators in different parts of the world to assess the nature and quantity of radioactivity releases from thermal power stations using coal as fuel. Some of these studies have shown that the radiation hazard in the environment of the coal-fired power stations is comparable and sometimes even higher than that of nuclear power stations[4–6]. There is thus considerable interest in investigating the radioactivity aspects of coal and fly-ash in Indian TPSs and their significance in terms of environmental impact and public radiation exposures. This paper presents the results of a study carried out to assess the radiological aspects of certain selected TPS units in the country using both coal and lignite.

Materials and methods

Coal samples for the study were obtained from West Bengal, Chanda (Maharashtra), Singareni (Andhra Pradesh) and Talcher (Orissa) coal fields. Lignite samples were collected from various locations of the Neyveli Lignite Corporation in South Arcot District of Tamil Nadu. The fly-ash and slag (bottom ash) samples were obtained from Singareni, Ennore and Neyveli power stations. Coal, fly-ash and slag samples thus obtained were thoroughly mixed, dried and ground to a fine powder and nearly 200 g each of the sample was filled and topped up in an air-tight plastic container of 6.5 × 7.5 cm size and stored for nearly a month before

counting to ensure that nat. U and Th attain equilibrium with their respective daughters[2].

Standard sources of uranium and thorium have also been prepared in the same geometry by mixing known quantities of uranium ore and thorium nitrate salt with an inactive matrix having density close to those of the samples. For preparing K-40 standard, potassium chloride of Analar grade was used directly. Source strengths were selected in a way that would yield a low statistical error in channel counts for nearly one-hour counting. Sodium oxalate was used as a dummy matrix because it has low radioactivity content, is nonhygroscopic and has density close to the sample matrix. The overall errors due to sampling and source preparation were estimated to be ± 15% (ref. 2). The thorium nitrate and the uranium ore used for the source preparation were more than 15 years old and hence it was ensured that radium and thorium-228 had attained radioactive equilibrium with their daughters.

The selection of the 12.5 × 10.0 cm NaI (Tl) detector of Harshaw make for the present work was made keeping in view the low specific activity of the samples to be counted and the maximum energy of interest[7]. The detector offers the best compromise if the energy of interest is up to 3 MeV. Similarly, the selection of the multichannel analyser for the analysis is also based on the criteria outlined by Schonfeld[8]. The choice of the internal dimensions of the lead shield and of lining it with cadmium and copper were also made to reduce the low-energy scattered background.

Some of these samples were also analysed by radiochemical methods to determine concentrations of radionuclides like U-nat, Ra-226, Ra-228, Po-210 and Pb-210. Details regarding the radioanalytical procedures used in the study are described elsewhere[9,10].

Results

From the gamma spectrometric analysis of the samples, it was observed that the coal and its fly-ash samples contained radionuclides from both uranium and thorium series, while it was interesting to note that the lignite and fly-ash samples from Neyveli showed predominantly radionuclides from uranium series.

Tables 1 and 2 give the results of the radiochemical analysis of the samples investigated. From Table 1 it can be seen that the coal samples from different regions showed more or less similar activity content, whereas the lignite samples showed a considerable variation in the activity levels. From Table 2, it can be seen that the lignite fly-ash contains higher amount of U-nat, Ra-226, Po-210 and Pb-210 compared to the respective concentrations of these nuclides in coal fly-ash.

Among the samples investigated, the samples from Neyveli region showed evidence of higher concentration of uranium. The carbonaceous clay, which is present as a layer above the lignite seam, contains small amounts of U_3O_8 and is the main constituent which may be responsible for the observed higher concentration of uranium in the lignite samples[2,3]. Table 3 gives the

observed levels of radionuclides in lignite from different layers as seen at the mine. The increase in the activity content of lignite fly-ash can be clearly traced to the mixing of the relatively higher activity of carbonaceous clay with lignite during the mining process and pulverization, prior to combustion in the power station.

Dose assessment

In view of the range of activities and respective levels and the wide dispersion potential of radioactivity from coal-fired TPSs, it is of interest to calculate the doses received, if any, by the public inhabiting the neighbouring environment. In our earlier publications[11,12], the radiation dose commitments to the population living within 80 km radius of thermal power stations were calculated following the 1980 UNSCEAR report. This was calculated on the basis of an assumed plant load factor of 50%, average coal consumption of 15 tons per day per MW(e) and 30% ash content of coal. A good deal of work has been done in the past few years by several investigators on assessing the doses and dose commitments from energy production in coal-fired and nuclear power plants. A review of the methods used for such calculations by De Santis[5] has been taken into account and the method described by McBride *et al.*[4] has been adopted. The method described in this report gives a clear procedure for dose assessment from a model 1000 MW(e) coal-fired and nuclear power plants.

In the present calculations the actual average plant load factor during the period of sampling, the coal consumption, and the ash content of the coal used in a particular power plant, have been used[13,14] (Table 4). These calculations were also modified in the light of ICRP recommendations of 1977, i.e. change of quality factor for alpha particles from 10 to 20 and the concept of collective effective dose equivalent commitments. The Ennore TPS near Madras is equipped with electrostatic precipitators, for which an average fly-ash control of 97% was assumed. The Neyveli TPS was equipped with mechanical or cyclone collector at the time of sample collection and a fly-ash control of 82% was assumed for this plant. These factors have been applied in deriving the dose estimates.

McBride *et al.*[4] assumed that all the daughters of the uranium and thorium series were in equilibrium and had calculated the radiation doses in the population living within 88.5 km of the plant under normal climatic conditions using the AIRDOSE computer code for the atmospheric dispersion calculations. The annual precipitation assumed in these calculations is about 900 mm. The TPSs under the present study fall in the range of 600–1000 mm annual rainfall. Hence, the data of McBride *et al.*[4] were used for calculation of dose with appropriate corrections for population density[15,16], installed capacity, coal consumption and ash content, fly-ash control factor, average load factor for the sampling period and lastly the activity release ratio of the actual activity released in Indian TPSs to that of the model TPS.

Using the above correction factors and assumption

Table 3. Radioactivity content in lignite samples of Neyveli

*PLF – plant load factor.

for release considered by McBride *et al.*[4], it was found that, of the total dose received, uranium daughters contribute 75, 77, 61 and 76% of the total dose to the whole body, bone, lungs and thyroid, respectively. The corresponding figures for Ra-228, Th-228 of thorium series were 22, 18, 33 and 22% of the total dose. The contribution to the doses and dose commitments from the airborne releases of U and Th daughter products due to inhalation and direct gamma irradiation from surface deposition are 6.5, 17, 38 and 6.4% to the whole body, bone, lungs and the thyroid, respectively, the remainder arising through ingestion pathways. The doses and dose commitments from the airborne releases from thermal power stations were calculated only for the whole body, bone, lungs and thyroid as these are the doses usually considered in the context of nuclear power plants. They are also used elsewhere[12] for comparison between these two energy production technologies.

Dose estimates from K-40 have not been included because the levels of K-40 in man are homeostatically controlled. The lung is the critical organ for Rn-222 but the Rn-222 contribution to the total lung dose is only about 1 part in a million[4]. Hence, doses due to radon and its daughters are neglected in the present dose assessment and the dose assessment is done only for Th-230, Ra-226, Po-210 and Pb-210 from the U series and Th-232, Ra-228, Th-228 from the Th series.

The resulting equations based on the above considerations and assumptions for assessment of doses and dose commitments (in man-Sv. Y^{-1}) are as follows:

$$\text{Wholebody and thyroid} = 9.5 \times 10^{-8} P\ (mx + ny) \cdot d,$$
$$\text{Bone} = 2.7 \times 10^{-6} P\ (mx + ny) \cdot d,$$
$$\text{Lungs} = 7.7 \times 10^{-7} P\ (mx + ny) \cdot d,$$

where x and y refer to the radionuclides concentrations of Ra-226 and Th-228 in Bq/kg of fly-ash, d is the population density per km^2 in an 88.5 km radius environment and P is the total installed capacity in MW(e). The constants m and n are defined as follows:

m = (annual ash released from the stack in kg for 1000 MW(e)) × (dose conversion factor from U series) × (296 MBq of Ra-226)$^{-1}$,

n = (annual ash released from the stack in kg for 1000 MW(e)) × (dose conversion factor from Th series) × (185 MBq of Th-228)$^{-1}$

The values of dose conversion factors for the uranium and thorium series for different body organs have been reported earlier[17]. Plant load factors are incorporated in the computation of m and n.

The conversion of the collective dose equivalent commitments into collective effective dose equivalent commitments allows a better evaluation of the hazard of radionuclides exposures for risk estimates. Hence, all the doses estimated in the foregoing to different body organs have been converted to collective effective dose equivalent commitments and the calculated results of the dose assessments are given in detail in Table 4 for the TPSs studied.

Discussion

Among the samples analysed, the lignite and its fly-ash samples from Neyveli were found to contain more radioactivity due to uranium series radionuclides, compared to coal and its fly-ash samples from other parts of India. This gives rise to higher collective doses at Neyveli as is clear from Table 4.

The doses reported in the paper are due to the inhalation of radionuclides contained in the fly-ash released through the stack. However, for ingestion route, an investigation of environmental samples such as water, air, vegetation, fish, etc., from Ennore and Neyveli TPSs, revealed that the activities due to Ra-226, Ra-228, U-nat, etc., in these samples were in the same range as that of the samples collected from a control area free from any type of industrial pollution. Therefore, it can be concluded that the collective dose is coming essentially from the inhalation route and the dose from the ingestion route is negligible.

ACKNOWLEDGEMENTS. We thank all the TPS authorities at Ennore, Neyveli, Singareni, etc., for providing us with coal and fly-ash samples and rendering help in collecting various types of samples from the station and their environment. We also thank Shri S. Krishnamony, Head, Health Physics Division; Dr K.S.V. Nambi, Head, Environmental Assessment Division; and Shri M. Sundaram, Head, PPSS, Health Physics Division, for their active interest in the study. We are also grateful to Dr N.S. Krishna Prasad, formerly of Uranium Extraction Division, BARC, for his valuable guidance and useful discussions during the course of the work.

Composition and enzyme activities in *Aspergillus flavipes* grown on crude petroleum oil and glucose

J. Savitha* and C. V. Subramanian**

Centre for Advanced Study in Botany, University of Madras, Guindy Campus, Madras 600 025, India
*Present address: Department of Microbiology, Bangalore University, Bangalore 560 056, India
**'Anjaneya', 62, Dr Ramaswamy Salai, West K. K. Nagar, Madras 600 078, India

Aspects of the growth, cellular composition and enzymology of *Aspergillus flavipes* grown on a medium with crude oil or glucose as the sole source of carbon are reported. When grown on crude oil, the total lipid content of *A. flavipes* was considerably greater than on glucose medium. A large number of fatty acids, particularly saturated fatty acids, were observed when grown on crude oil and more lipid was excreted into the growth medium. The total mycelial carbohydrate and glycogen contents were considerably less in crude oil medium, whereas the mycelial protein content was similar in both media. The activity of some enzymes like NAD^+-alcohol dehydrogenase, $NADP^+$-aldehyde dehydrogenase, iso-citrate lyase and catalase was greater when crude oil was the carbon source. Conversely, the activity of succinate dehydrogenase was greater after growth on glucose medium.

THE subject of degradation and utilization of hydrocarbons by fungi has received considerable attention[1–3] but much more remains to be done[4]. A strain of *Aspergillus flavipes* isolated from the effluents of the Madras Oil Refineries that can degrade hydrocarbons in crude petroleum oil was reported earlier[5]. Work on utilization of hydrocarbons has mainly been carried out on a few selected bacteria, and some fungi, notably species of *Candida* and the kerosene fungus *Cladosporium resinae*[6–8]. Much of this work has used specific hydrocarbons such as alkanes of known chain length. In the present study, however, we have examined the potential of *A. flavipes* isolated from the effluents of the Madras Oil Refineries to degrade crude petroleum oil, which often forms around 2% (v/v) or more of the effluent from the refinery. The emphasis in the study has been on the utilization of crude oil *per se* rather than particular components of the oil.

We have examined the amount of total protein, total carbohydrate, glycogen, total lipids, total sterol, fatty acids (saturated and unsaturated) in *A. flavipes* grown with either crude oil or glucose as the sole source of carbon. As a preliminary to understanding the physiology of utilization of crude oil, some data are given on the enzymology of crude oil and glucose utilization.

Materials and methods

Organism. A single spore isolate of *A. flavipes* isolated from the effluents of the Madras Oil Refineries Ltd., Manali, Madras, was used throughout the study. It was maintained on potato dextrose agar (PDA).

Culture techniques. Standard microbiological techniques were used in the preparation of media, sterilization etc.[9]. The fungus was grown in a mineral salts solution of Bushnell and Haas[10] supplemented with 0.1% (w/v) yeast extract, adjusted to pH 6.0. Glucose (10 g l^{-1}) was added to mineral salts solution before the autoclaving. Crude oil was filter-sterilized (pore size, 0.41 μm) and added to sterile mineral salts solution to give 10 g l^{-1}. Flasks (250 ml) containing 100 ml medium were inocu-

lated with 1 ml of a spore suspension (1×10^6 spores ml^{-1}) and incubated at 28 ± 2°C under static conditions. Spores were harvested in sterile distilled water from PDA plates overlaid with cellophane.

Determination of fungal growth. The mycelial mat was harvested by filtering through a predried and weighed Whatman no. 1 filter paper. The mat was washed three times with chloroform and then with distilled water, and dried at 100°C for 25 h; the dry weight of the mycelium was then determined.

Protein estimation. Total protein was estimated by the method of Lowry *et al.*[11] using bovine serum albumin as standard.

Determination of total sugar and glycogen. Total sugar and glycogen were estimated according to Roe[12] and Morales *et al.*[13], respectively.

Estimation of total lipid. Total lipid was extracted from 10 g fresh weight of mycelium as described by Folch *et al.*[14] and estimated gravimetrically.

Separation and estimation of neutral, glycolipid and phospholipid by column chromatography. The total lipid was fractionated into its constituent lipid classes by silicic acid column chromatography[15]. Neutral lipid was eluted with eight column volumes of chloroform, glycolipid with one column volume of 99% (v/v) acetone and phospholipid with eight column volumes of methanol. Solvents were evaporated and the lipid fractions were estimated gravimetrically. The percentage of lipid fractions in total lipid was then calculated.

Extraction of extracellular lipid. Extracellular lipid was extracted from the culture medium by the method of Siporin and Cooney[16]. The mycelial mat was removed from the medium by filtering the culture through two layers of Whatman no. 1 filter paper. In cultures grown on crude oil a thin layer of residual oil was present on the surface of the medium. This layer was removed by shaking 100 ml of medium with 10 ml petroleum ether and removing the upper solvent phase. The aqueous phase was adjusted to pH 2 with HCl and extracted three times with two volumes of chloroform : methanol (2 : 1 v/v).

Extraction of total extracellular lipid by thin layer chromatography (tlc). The total extracellular lipid was separated into free fatty acid and phospholipid fractions by tlc using chloroform : acetone : methanol : acetic acid : water (8 : 1 : 5 : 25 : 0.25 v/v) as solvent[16]. Lipids were visualized by iodine vapour. Spots corresponding to standard free fatty acid and phospholipid were eluted with hexane, dried in nitrogen atmosphere and stored at –4°C. The amount of total free fatty acid[17] and phospholipid[18] was estimated spectrophotometrically.

Fatty acid analysis. Fatty acids were converted to their methyl esters using borontrifluoride : methanol[19] and separated by gas chromatography using a polar column (10% w/w, diethylene glycol succinate on chromosorb/Aw) operated at 190°C. The relative proportions of the different fatty acids were calculated by manual measurement.

Measurement of enzyme activity. Activities of the NAD^+-alcohol dehydrogenase, $NADP^+$-alcohol dehydrogenase and $NAD(P)^+$-aldehyde dehydrogenase were measured spectrophotometrically at 340 nm following the procedures of Bonnichsen[20], Demoss[21] and Seegmiller[22], respectively. Succinate dehydrogenase was assayed[23] at 428 nm. Isocitrate lyase was measured[24] at 324 nm. Catalase was measured as described by Beers and Sizer[25].

Statistical analysis. All experiments were carried out in duplicate and each experiment repeated three times, except the cellular and extracellular fatty acid experiments, which were repeated twice with no replicates. Data obtained were analysed statistically[26]. Student's *t* test was used to calculate the degree of significance between glucose and crude oil.

Results

Growth and composition (cellular) of A. flavipes. When grown in static culture on glucose the stationary phase was reached after 6 days, but on crude oil the growth was not complete until the twelfth day. To determine the cellular composition, the fungus was harvested at four sample times during its growth period (Figure 1).

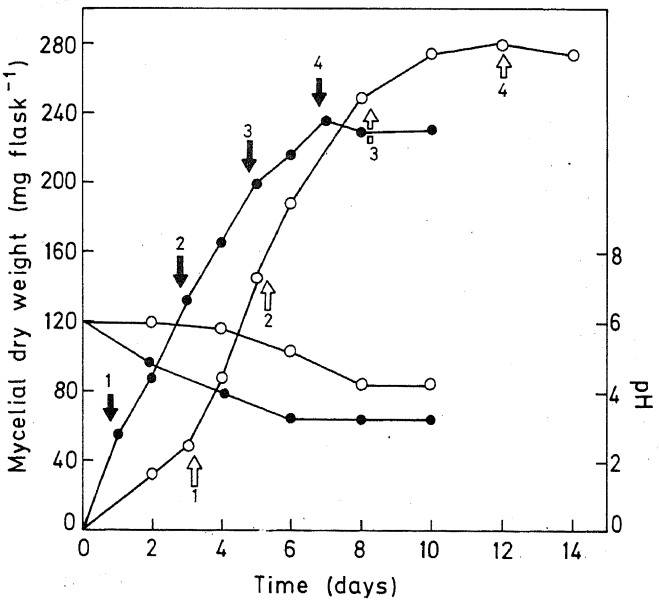

Figure 1. Growth of *A. flavipes* grown on medium with glucose and crude petroleum oil as the sole source of carbon: ● glucose; O crude oil. Arrows indicate sample times. The experiment was carried out in triplicate.

Variations in cellular composition of *A. flavipes* were observed after growth on crude oil or glucose media. Total carbohydrate and glycogen contents were approximately twofold greater in mycelia grown on glucose although protein content was not significantly different between the two media (Table 1). Considerable increases in total lipid and sterol contents were observed for the crude-oil-grown cultures (Table 1). In cultures grown on crude oil, neutral lipid was the major fraction followed by glycolipid, whereas in glucose-grown cultures glycolipid was the major fraction, followed by neutral lipid. However, on both media phospholipid was the minor fraction (Table 2). The lipid of crude-oil-grown cultures contained a variety of fatty acids compared to that of glucose-grown cultures. Also, the crude-oil-grown cultures showed an increase in the percentage of total unsaturated fatty acid with time (Table 3).

Extracellular lipid. In the presence of crude oil

A. flavipes excreted three to four times more lipid into the growth medium than when grown on glucose (Table 4 *a*). When the total lipid was fractionated by column chromatography, it failed to separate into definite fractions such as neutral lipid or glycolipid. However, after tlc free fatty acids were found to be the major lipid fraction. The free fatty acid content was nearly double in the medium with crude oil than in the medium with glucose (Table 4 *b*). The level of phospholipid was significantly higher in glucose medium than in crude oil medium. Methyl esters prepared from free fatty acid fractions of lipid extracted from medium with glucose or crude oil gave both saturated and unsaturated even-chain fatty acids; no odd-chain fatty acids were detected (Table 5).

Enzymology. In cultures grown on crude oil, the activities of NAD^+-alcohol dehydrogenase and $NADP^+$-aldehyde dehydrogenase were nearly three and two times more (respectively) than that of glucose-grown cultures, whereas $NADP^+$-alcohol dehydrogenase and NAD^+-aldehyde dehydrogenase did not show any significant difference in their activity on the two media (Table 6). Succinate dehydrogenase activity was considerably lower in the crude-oil-grown cultures, whereas isocitrate lyase and catalase activities were considerably higher in the crude-oil-grown cultures (Table 6).

Discussion

It is interesting to note that the lipid content of *A. flavipes* was considerably greater (sixfold) when grown on crude oil as the sole carbon source compared to glucose. *A. flavipes* accumulates lipid more efficiently than either *Candida lipolytica*[29] or *Cladosporium resinae*[30] where two to threefold increases in lipid content of cultures grown on *n*-hexadecane have been reported. Growth of *A. flavipes* on crude oil resulted in the occurrence of a greater number of fatty acids, particularly saturated fatty acids (Table 3). The fatty acids are oxidation products of *n*-alkanes in the crude oil which are then incorporated into the cellular lipids. The content of saturated fatty acids decreases progressively in cultures grown on crude oil. This may be due to some of the short-chain saturated fatty acids being converted into long-chain fatty acids, especially unsaturated fatty acids, which can be used to produce storage lipids[4].

The function of extracellular free fatty acids, which increase during growth on crude oil (Table 4 *b*), is possibly to emulsify the hydrocarbons to facilitate their uptake by the fungus[26].

Induction of NAD^+-alcohol dehydrogenase and $NADP^+$-aldehyde dehydrogenase in crude-oil-grown *A. flavipes* suggests their involvement in the oxidation of alkanes in crude oil. Iso-citrate lyase is the key enzyme of the glyoxylate cycle which plays an important role in the biosynthesis of cellular components such as malate or succinate. Activity of isocitrate lyase was significantly greater when *A. flavipes* was grown on crude oil. Conversely, the activity of succinate dehydrogenase was greater in glucose medium (Table 6). From these results, it is possible to infer that the intermediates of tricarboxylic acid cycle are synthesized from acetyl COA derived from the degradation of fatty acids via glyoxylate cycle[29]. Peroxisomes are thought to contain several enzymes involved in fatty acid metabolism such as catalase, iso-citrate lyase, etc. The increase in these enzymes observed in crude-oil-grown *A. flavipes* suggests an increase in the number of peroxisomes although we have no data to support this supposition. However, this finding is in agreement with those of other workers, who report a similar increase in catalase and iso-citrate lyase activities and increase in the number of peroxisome for *C. resinae*[4] and *Candida tropicalis*[30].

The work described here is the first report on the composition and enzyme activities in a fungus grown on crude petroleum oil and glucose. The most significant aspect of the study lies in the fact that an attempt has been made here to elucidate the metabolism and enzymology of *A. flavipes* when grown on crude petroleum oil, which is a natural component of industrial wastes and effluents.

Liv.52 pretreatment inhibits the radiation-induced lipid peroxidation in mouse liver

N. G. Ganapathi and Ganesh Chandra Jagetia

Department of Radiobiology, Kasturba Medical College, Manipal 576 119, India

The effect of Liv.52 on mice liver mitochondrial lipid peroxidation was measured in terms of malanoldehyde (MDA) generation after exposure to 3.0 Gy of gamma radiation at ¼, ½, 1, 2, 4, 8, 24 and 48 h post-irradiation. The lipid peroxidation level increased significantly from ¼ h and reached a peak level at 4 h post-irradiation, and gradually declined thereafter in the irradiated control group. Liv.52 treatment before irradiation inhibited the formation of lipid peroxidation significantly at all the post-irradiation sampling time.

LIPID peroxidation is initiated by reactive oxygen species (ROS) in aerobic living organisms. Superoxide radical (O_2^-) and hydrogen peroxide (H_2O_2) are generated during metabolism, oxidation and irradiation, and they in turn are converted to hydroxyl free radical ($OH^\cdot$). The hydrogen atom in unsaturated fatty acids can be abstracted by the OH radical following the formation of lipid alkyl radical ($R^\cdot$), which initiates the chain reaction of lipid peroxidation in an aerobic condition.

Lipid peroxidation alters the fluidity of biological membranes and then causes cell degradation, affecting the biological defence mechanism. The product of lipid peroxidation, such as malanoldehyde (MDA), damages the enzyme system and DNA[1]. Lipid peroxidation has been used as an end point to study the action of oxidizing and free-radical-producing agents as well as to investigate the effects of intracellular radical scavengers (i.e. as an overall measurement of oxidative injury to the cellular membranes). Lipid peroxidation is considered to be an important effect of ionizing radiation on biological membranes[2–4].

Radiation-induced lipid peroxidation has been reported to be caused by superoxide radicals[5]. However, later studies confirmed that the hydroxyl radical is the most active species involved in radiation-induced lipid peroxidation[3,6–8].

Natural products such as herbal medicines have only recently begun to receive some attention as possible modifiers of the radiation response. Liv.52, a non-toxic herbal preparation composed of *Capparis spinosa*, *Cichorium intybus*, *Solanum nigrum*, *Cassia occidentalis*, *Terminalia arjuna*, *Achillea millefolium* and *Tamarix gallica*, has been reported to be clinically effective in treating hepatotoxicity and a wide range of hepatic disorders[9–11]. The radioprotective potential of Liv.52 was demonstrated for the first time in mice[12]. Recently, it has been reported that prior administration of Liv.52 protected mouse bone marrow against radiation-induced chromosome damage[13,14]. A significant decrease in lipid peroxidation, followed by an increase in the tocopherol level in Liv.52-fed groups, was observed[15]. Saxena and Garg[16] also reported that the feeding of Liv.52 to rats gave a marked protection against the increase in lipid peroxidation and phospholipid contents of microsomal fraction.

Therefore, it was desired to obtain an insight into the effect of Liv.52 on lipid peroxidation in mouse liver exposed to 3 Gy of ^{60}Co gamma radiation.

Six- to eight-week-old male Swiss albino mice weighing 25–30 g were selected from an inbred colony maintained under controlled conditions of temperature (23 ± 2°C), humidity (50 ± 5%) and light (10 and 14 h of light and dark, respectively). The animals were given sterile food prepared as per the standard formulation (wheat 70%, Bengal gram 20%, fish meal 5%, yeast powder 4%, sesame oil 0.75% and shark liver oil 0.25%) in the laboratory and water *ad libitum*. Throughout the experiment 5–6 animals were housed in a sterile polypropylene cage containing sterile paddy husk (procured locally) as bedding material. The irradiation was carried out using telecobalt therapy source (Gammatron, Siemens, Germany).

A batch of 10 immobilized animals (achieved by inserting cotton plugs in the restrainer) was kept prone in specially designed well-ventilated acrylic box during exposure. The irradiation was carried out at a dose rate of 0.88 Gy/min. The source-to-animal distance was 60–63 cm. The exposure area of 20 × 20 cm was also kept constant. The dosimetry calculation were done by Dr J. G. R. Solomon, Department of Radiotherapy and Oncology, K. M. C. Manipal.

As the Liv.52 powder is insoluble in water, a dose of 500 mg/kg body wt of Liv.52 powder was suspended in 10 ml of 5% dextrose solution containing gum acacia. 0.01 ml/g body wt of Liv.52 or 5% dextrose was administered orally once a day for 7 days using 22-gauge oral feeding needles (Popper & Sons Inc., New York, USA).

The animals were divided into two groups. One group of animals was fed with 5% dextrose solution and served as the control group, while the other group received 500 mg/kg body wt of Liv.52 powder in 5% dextrose solution. After 1 h of administration on day 7, the animals of both groups were exposed to 3 Gy of ^{60}Co gamma radiation. Subsequently, a few animals were also treated with 5% dextrose and Liv.52 but without irradiation, for the sake of comparison. Usually, five animals

Liv.52 is a commercial product marketed by The Himalaya Drug Co., Bangalore. Use of the trade name does not imply endorsement of the product.

were used for each time period for each group studied. A total of 90 animals were used for the whole experiment.

The animals from both groups were anaesthetized by administration of overdose of diethyl ether anaesthesia and were killed at ¼, ½, 1, 2, 4, 8, 24 and 48 h post-irradiation. The livers of the animals were perfused with isotonic saline and removed and weighed. A 10% liver homogenate was prepared in 0.2 M Tris–HCl buffer (pH 7.4) using Yamato LSG homogenizer LH-21 (Japan). The lipid peroxidation in liver was estimated by the method of Konings and Drijver[17]. Briefly, the homogenate was centrifuged at 50,000 × *g* (Sorvall, RC 5B, USA) for 10 min at 4°C and the pellet was discarded. The resultant supernatant was centrifuged again for 60 min at 4°C to obtain mitochondrial pellet. A homogeneous suspension of mitochondria was prepared in 0.2 M Tris–HCl buffer (pH 7.4). To this suspension 150 mM KCl, 0.3 mM ascorbic acid and 0.2 M Tris–HCl buffer (pH 7.4) were added, and it was incubated at 37°C for 1 h. After incubation, trichloroacetic acid was added followed by the addition of 0.67% TBA. The test tubes were kept in boiling water bath for 15 min. The tubes were removed from the water bath and allowed to cool. The tubes were centrifuged and the resultant supernatant was filtered through Whatman filter paper. The absorbance of the sample was read against the blank at A_{max} 532 nm in a UV–VIS recording spectrophotometer (Shimadzu UV–VIS 260, Japan). Mitochondrial protein concentration was determined by the method of Bradford[18]. The data were analysed statistically by Student's *t* test on an IBM/PC.

The lipid peroxidation was expressed in terms of nmol MDA/mg protein. Liv.52 treatment did not alter the level of lipid peroxidation (Table 1).

The exposure of animals to 3.0 Gy ^{60}Co gamma radiation resulted in a significant increase in lipid peroxidation at all the time periods studied compared to the sham-irradiated control. The activity of lipid peroxidation started increasing at ¼ h and reached a peak level by 4 h post-irradiation (Figure 1). This increase was approximately 1.88, 2.4, 2.0, 2.6 and 3 folds higher for ¼, ½, 1, 2, and 4 h post-exposure, respectively, compared to the sham-irradiated animals. An abrupt decline in the lipid peroxidation level was observed at 8 h, which was approximately half of the preceding sampling time. However, lipid peroxidation did not attain normal level even by 48 h post-irradiation (Table 1).

In the Liv.52 + irradiated group a significant increase in lipid peroxidation compared to sham-irradiated animals was observed only at ½ h post-irradiation. However, Liv.52 administration before irradiation inhibited lipid peroxidation significantly at all the time periods studied. It was 23.61, 21.64, 24.93, 43.99, 52.04, 26.81, 9.21 and 20.81% lower for ¼, ½, 2, 4, 8, 24 and 48 h post-irradiation, respectively, compared to the concurrent irradiated controls.

Lipid peroxidation induced by radiation is known to be due to the attack of free radicals on the fatty acid component of membrane lipids[7,19,20]. Mitochondrial membranes contain high percentage of polyunsaturated fatty acids and are, therefore, susceptible to free-radical attack[21]. Damage of mitochondrial structures and enhanced lipid peroxidation by ionizing radiation has been reported[22,23]. Lipid peroxidation also results in mitochondrial swelling and disintegration[24].

Irradiation of animals to 3.0 Gy of gamma radiation resulted in a significant increase in lipid peroxidation level at all the time intervals compared to the sham-irradiated group. The lipid peroxidation level started increasing at ¼ h and reached a peak level at 4 h after exposure. This increase was approximately 1.88, 2.4, 2, 2.6 and 3 folds higher for ¼, ½, 1, 2, and 4 h post-irradiation respectively, compared to the sham-irradiated group. The glutathione depletion was maximum at 15 and 45 min after exposure to 3.0 Gy of gamma radiation (unpublished data). These findings are in good agreement with the earlier findings, where maximum depletion of GSH at 15–30 min and the highest lipid peroxidation 4 h after 3.0 Gy of gamma radiation have been reported[25]. Similarly, a maximum depletion in GSH at 15–30 min and lipid peroxidation as well as liver necrosis at 2–4 h after administration of allyl alcohol in mice have been observed[26,27]. Lipid peroxidation has been suggested as one of the main causes of radiation-induced membrane damage[2,3]. The lipid peroxidation has been found to increase with increase in radiation dose in rat liver microsomes and in mice erythrocytes[28,29].

Table 1. Effect of Liv.52 on the radiation-induced lipid peroxidation in mouse liver

Time (min/h)	nmol MDA/mg protein (mean ± SEM)	
	3.0 Gy	Liv.52 + 3.0 Gy
¼	3.43 ± 0.22^a	2.62 ± 0.09^d
½	4.62 ± 0.20^a	3.62 ± 0.14^d
1	3.89 ± 0.13^a	2.92 ± 0.23^e
2	5.16 ± 0.10^a	2.89 ± 0.04^a
4	6.11 ± 0.23^a	2.93 ± 0.31^e
8	3.99 ± 0.10^a	2.92 ± 0.09^c
24	3.15 ± 0.06^b	2.86 ± 0.06^f
48	2.69 ± 0.09^d	2.13 ± 0.10^d

Normal control value = 1.95 ± 0.06.
Liv.52 control value = 2.20 ± 0.09.
Normal compared with irradiated group column 1 symbols on right side.
The difference between normal control and Liv.52 control was non-significant.
Liv.52 alone compared with Liv.52 + irradiated group column 2 symbols on left side.
Irradiated groups compared with Liv.52 + irradiated groups column 2 symbols on right side.
$^a p < 0.0001$, $^b p < 0.0002$, $^c p < 0.0003$, $^d p < 0.001$, $^e p < 0.002$, $^f p < 0.01$.

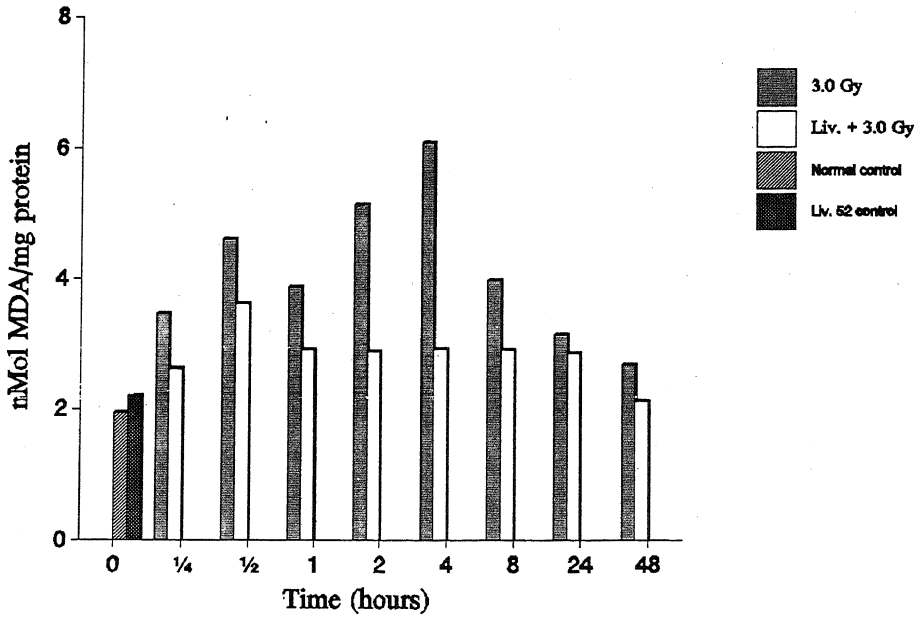

Figure 1. The lipid peroxidation level at different post-irradiation time periods in mouse liver treated or not with Liv.52 before exposure to 3.0 Gy gamma radiation.

Several investigators reported that lipid peroxidation in liver homogenate will start as soon as the supply of endogenous GSH is exhausted, and that the addition of GSH promptly stops further peroxidation[30,31]. It has been reported that the addition of GSH markedly inhibits lipid peroxidation in isolated rat liver microsomes[32].

The administration of Liv.52 before irradiation inhibited the lipid peroxidation significantly as compared to the irradiated control. These results are in accordance with the findings of other investigators, who reported a significant decrease in lipid peroxidation, followed by an increase in the tocopherol level in Liv.52-treated group compared to the CCl_4-treated group[15,16]. Similarly, calmodulin antagonists have been found to inhibit the radiation-induced lipid peroxidation[28]. A depletion in lipid peroxidation was observed in mice erythrocytes treated with MPG before irradiation[29]. WR-1065 and GSH were found to be effective inhibitors of mitochondrial lipid peroxidation induced by HDP/Fe/NADH or by ADP/Fe/ascorbate[33].

Saxena *et al.*[15] reported an increase in the α-tocopherol level in Liv.52-treated rats. In the present study the radiation-induced lipid peroxidation was inhibited significantly by Liv.52 treatment, and this may be due to the elevation of α-tocopherol.

Vitamin E (α-tocopherol) and glutathione are involved in the termination mechanism of lipid peroxidation. Vitamin E donates the hydrogen atom from the chromanol ring hydroxyl group to the lipid radical, generating a tocoperoxy radical. The rate of reaction of vitamin E with lipid hydroperoxy radicals is much faster (~ 10^4) than the rate of reaction of lipid hydroperoxy radicals with neighbouring polyunsaturated fatty acids, thus preventing further damage. Therefore, vitamin E acts as an effective chain breaker, curtailing progression of the lipid peroxidation. However, vitamin E is very low for serving as a lipid radical scavenger, and its concentration in the membrane would rapidly become vanishingly small to reduce the tocoperoxy radical back to tocopherol. Liv.52 may provide α-tocopherol to reduce the tocoperoxy radicals to tocopherol, thereby inhibiting the formation of lipid peroxidation.

Therefore, it is reasonable to assume that radioprotective activity of Liv.52 may be due to the inhibition of lipid peroxidation by increasing the level of α-tocopherol and glutathione.

An onshore gas well blow-out and its impact observations using satellite data

K. V. S. Badarinath, A. T. Jeyaseelan*, C. S. Jha, Biswadip Gharai and C. B. S. Dutt

Forestry & Ecology Division, *Water Resources Group, National Remote Sensing Agency, Balanagar, Hyderabad 500 037, India

The blow-out of the ONGC Gas Well-19 located at Pasarlapudi in East Godavari District, Andhra Pradesh, attracted lot of concern on its impacts. The blow-out site has been monitored by satellite-based data sets from Indian Remote Sensing Satellite (IRS-P2) and Landsat-5 for impact assessment studies. The satellite data sets showed signature variation in 200 m surrounding the well site. The water umbrella formed over the blow-out site and the resultant temperature and humidity variation measured on the ground were significant up to 200 m radius. Satellite-based optical data have been used for estimating the well temperature. The gas well temperature estimated from satellite data has been found to be around 1100°C. The methodology adopted for estimating the gas well temperature and the results on impact assessment studies are discussed.

THE blow-out of ONGC onshore Gas Well-19 located at Pasarlapudi near Devarlanka in Amalapuram Taluk of East Godavari District, Andhra Pradesh, occurred on 8 January 1995. At about 6.50 PM on that day, there was a sudden increase of gas pressure and the casting was pushed out, with the result that the well caught fire. Initially for about 30 days only the vertical spread of the flame was noticed and subsequently due to damage in the blast of preventor (BOP), which is a vertical structure containing equipment for closing the well in case of exigency, the fire in horizontal direction also increased. Satellite data sets over the region were continuously monitored to obtain cloud-free data over the region and first cloud-free coverage was observed in Indian Remote Sensing Satellite (IRS-P2) pass of 27 January 1995. Spaceborne sensors due to synoptic and repetitive coverage provide data over large regions and have the advantage of providing data over inaccessible regions. The sensors onboard natural resources monitoring missions operate mostly in visible and near-infrared regions of the electromagnetic spectrum. The Landsat satellite data in India are acquired with thematic mapper (TM) sensor having a band in thermal IR region of the electromagnetic spectrum. The thermal band data can be used to study temperature variations below 60°C (ref. 5). In the present study, optical data from IRS-P2 and Landsat TM have been analysed with a view to study the impacts due to blow-out, and ground-based measurements have been collated with the satellite-based obser-

vations. IRS-P2 optical data has been analysed with a view to estimate the well temperature and the methodology adopted has been discussed in detail.

IRS-P2 Linear Imaging Self-Scanning System (LISS-II) digital data of 27 January 1995 and Landsat TM data of 2 February 1995 over the blow-out region have been obtained. Biophysical parameters like leaf temperature, photosynthetically active radiation (PAR), leaf level transpiration and intercellular CO_2 were measured using a leaf chamber analyser (LCA-3); temperature and humidity at different points from the well site were also measured. The vertical profiles of temperature and humidity were measured, respectively, with mercurial thermometer having a sensitivity of 0.1°C in the 0–100°C range and with hygrometer using a stack.

The IRS-P2 LISS-II sensor operates in four bands at 0.45–0.52 μm, 0.53–0.59 μm, 0.63–0.69 μm, 0.77–0.86 μm and Landsat TM operates in seven spectral bands (six in 0.45–2.35 μm region and one in 10.4–12.5 μm thermal IR region).

Satellite data sets recorded in various bands can be analysed for vegetation vigour by ratioing the data of infrared and red bands. The ratio is normally called normalized difference vegetation index (NDVI) and is given by the formula NDVI = (IR-Red)/(IR+Red) (refs 1,4).

The thermal IR data of Landsat are used mainly for studying temperatures below 60°C. In the present study an alternate method for estimating the temperature of the gas well has been adopted[5]. The short wavelength region of 0.4–3.0 μm is not commonly used for monitoring the normal thermal regime of the earth's surface as it emits a very small quantity of radiation in this spectral region. In the case of gas well burning, the observed high-temperature region acts like a source of radiation and the radiance values recorded by satellite-based sensors correspond to the emitted radiation. This concept enables the use of Planck's function for estimating the temperature over the gas well. Similar studies have been reported in the literature over volcanic regions[2,3,5].

The false colour composite of the study area generated from TM bands 4, 3, 2 (RGB) is shown in Figure 1 *a* and that from TM bands 4, 5, 7 is shown in Figure 1 *b*. The enlarged false colour composites corresponding to these are shown in Figures 1 *d* and 1 *e*, respectively. The blow-out region can be clearly seen as a bright yellow spot in Figure 1 *d*, which is an enlarged image of Figure 1 *a*. In Figure 1 *b*, severe stress over the vegetation due to heat from blow-out is indicated by bluish grey area around the well site as the TM bands

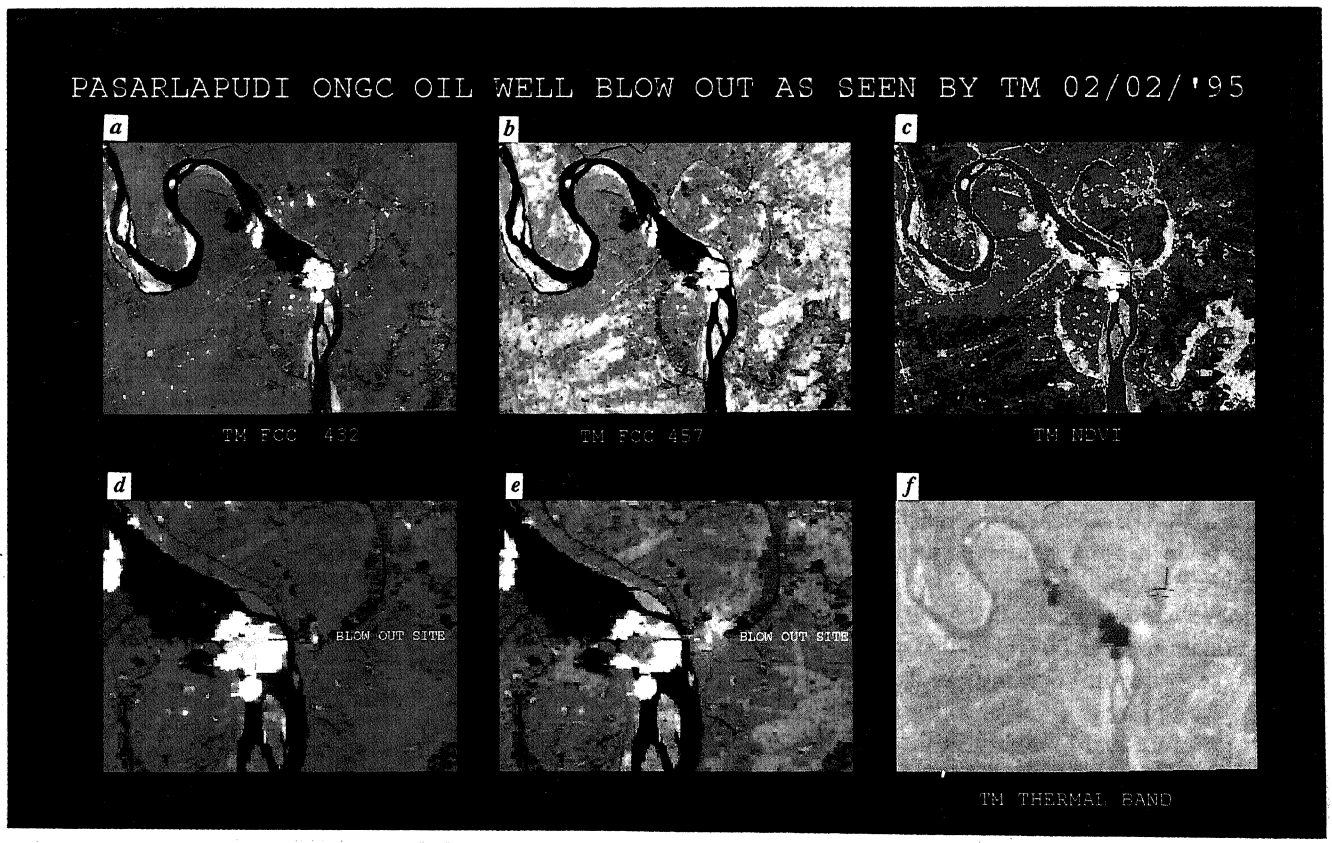

Figure 1. Thematic mapper data of the study area on 2 February 1995: *a*, False colour composite (FCC) of bands 4, 3, 2; *b*, FCC of bands 4, 5, 7; *c*, normalized difference vegetation index (NDVI); *d*, enlarged FCC of bands 4, 3, 2; *e*, enlarged FCC of bands 4, 5, 7; *f*, thermal IR image.

4, 5, 7 (0.77–0.86 μm, 1.55–1.75 μm and 2.08–2.35 μm) are sensitive to vegetation stress. The NDVI image generated from bands 4 and 3 (0.77–0.86 μm and 0.63–0.69 μm) is shown in Figure 1 *c*, wherein the nongreen area around the blow-out site indicates the stressed area. The thermal image of TM band 6 (10.4–12.5 μm) is shown in Figure 1 *f* and it can be observed that due to saturation of thermal radiance values above 60°C, the blow-out site region appears bright and it is difficult to pinpoint the well site.

The satellite observations of localized vegetation stress around the well site were cross-checked with ground observations. Ground measurements of air and soil temperature, humidity, crop photosynthetic rate, transpiration and radiation near the well site were made using the LCA-3 instrument. Further, discussions with Revenue, Agriculture and ONGC officials were made to understand the economic impacts.

The satellite data analysis indicates localized damage of around 200 m close to the well site, as can be seen in Figure 1, and is in conformity with ground observations. The ground observations showed that the temperature was around 40°C at 24–30 f height close to the well site (150 m) and the ground temperature was at 32°C. The temperature was uniform with surroundings beyond 150 m, mainly due to the heat protection by coconut plantations. The well site (BOP) was totally provided with water umbrella by ONGC using jet pumps. The moisture thus generated formed a localized cloud and can be seen as a cloud patch appearing in bright white in Figure 1. The biophysical parameters showed normal values in standing paddy crops close to the blow-out site (150 m) as the ground temperatures were normal and sufficient stagnated water was available in the fields. The coconut trees within 200 m radius showed damage signs as the temperatures were high above ground level due to the gushing flames. The coconut saplings facing BOP at 150 m distance showed yellowing and browning due to damage of leaves. In the leeward side of BOP, healthy coconut saplings are observed. The persistent high temperature of above 40°C at the coconut crown led to falling of fruits near the BOP site (200 m). The heat-tolerant Ficus sp. plant was found to be in healthy state even at a distance of 150 m from the well site.

The observations made by A. P. Pollution Control Board, Rajahmundry, indicated that no poisonous gases were present due to burning in the atmosphere. The physiological process level changes due to exposure to high temperature and humidity in the less impacted area were also shown to be normal. Noise pollution was in the range of 100–140 dB close to the well site and 55 dB (normal) around 2 km radius, as reported by A. P. Pollution Control Board.

The temperature of the well site was estimated to be around 1100°C; this value is close to the reported values. The effect of emitted gases and water vapour on the satellite-derived radiance values has not been considered while calculating the temperature. The ground temperature and humidity variation at different heights from the well site is shown in Figure 2. It can be observed that the temperature values are increasing with height, due to the gushing flames spreading above ground level. Due to water umbrella, the humidity values were found to be high in the windward direction away from the well site.

The analysis of satellite data suggested localized effects (around 200 m regions) due to the oil well blow-out. The temperature values estimated from the optical data are in conformity with ONGC ground observations, suggesting the possible use of optical data for studying high-temperature phenomena. The noise pollution levels are high within 2 km region around the site. The damage to coconut plantations in down wind direction were

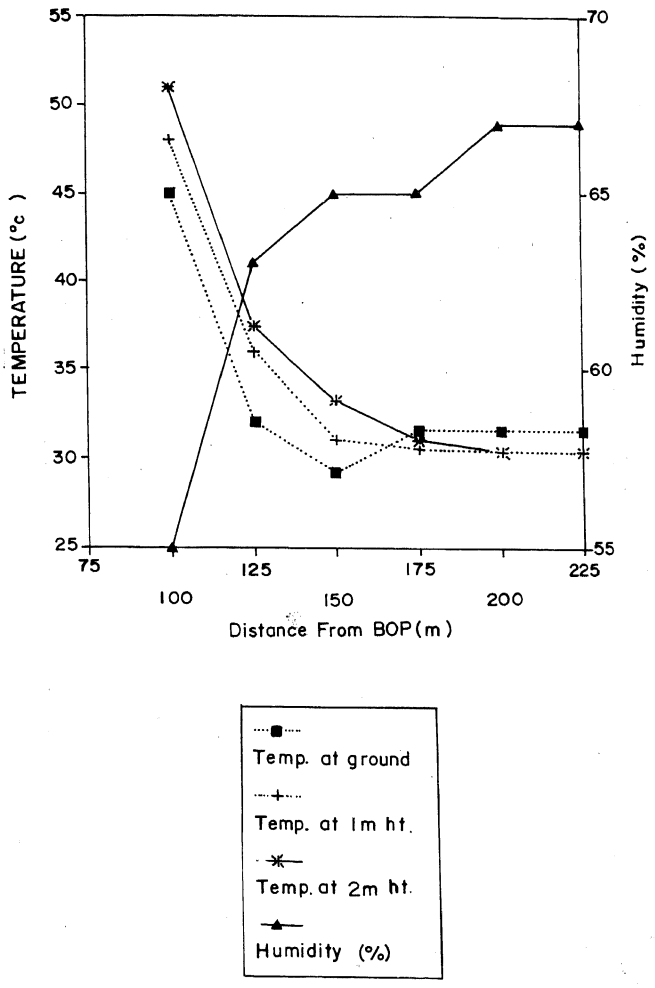

Figure 2. Temperature and humidity profiles at various points from the blow-out site.

observed within 200 m zone. The area under 200 m radius from BOP is the zone of influence of blow-out. The gas blow-out site was inaccessible and satellite data alone facilitated in observing the vent temperature synoptically during the blow-out condition. In addition, multitemporal satellite data by virtue of repetitive coverage facilitated dynamic aspects of blow-out condition and the associated spatial changes resulting due to damage. Thus, satellite technology only could facilitate synoptic observation of such episodic events and could account spatially for the area of its influence.

Oxygen linkages in neodymium heptamolybdate single crystals – An XPS study

Sushma Bhat, P. N. Kotru and K. S. Raju*

Department of Physics, Jammu University, Jammu 180 001, India
*Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Madras 600 025, India

Single crystals of neodymium heptamolybdate ($Nd_2Mo_7O_{24} \cdot 27H_2O$) are grown in sodium metasilicate gel by the diffusion of neodymium nitrate (upper reactant) into the set gel impregnated with a mixture of molybdenum trioxide, ammonium hydroxide and concentrated nitric acid (lower reactant). Oscillation X-ray diffraction pattern shows that neodymium heptamolybdate is single-crystalline in nature, while infrared absorption spectrum establishes the presence of molybdate group and water of crystallization. X-ray photoelectron spectroscopic studies of neodymium heptamolybdate single crystals establish the presence of neodymium and molybdenum in their oxide states and the oxygens in the sample are shown to exist as (i) terminal oxygen (Mo=O), (ii) bridging oxygen (Mo–O–Nd) and (iii) oxygen of lattice water (H–O–H).

FERROELECTRIC and ferroelastic properties of rare-earth molybdates are of great interest in electro-optical and acousto-optical devices[1–3]. Barium molybdate tetragonal bipyramidal crystals are grown by the precipitation of alkaline-earth metal molybdate powders from neutral aqueous solutions[4]. Rare-earth molybdates, having the general formula $R_2(MoO_4)_3$, have been reported to be ferroelectric materials[5]. The growth of rare-earth molybdates (R = Pr, Nd, Sm, Eu, Tb and Dy) using the Czochralski technique has been studied by Brixner[6]. As this method involves elevated temperatures, thermal stresses released during the growth may make the crystals defective. Henisch and coworkers[7,8] have established the growth of crystals in gels and this method has been fully exploited in the case of calcium sulphate dihydrate single crystals[9–15]. Growth and characterization of rare-earth mixed single crystals of samarium barium molybdate have been reported by Isac and Ittyachen[16]. Studies on the growth of neodymium heptamolybdate (hereafter called NHM) single crystals in silica gels have been reported in the literature[17].

For the growth of NHM in gels in the test tube, acidified aqueous solution of sodium metasilicate (0.5 M, pH 5) is used as the reacting medium. The lower reactant (to be incorporated inside the gel before setting) is prepared as follows: 0.5 M molybdenum trioxide is completely dissolved in 15 N ammonium hydroxide using a magnetic stirrer, to which nitric acid (24 ml in 50 ml distilled water) is added. This lower reactant is mixed with the above gel and allowed to set undisturbed (gel age 96 h). On top of this set gel, as the upper reactant, a solution of 0.75 M neodymium nitrate is slowly added through the wall of the test tube, so as not to rupture the surface of the set gel. In about three weeks' time, platelets of NHM (of sizes 2 mm × 2 mm × 1 mm) appear below the thick white layer of the precipitate (of NHM) inside the gel.

The mechanism of chemical reactions leading to the formation of NHM is explained as follows:

$$MoO_3 + 2NH_4OH \rightarrow (NH_4)_2 MoO_4 + H_2O. \quad (1)$$

When acidified, we get

$$(MoO_4)^{2-} + H^+ \rightarrow HMoO_4^- , \quad (2)$$

$$HMoO_4^- + H^+ + 2H_2O \rightarrow Mo(OH)_6 , \quad (3)$$

$$Mo(OH)_6 + HMoO_4^- \rightarrow (HO)_5 MoOMoO_3 + H_2O, \quad (4)$$

$$(HO)_5 MoOMoO_3^- + HMoO_4^- \rightarrow (HO)_4 Mo(OMoO_3)_2^{2-} + H_2O, \quad (5)$$

*For correspondence.

$$(HO)_4\,Mo(OMoO_3)_2^{2-} + 3HMoO_4^- \rightarrow (HO)\,Mo(OMoO_3)_5^{5-} + 3H_2O, \quad (6)$$

$$(HO)\,Mo(OMoO_3)_5^{5-} + HMoO_4^- \rightarrow Mo(OMoO_3)_6^{6-} + H_2O, \quad (7)$$

$$Mo(OMoO_3)_6^{6-} \rightarrow Mo_7O_{24}, \quad (8)$$

$$2Nd^{3+} + Mo_7O_{24}^{6-} \rightarrow Nd_2Mo_7O_{24}. \quad (9)$$

The oscillation X-ray diffraction (XRD) pattern (Figure 1) of NHM platelet was recorded in a Unicam camera with Cu K_α radiation ($\lambda = 1.5418$ Å). The revelation of well-defined Bragg reflections at specific (2θ) angles confirms that NHM is ordered, meaning single crystalline, in nature.

The IR absorption spectrum of NHM taken in KBr matrix confirms the presence of the water of crystallization by the well-defined broad peak at 3000–3600 cm^{-1} (relating to antisymmetric and symmetric OH sretchings) and a peak at 1630 cm^{-1} (relating to HOH bending). The presence of molybdate groups in NHM is also established by the revelation of a pronounced broad peak at 810 cm^{-1} relating to symmetric or antisymmetric stretching modes of vibration[18] and a peak at 325 cm^{-1} relating to symmetric bending modes of vibration[19].

It is worth mentioning, that in the present work, so far, neither XRD nor infrared (IR) absorption spectrum has been able to identify heavy elements like Mo and Nd unambiguously. Hence, it was thought worthwhile to take up the most sophisticated X-ray photoelectron spectroscopic (XPS) technique.

In XPS (more commonly known as ESCA), the identification of the elements incorporated in the sample is established from the binding energy (BE) values (eV) relating to the peaks of their respective elements, while the quantitative data are obtained from the peak heights or areas. The chemical states of the elements were identified from the exact positions and separations of the peaks, as well as from certain spectral contours. XPS studies were carried out on NHM single crystals in order to confirm the presence of heavy elements (Nd and Mo in the present case) besides their chemical states, which, consequently, sheds information on the linkages of the oxygens as well.

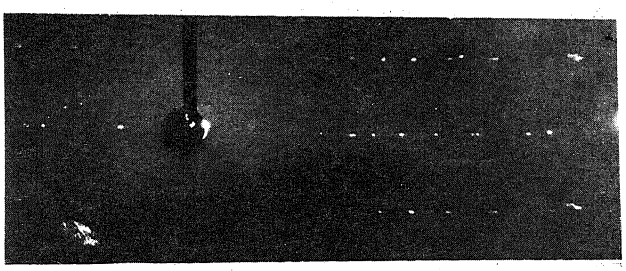

Figure 1. Oscillation XRD pattern of NHM.

The XPS investigations of NHM were carried out at the Regional Sophisticated Instrumentation Centre, Indian Institute of Technology, Powai, Bombay, using a system VG scientific ESCALAB MK2 spectrometer (Al K_α source, photon energy 1486.6 eV) operated at 10 kV and 10 mA. The overall resolution of the system with an analyser pass of 50 eV is about 0.7 eV. The pressure in the analyser chamber was maintained below 10^{-9} torr.

In the present investigations, the BE (eV) scale (X-axis) was calibrated for C 1s (284.6 eV), which is due to the contribution of adventitious hydrocarbon from the laboratory environment or from the glove box.

The XPS peaks relating to Mo 3d states (Figure 2 *a*) are positioned at BEs of around 232.5 and 235.7 eV, with the separation of 3.2 eV strongly suggesting that Mo in NHM is in the oxide state (MoO_3). Similarly, the XPS peak relating to $3d_{5/2}$ state of Nd (Figure 2 *b*) in NHM has a BE of around 980 eV. This BE value confirms that Nd too is in its oxide state (Nd_2O_3) in the NHM sample, which is in good agreement with literature findings[20] on the structural characterization of

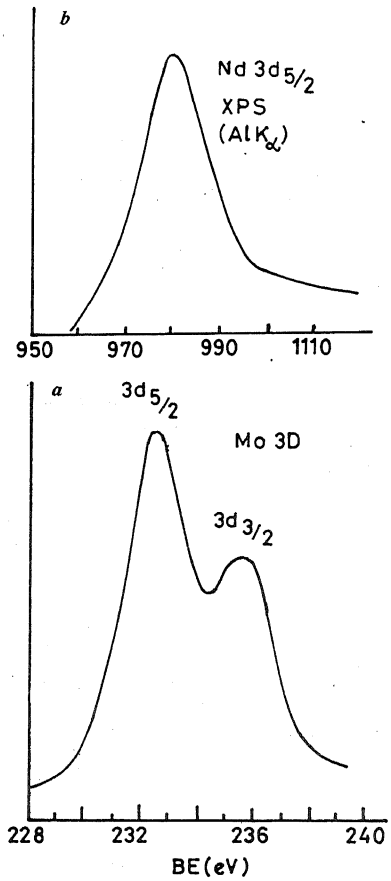

Figure 2. XPS peaks of (*a*) 3d levels of molybdenum and (*b*) $3d_{5/2}$ level of neodymium.

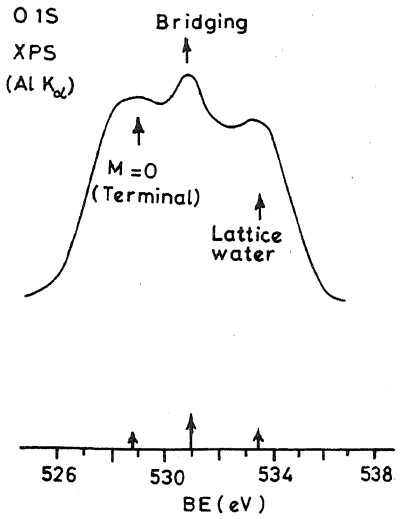

Figure 3. XPS peak of oxygen 1s.

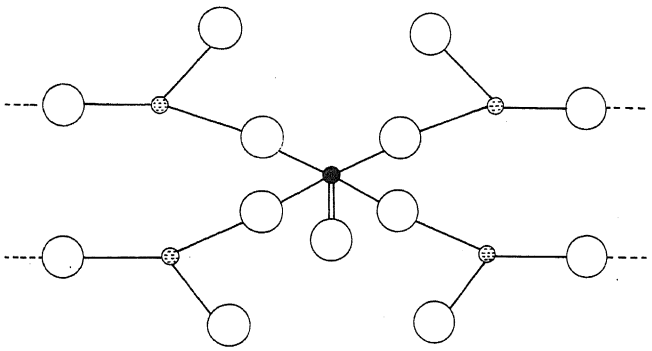

Figure 4. Schematic of oxygen coordinations in NHM: molybdenum (small dark circle), neodymium (small dashed circles) and oxygen (big blank circles).

gel-grown neodymium copper oxalate single crystals.

It is interesting to note that the XPS peak relating to O 1s (Figure 3) has a complex spectral contour and is a broad peak comprising of three peaks. These peaks relate to BEs around 528.8, 531 and 533.5 eV, respectively, giving the clue that oxygens in NHM have three different coordinations.

The incorporation of Mo, Nd and O in NHM has been confirmed by XPS (Figures 2 and 3) besides establishing the existence of Mo and Nd as their oxides (Figure 2 *a*, *b*). These conclusions are strongly supported by the binding energy values corresponding to XPS peaks of Mo(3d), Nd($3d_{5/2}$) and O(1s) (Figures 2 and 3), which are in excellent agreement with literature findings[21].

Attention is drawn to the fact that the chemical formula for NHM ($Nd_2Mo_7O_{24}$) as arrived at from the mechanism of reaction kinetics (eqs (1)–(9)) seems reasonable, as to be having the entities (Nd_2O_3) and 7(MoO_3), as supported by the XPS peaks of Nd and Mo in their oxide states (Figure 2). The possible oxygen linkages with MoO_3 and Nd_2O_3 in NHM are shown schematically in Figure 4. A careful examination of Figure 4 reveals that oxygens have two types of linkages, namely, terminal oxygen (Mo=O) and bridging oxygens (Mo–O–Nd). In order to account for the third entity, i.e. water of crystallization, the third peak in the complex spectral contour of XPS of O 1s (Figure 3) is attributed to the oxygen getting coordinated to the hydrogens of lattice water (H–O–H), whose presence is confirmed by the IR absorption spectrum of NHM. Thus, XPS studies throw light on the presence of Mo, Nd and O as well as on their chemical states, confirming the speculation of the entities of NHM as MoO_3, Nd_2O_3 and lattice water. Besides this, complex spectral contour of XPS peak of O 1s has been helpful in understanding the linkages of oxygens in NHM as well (Figure 4).

The heights and/or areas of XPS peaks, meaning their intensities, are measures of the quantities of the species present in the material[22]. It is clearly evident from Figure 3 that the intensity of O 1s relating to bridging oxygens is higher than that of terminal oxygens. Hence, it may be concluded that, from the viewpoint of structural aspects, the contribution of the bridging oxygens is more significant than that of the terminal oxygen in NHM.

Tectonic evolution of the Central Gujarat plain, western India

D. M. Maurya, L. S. Chamyal and S. S. Merh

Department of Geology, Faculty of Science, M.S. University of Baroda, Baroda 390 002, India

The Quaternary basin of the Gujarat plain is formed due to the reactivation of Tertiary basement faults. The uplift as a horst of the Aravalli in the east and the Saurashtra peninsula in the west, comprising a culminating event of the post-Mesozoic rifting of the western continental margin, resulted in the Quaternary basin which was later filled up by alluvial sediments. The basin that received the fluvial sediments marked the end phase of the Cambay graben subsidence that was initiated in the Paleocene. The nature of variation in thickness of the Quaternary sediments in its different segments indicates that the basin comprised a series of horsts and grabens. Whereas the Early Quaternary tectonism gave rise to the differential basement topography, the tectonic events of the Late Quaternary were responsible for the present landscape development in Central Gujarat.

THE 300–800 m thickness of Quaternary fluvial and aeolian sediments resting upon the Tertiary rocks of the Cambay basin is the consequence of reactivation of pre-Quaternary basement faults. The Quaternary basin is delimited by marginal faults in the west and east. To the SE lies the Narmada–Son Lineament, and in the NE is the Aravalli horst (Figure 1). The basin comprises several fault-bound structural blocks[1] which continue up to Moho boundary[2]. The Gujarat Quaternary sediments have been studied by several workers (Allchin *et al.*[3], Chamyal[4], Chamyal and Merh[5], Merh and Chamyal[6] and Pant and Chamyal[7]); their emphasis, however, was mainly on the processes and agents of deposition, and on the paleoclimatic variations recorded in sediments. Recent work has demonstrated that successive tectonic events in the Gujarat region since Cretaceous[8] have also controlled the pattern of sedimentation and nature of the sediment body. The Cambay and Narmada basins, according to Biswas[8] opened up as a result of the counterclockwise rotation accompanying drift of the Indian plate.

The Gujarat plains, in the light of the overall Cambay basin tectonics, point to an important role played by differential movements along numerous structural lineaments in controlling the process of filling up of the Quaternary basin and sculpturing the present-day landscape. The movements along tectonic lineaments at various scales are significantly reflected in (i) the disruption of an ancient superfluvial system and its replacement by the existing drainage[9], (ii) development of ravines along various river courses indicating post-depositional fracturing, (iii) differential altitudes of river terraces, (iv) capturing of rivers (e.g. Rupen by Sabarmati, Orsang by Narmada), (v) differential uplifts along most major rivers giving rise to a distinct northward tilting of the respective left banks, and (vi) progressively increasing subsidence from south to north[10].

We have for the first time attempted to interpret the role of tectonics in the evolution of the Quaternary basin and its subsequent filling. Obviously, the Quaternary sedimentation is found to have been controlled by the same tectonic features which were responsible for the deposition of the Tertiaries. With the withdrawal of the Tertiary sea in this part, marine processes were replaced by fluvial sedimentation, marking the onset of the nonmarine continental depositional cycles. The marine sediments of Upper Tertiary show a transition[11] changing over to a period dominantly of fluvial sedimentation during the Quaternary.

The basin that received Quaternary sediments, obviously, comprised the more or less filled up Tertiary Cambay basin and marked the culminating phase of the Cambay and Narmada graben tectonics, though the tectonism preceding, during and post-dating the continental deposition was an integral part of the Cambay basin tectonism. ONGC investigations have adequately shown that the Cambay basin formed during Paleocene subsided episodically with varying rates and finally during Quaternary the rate of subsidence slowed down. It is however, not unlikely that the Quaternary basin experienced considerable reactivation of the pre-existing faults. These faults were an integral part of the Cambay basin rift phenomenon. It is possible that the advent of Pleistocene witnessed a renewal of tectonic activity and triggering of a new cycle of subsidence. This neotectonism coincided with the uplift of Aravalli in the east and northeast[12]. An uplift of the order of 300 m of the Aravalli has been envisaged by Ahmad[13] during Quaternary. To

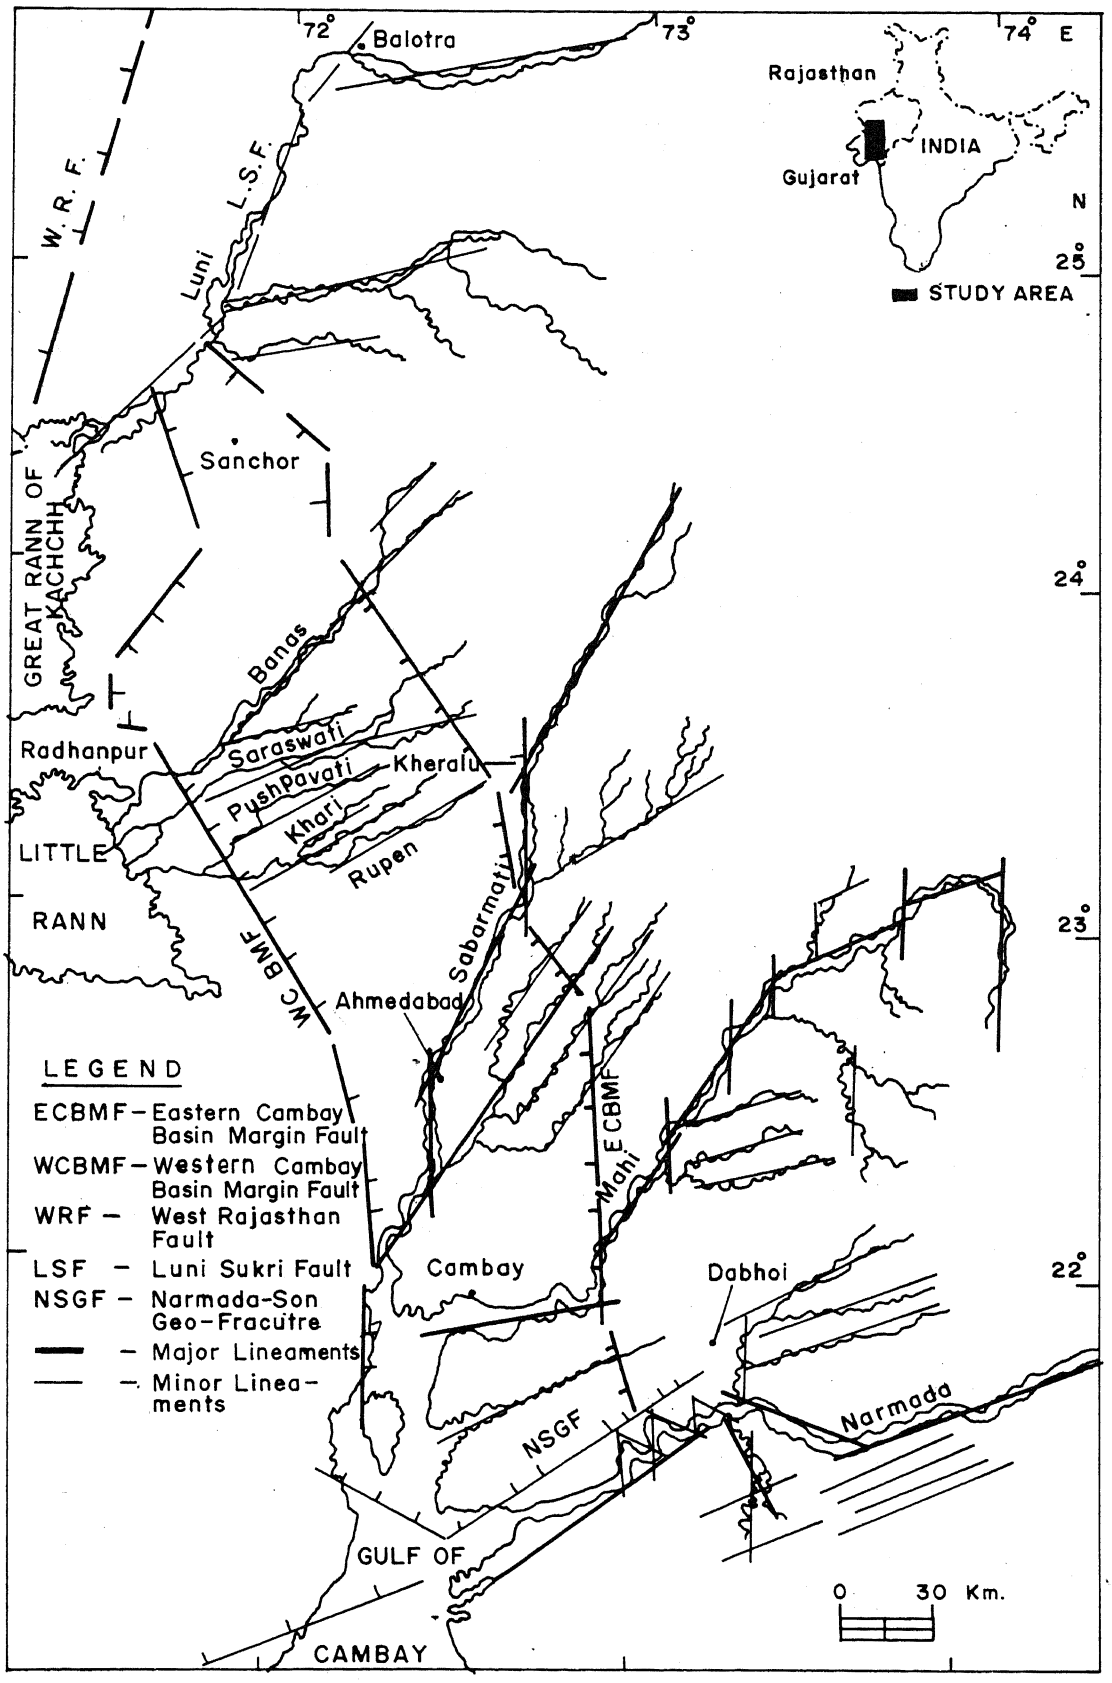

Figure 1. Tectonic map of the Gujarat alluvial plain superimposed over the tectonic map of Cambay basin[14].

the west, the Saurashtra peninsula formed an uplifted horst (Figure 2). This renewal of tectonic activity was essentially related to the Cambay basin faulting and the Narmada geofracture.

The development of a rift-related depression in front of a rising hill range provided an ideal site for the initiation of fluvial sedimentation. The exposed river sections as well as subsurface data provide clear and unequivocal evidences pointing to an enormous thickness varying from about 800 m in the south to 300 m in the north. The variation in thickness is controlled by basinal faults which were effective prior to and during the sedimentation. Significantly, colluvial deposits are absent and fluvial material is encountered right from the rocky fringes. Although the sediment thickness varies from block to block (Figure 3), in composition the fluvial sediments comprise gravels, coarse to fine sands, silts and clays, and point to their deposition in several instalments, depositional process punctuated by periods of nondeposition and pedogenesis. The sediment nature and thickness point to an overall basin subsidence, but one cannot be very sure about the variations in the movement and in the course of Quaternary too, it is not unlikely that inversions in movement directions did take place. Such a tectonic pattern has been established for the trappean highlands of South Gujarat by Alavi and Merh[10], and similar post-Tertiary tectonic activity can safely be visualized.

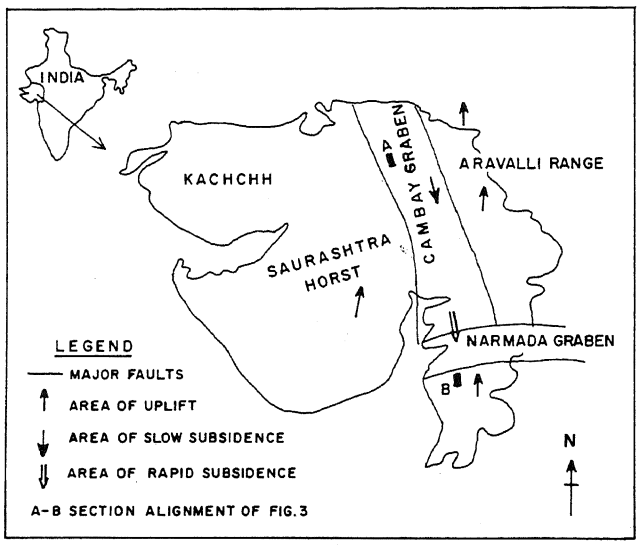

Figure 2. Sketch map of Gujarat showing major tectonic movements during Quaternary.

The cross-section prepared based on ONGC data clearly brings out the influence of the tectonic framework of the Cambay and Narmada basins along with their various tectonic blocks on the Quaternary sediments (Figure 3). The basin therefore, comprised series of horsts and grabens which were the direct manifestations of the various Tertiary structural blocks. These tectonic sub-basins were subjected to periodic uplifts and subsidences relative to each other, while overall the basin was subsiding. Whereas the ONGC workers have worked out in considerable detail the role of tectonics in Tertiary sedimentation, no information was provided by them on the Quaternary history. There is, however, little doubt that the Late Quaternary tectonism has been responsible for the present landscape development in Central Gujarat.

Occurrence and petrogenesis of Loda Pahar trondhjemitic gneiss from Bundelkhand craton, central India: Remnant of an early crust

Kewal K. Sharma and Abdul Rahman

Wadia Institute of Himalayan Geology, Dehra Dun 248 001, India

The occurrence and the geochemistry of the typical high-Al trondhjemitic gneiss intruding into the highly deformed basic host rocks from Loda Pahar, Kabrai area, northeastern part of the Bundelkhand massif is reported. This large relict of the early crust is intruded by various phases of Proterozoic calc-alkaline granitoids. The highly fractionated REE pattern with HREE depletion and concave upward shape at the HREE end of the Loda Pahar trondhjemitic gneiss (LPTG), besides the major and trace element chemistry, is typical of Archaean TTG suites reported from shield areas of other continents. The evolution of such trondhjemitic magma is considered to have played a significant role during early crustal growth and the LPTG provides the first convincing evidence to qualify the Bundelkhand craton as a typical Archaean terrain.

IN recent years considerable work has been done to understand the nature and evolutionary trends in the formation of early crustal rocks, the relicts of which are exposed in shield areas of all the continents. The Archaean crust in general is comprised of granitoid gneisses, massive granitoids and greenstones in proportion of 6 : 3 : 1[1]. The evolutionary trends recognized in the granitoid rocks of the Precambrian terrains of the world contain two main associations, an older Na-rich tonalite–trondhjemite–granodiorite (TTG) suite and younger K-rich granodiorite–monzonite–adamellite–granite (GMAG) suite. The former predominates throughout the Archaean, but subsequently, the latter becomes significant. The chemical and isotopic characters of the two suites are distinct and provide a major temporal demarcation in continental evolution at the Archaean–Proterozoic boundary[1].

In India, evidence to reconstruct different stages of early crustal evolution have so far come from the cratonic nucleii of Dharwar, Singhbhum and very recently from Bastar. Though the Bundelkhand craton is being considered unique for representing an early crust, unaffected by Proterozoic and subsequent deformational events[2], there is no convincing geochemical or geochronological data to indicate the presence of an early crust from Bundelkhand craton except for the geochemical data of early Proterozoic Bundelkhand granitoids[3].

The authors initiated detailed petrochemical studies of the Bundelkhand craton and have identified different components (metabasic and metasediments with banded iron intruded by various phases of TTG) of the early crust into which the Proterozoic calc-alkaline granitoid suite intrudes. The present paper reports the occurrence of a large relict block of trondhjemitic gneiss in deformed Archaean crust intruded by undeformed early Proterozoic calc-alkaline granitoids from Loda Pahar, Kabrai area. It also discusses the geochemistry, petrogenesis and its implication to the evolution of the Archaean crust in the Bundelkhand craton of the Central Indian Shield.

Semicircular to triangular outcrop of Bundelkhand granite massif in the northern part of the Indian Shield is known to be comprised dominantly of granitoid plutons of various phases, younger basic dykes and quartz reefs, mainly the early Proterozoic magmatic events. The information on the nature of the Archaean crust into which the younger Proterozoic granitoids intruded is very much limited to the reported occurrences of numerous enclaves of schists, gneisses, banded iron, calc-silicates, mafic and ultramafic rock suites only[4].

Recently, Rahman and Zainuddin[3] identified five phases within the Bundelkhand massif and provided geochemical data to characterize their source rock from Mahoba area. The earliest phase of the hornblende-bearing granodiorite having metaluminous composition and Y depletion has been attributed to hydrous partial melting of hornblende- and/or garnet-bearing mafic source. The

porphyritic varieties of the biotite granite which intrude into the hornblende granodiorite are Y-undepleted, I-type, monzo-granites and were generated from the melting of the felsic crust. The subsequent intrusion of two phases of younger leucogranites (coarse and fine-grained varieties) are peraluminous monzo- to syno-granite and show marked enrichment with Y, Zr, Th, K and Rb and depletion of P, Sr, Ti and Ba. The magma for these leucogranite phases corresponds to the highly fractionated calc-alkaline to alkaline composition and felsic I-type granite characteristics. Following the preliminary geochronological age of 2550 Ma (based on Rb–Sr whole-rock isochron of seven samples collected from widely separated areas from the massif) for the Bundelkhand granite by Crawford[5], Sarkar *et al.*[6] carried out detailed Rb–Sr whole-rock dating of various plutons exposed in the northwestern part (Jhansi–Babina track). Six whole-rock samples of grey granodiorite–granite suite from a quarry define a Rb–Sr isochron age of 2359 ± 53 Ma with initial Sr ratio Sr_i of 0.7082 ± 0.0036. Another set of five whole-rock samples of pink-coloured coarse-grained granite–granite porphyry–aplite suite from Babina–Talbehat yielded a Rb–Sr isochron age of 2246 ± 78 Ma with Sr_i ratio of 0.7125 ± 0.0045. Four whole-rock samples of Badera gneissic migmatites (southeast of Babina) yielded a Rb–Sr isochron age of 2130 ± 102 Ma, possibly reflecting a strong thermal imprint due to large-scale emplacement of younger (pink) granite phase rather than the true age of the formation of the gneissic component of the older crust. However, the Geological Survey of India has dated 3.5-Ga-old gneissic rock from Babina–Talbehat area[7].

The authors during their initial field studies recognized numerous xenoliths of highly folded gneissic rocks within

the undeformed hornblende granodiorite phase exposed on the hillocks west of Mahoba railway station. Following these occurrences of older gneissic relicts in early Proterozioc intrusive granite phases, large exposures of older gneissic rocks (representing the Archaean crust) were delineated along Mahoba–Charkhari and Mahoba–Kabrai roads. One such large gneissic block (1 km long and 500 m wide) with associated metabasics is exposed around the Loda Pahar hillock, east of Kabrai, near the junction of Kabrai–Kanpur and Mahoba–Banda road, and is surrounded by intrusive biotite-bearing porphyritic granite phase. This hillock is 50 m high, the southern face of which has been extensively quarried for road construction material. On the northern slope of the Lodha Pahar, 1 m wide sulphide mineralized shear zone has been observed in the gneissic rocks which runs parallel to its northern contact with the biotite granite. Highly deformed and altered peridotites, and mafic schistose rocks are the host into which the trondhjemitic gneiss intrudes. Clear contact relationships among the various rock units in this area are masked by subsequent granitic activity and soil cover.

The Loda Pahar trondhjemitic gneiss (LPTG) is grey to pink, medium- to fine-grained gneiss with occasional phenocrysts of feldspar having a uniform mineral composition. The rock consists of quartz and plagioclase as dominant mineral with rare presence of K feldspar. Biotite altered to green chlorite is ferromagnesian mineral phase and is aligned parallel to the foliation of the rock. Accessory minerals include small euhedral crystals of Fe–Ti oxides, epidotes, apatite and zircon. All the samples exhibit typical granoblastic fabric modified by cataclastic deformation as evidenced by mortar texture, deformed and rapidly tapering lamellae in feldspars with locally developed myrmekites. The quartz, occurring as linear bands, shows undulose wavy extinction, recrystallized sutured grain contacts, with occasional granulated and polycrystallized fine-grained streaks parallel to the gneissosity.

Seven fresh and representative samples of Loda Pahar trondhjemitic gneiss were selected for geochemistry. All the major and trace elements were determined by XRF (Siemens SRS-3000 sequential X-ray spectrometer) and the rare-earth elements (REE) by AES-ICP at WIHG. The analytical methods for determining REE are similar to those proposed by Walsh[8]. The geochemical data of the LPTG are given in Table 1.

The chemical composition of the LPTG is quite uniform. The rock contains a restricted range of SiO_2 (69.45–70.69%), Al_2O_3 (15.89–16.5%), MgO (0.66–0.82%), .CaO (1.83–2.18%), Na_2O (5.55–6.08%) and K_2O (2.32–2.75%). The rock is poor in ferromagnesian elements ($Fe_2O_3 + MgO + TiO_2 < 5\%$) and has high Na_2O values relative to CaO and K_2O with consistent low K_2O/Na_2O (< 0.5) ratio. The sodic character of the LPTG is indicated by the K–Ca–Na triangular diagram (Figure 1), thus clearly reflecting trondhjemitic trend confirming to the definition of trondhjemite[9]. Further, the LPTG is classified as high-Al trondhjemites in view of its high Al_2O_3 content (> 15%) at 70% SiO_2 (refs 10–12). Its high-Al nature is also substantiated by lower ratio of K/Rb (106–260, av. 176) and Rb/Sr (av. 0.17), low Y (10–13 ppm), Cr (9–21 ppm, av. 14 ppm) and Nb (10–14 ppm), and high Sr (647–910 ppm) content. Similar values have been reported for Archaean high-Al TTG rocks from various continents[11]. Being uniform in major and trace element composition, two samples of LPTG were selected for REE analysis. The consistency of REE data and the highly fractionated $(La/Yb)_N$ (43, 49.6) with depleted Yb_N content (3.83) and concave upward shape at heavy REE (HREE) end without any significant Eu anomaly in the LPTG is remarkably similar to the typical high-Al TTG suite reported from the Archaean[11,13].

As mentioned earlier, the Archaean TTG at 70% SiO_2 level have been divided into geochemically distinct low-Al and high-Al types. This subdivision emphasizes the significant role of hornblende and its retention as a refractory phase in the source rock during partial melting, thereby increasing the Al_2O_3 content in the melt[14]. Various models for the origins of TTG parental magmas have been proposed by the earlier workers; however, the recent geochemical and experimental studies on the Archaean rocks convincingly support the idea of partial melting of garnet-bearing amphibolites[13].

The strongly fractionated REE pattern and HREE depletion in the LPTG magma (Figure 2) suggest that

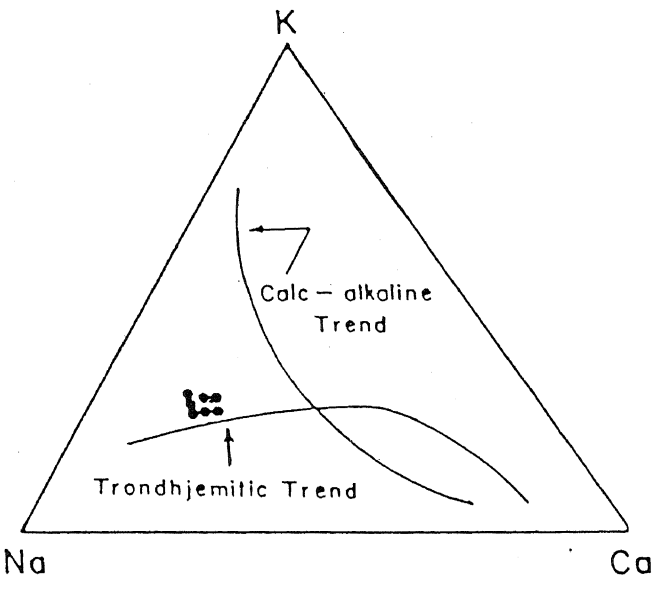

Figure 1. Ternary K–Na–Ca plot for the LPTG samples lying on the trondhjemite trend (from ref. 10).

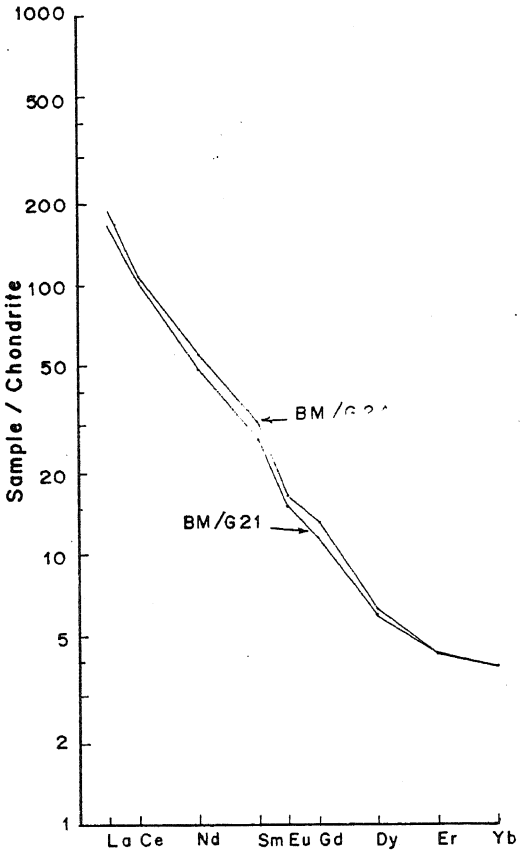

Figure 2. Chondrite normalized REE pattern of LPTG.

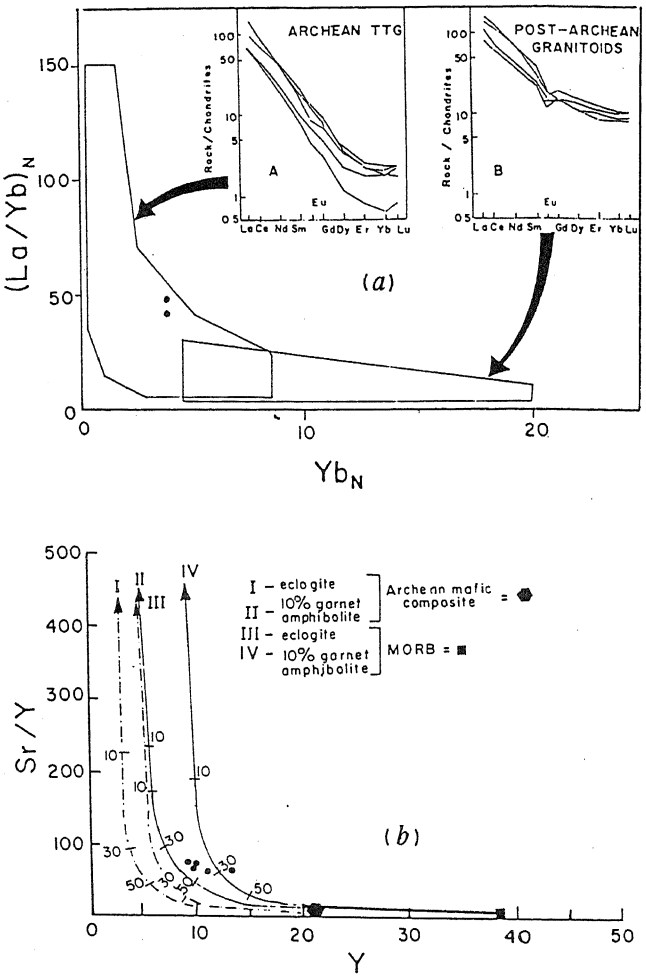

Figure 3. *a*, $(La/Yb)_N$ versus (Yb_N) diagram showing changes in REE contents with time (from ref. 13), the LPTG data plot in the Archean TTG field, *b*, Sr/Y versus Y diagram showing that the LPTG samples have an affinity with 10% garnet amphibolite source (from ref. 11).

hornblende and/or garnet may be the residual phase in the source. Further, the presence of garnet in the hornblende-rich source is implied by the metaluminous composition and the low normative corundum average values of 0.36%. The plots of the LPTG samples on $(La/Yb)_N$ vs Yb_N and Sr/Y vs Y diagram (Figure 3) fall in the Archaean TTG field and suggest the generation of magma by partial melting of the source rock comprised of 10% garnet amphibolite. Such a derivation of trondhjemitic magma is now well constrained by experimental and geochemical data by Martin[12,13], who suggested a three-stage process for their genesis: (i) initial production of a large volume of tholeiitic magma by partial melting of mantle; (ii) metamorphic transformation of this tholeiite into garnet amphibolite and their subsequent partial melting to give rise to the parental magmas of TTG, leaving hornblende + garnet + clinopyroxene + minor plagioclase; and (iii) fractional crystallization mainly of hornblende + plagioclase to produce the differentiated TTG suite. The highly fractionated REE pattern of the LPTG compares closely with the high-Al older metamorphic tonalitic gneiss (OMTG), Champua area of Singhbhum–Orissa craton (3.6 Ga)[15,16]; Markampara trondhjemite from Bastar craton (3.5 Ga)[17]; trondhjemitic gneiss from Satnur–Halagur–Sivasamudram area, Dharwar craton (2.9 Ga)[18] of the Indian Shield; trondhjemitic gneiss from Mount Edger batholith, Pilbara, Australian Shield (3.3 Ga)[19]; Ancient Gneissic Complex, Swaziland (3.0 Ga)[20,21] and Kivijarvi trondhjemitic gneiss from eastern Finland (2.8 Ga)[12]. In view of the remarkable geochemical similarity between the LPTG and other trondhjemitic rocks from different Archaean terrains, it is evident that the likely process of their formation may be the same.

To summarize, the presence of the typical high-Al trondhjemitic gneiss in association with other crustal components as relicts from the Kabrai area provides the first convincing evidence to qualify the Bundelkhand craton as a typical Archaean terrain similar to Singhbhum–Orissa, Bastar and Dharwar cratons of the Indian Shield.

Hypothalamic γ-glutamyl transpeptidase activity in rats following morphine and naloxone treatment

P. Sreenivasan and E. Vijayan

School of Life Sciences, Pondicherry University, Pondicherry 605 014, India

Hypothalamic γ-glutamyl (γ-GT) transpeptidase activity was measured in pubertal and sexually mature male rats. Rats were given subcutaneous injection of morphine and naloxone and the enzyme activity was measured at different time intervals. Morphine had an inhibitory effect on the enzyme activity in both the age groups. Naloxone, an opioid receptor antagonist, had a stimulatory effect on γ-GT activity in pubertal rats while it had no effect in sexually mature rats. This suggests that opiates exert an inhibitory effect on glutathione utilization through γ-GT cycle. Physiological significance of this finding with reference to pituitary function appears to be the suppression of gonadotropin secretion.

GAMMA-glutamyl transpeptidase (γ-GT) is a widely distributed enzyme that functions in the utilization of glutathione by transferring the γ-GT moiety of the tripeptide to amino acid or peptide acceptors. This enzyme together with others plays a major role in the synthesis and degradation of glutathione via the γ-GT cycle[1]. Gamma-GT is a membrane-bound enzyme present in abundance in epithelia of many organs[2,3]. The substrates for the enzyme are glutathione (GSH), oxidized glutathione (GSSG), S-substituted glutathione and other γ-GT compounds. Glutathione's function is to maintain protein thiol groups which may be required for catalysis and is involved in protein assembly and degradation. Glutathione also helps in protecting protein and cell membranes against peroxides and free radicals. Glutathione has also been reported to play a modulatory role on anterior pituitary hormone release[4]. It is probable that glutathione interacts with neuropeptides such as GnRH, opioid peptides and other regulatory elements at the hypothalamic level to elicit an endocrine response. The present study was designed to evaluate whether hypothalamic γ-GT transpeptidase activity responds to treatment with morphine sulphate – an opiate agonist – and naloxone – an opioid receptor antagonist – and thereby affects glutathione metabolism in pubertal and sexually mature rats.

All the experiments were done in colony-bred rats, derived from Wistar strain, purchased from the Animal Facility of Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Pondicherry, and Kind Institute of Preventive Medicine, Madras. Forty (pubertal) and 60 (sexually mature) days old male rats were used in this study. They were maintained under controlled conditions of light (14 h light and 10 h dark) and temperature with free access to drinking water and standard rat pellets.

Morphine sulphate, γ-GT paranitroanilide, glycyl–glycine and naloxone were obtained from Sigma Chemical Co., St Louis, USA. Naloxone (2 mg/kg body weight, dissolved in 0.9% saline), morphine sulphate (2 mg/kg body weight dissolved in 0.9% saline) were injected subcutaneously. All the doses employed are known to produce physiological responses[5,6]. Rats were sacrificed at 1 and 4 h after injection and hypothalamus was quickly dissected out and processed for estimation of γ-GT transpeptidase. The enzyme activity was estimated according to the method of Tate and Meister[7] as standardized by Pasha and Sadasivudu[8]. This method has been widely used to measure the enzyme activity in

choroid plexus and other areas of brain[8]. The assay mixture consisted of 80 µmol of Tris-HCl buffer (pH 9.0), 150 µmol of NaCl, 40 µmol of glycyl glycine, 5 µmol of γ-GT paranitroanilide and 0.4 ml of 2% homogenate (in 0.25 M sucrose). After 30 min incubation at 37°C the reaction was terminated by the addition of 2 ml of 10% acetic acid. After centrifugation at 5000 rpm for 20 min the absorbance of the clear supernatant was read at 410 nm. The enzyme activity was expressed as µmol of paranitroaniline liberated per gram weight of tissue per hour with reference to a standard graph plotted using different concentrations of paranitroaniline and treating it with acetic acid.

Statistical analysis was done using analysis of variance, followed by Duncan's new multiple range test.

γ-GT activity ranged from 44.14 ± 0.64 in 40-day-old to 52.96 ± 1.91 µmol *p*-nitroaniline released/g wt tissue/h in 60-day-old rats. Administration of morphine to 40-day-old rats did not modify the enzyme activity at 1 h, whereas the activity was reduced at 4 h ($P < 0.05$) after injection. In contrast, naloxone treatment produced an increase in the γ-GT activity at 1 h ($P < 0.05$) while there was no change at 4 h (Table 1). Morphine treatment to 60-day-old rats reduced hypothalamic γ-GT activity significantly both at 1 h ($P < 0.01$) and at 4 h ($P < 0.05$) after injection. Naloxone, however, caused no change in the enzyme activity either at 1 or 4 h in 60-day-old rats (Table 2).

The present results show that morphine, a natural opiate agonist and naloxone, an opiate receptor antagonist, produce changes in hypothalamic γ-GT transpeptidase activity. Though morphine sulphate failed to modify γ-GT at 1 h, it produced significant reduction at 4 h in 40-day-old rats. Administration of naloxone, on the other hand, produced an opposite effect. Earlier studies showed that glutathione content in hypothalamus reached a peak at puberty. Further, intraventricular administration of glutathione resulted in a significant increase in plasma FSH and a reduction in LH levels in ovariectomized oestrogen–progesterone primed rats[3]. Such an effect of glutathione on gonadotropin levels together with the observation of pubertal peak in glutathione content suggested an interaction of glutathione with the hypothalamic–pituitary axis. The increase in γ-GT activity in pubertal rats is consistent with the above observation. Further, it is significant in consonance with the recently held view that attenuation of opioid inhibition at the time of puberty in male and female rats is one mechanism for the onset of puberty[9,10]. Increased utilization of glutathione through γ-GT cycle maybe one mechanism for increased secretion of gonadotropins[3]. In sexually mature rats naloxone did not modify γ-GT activity, suggesting noninvolvement of glutathione utilization in endogenous opioid-mediated hormone response in these rats. Morphine sulphate had a marked inhibitory effect on hypothalamic γ-GT activity in both 40- and 60-day-old rats. Administration of morphine is reported to be inhibitory to gonadotropin secretion[5,6,11]. Available evidences suggest that glutathione utilization by the γ-GT cycle is involved in gonadotropin release[4,12]. A decrease in γ-GT activity following morphine treatment suggests that this may be one of the mechanisms of morphine-induced suppression of gonadotropin secretion. Morphine is known to regulate release of other pituitary hormones as well[5]. It may do so by altering the release of neurotransmitters at the hypothalamic level. The physiological significance of the effect of morphine on glutathione utilization through the γ-GT cycle on pituitary hormone release is not clear. The formation of γ-GT derivatives such as γ-GT dopamine may have functional significance as dopamine is known to influence release of a number of hormones from the pituitary[13–15].

Since opiates of other classes (prodynorphine and proenkephalin) are less potent in eliciting a response on gonadotropin release as compared to morphine, they were not used in the present study. However, the present results suggest that hypothalamic γ-GT transpeptidase activity is altered under the influence of morphine and reversed by opioid receptor antagonist naloxone. The exact mechanism and physiological significance of this response is yet to be understood.

The data presented suggest that opioid peptides, have an inhibitory effect on glutathione utilization through the γ-GT cycle. In pubertal rats, opioid receptor antagonist naloxone stimulated the γ-GT activity, indicating endogenous opioid-mediated suppression of glutathione utilization. This is significant with respect to onset of

Table 1. Hypothalamic γ-glutamyl transpeptidase activity in 40-day-old rats

Treatment	1 h	4 h
Saline control	44.14 ± 0.64	43.21 ± 0.8

Inhibition of biogas production by isobutyric and isovaleric acids and their precursors

M. K. Sharma* and M. M. Simlot†

Department of Biochemistry, Rajasthan College of Agriculture, Udaipur 313 001, India
*Present address: Agricultural Research Station, Mandore, Jodhpur 342 004, India
†Present address: 24 Subhashnagar, Opp. B. N. College, Udaipur 313 001, India

Isobutyric and isovaleric acids inhibit the production of biogas in the anaerobic fermentation of cowdung slurry at a concentration of 1000 ppm. Amino acids leucine and valine, whose metabolic products are isovaleric and isobutyric acids, respectively, when added to the fermenting media did inhibit the biogas production, but not to the extent free acids do, as some of the amino acids could have been utilized for protein synthesis.

METHANE gas production under anaerobic fermentation of agricultural wastes and animal wastes is a complex multistep system involving different microorganisms, which first degrade cellulose and turn the product into methane with the help of methanobacterium present in the medium[1–3]. Many investigators have reported about the importance of volatile acids in the production of methane gas from cattle wastes. Varel *et al.*[4] observed that, under conditions of optimum methane production from cattle wastes, total volatile acid is the first to accumulate in large amounts by increasing the total volatile solids in the feed. The additive effect of addition of water hyacinth[5–7] and poultry waste[8] to cowdung enhanced the volatile fatty acid content. This was further confirmed using a two-phase fermenting system[9]. Hobson and Shaw[10] reported that volatile fatty acids acetate and butyrate were not inhibitory to methane production by *Methanobacterium formicium*, but propionate was under certain conditions. Kalle and Menon[11] reported that methanogenesis was inhibited by branched-chain fatty acids like isobutyric and isovaleric acids below ambient temperature. However, Kalle *et al.*[12] reported that normal mixed cellulolytic culture produces straight-chain fatty acids, which could be due to the presence of isovaleric-degrading bacteria present in marine sediment and sewage

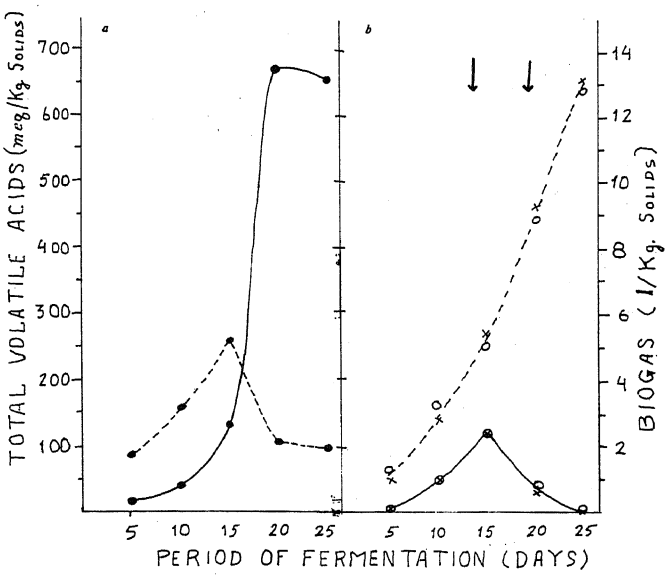

Figure 1. Effect of addition of isobutyric or isovaleric acid to the fermenting medium. Isobutyric acid (IBA) or isovaleric acid (IVA) was added on the 15th and 20th days of fermenting to a final concentration of 1000 ppm and the total amounts of volatile acids and biogas produced were measured. *a*, Control: ●----● total volatile acids; ●——● biogas produced. *b*, IBA or IVA added: O----O IVA, total volatile acids; O——O IVA, biogas produced; ×----× IBA, total volatile acids; ×——× IBA, biogas produced.

sludge[13]. Since the presence of inhibitors may also affect the rate of biogas production, the present study is directed towards the effect of branched-chain fatty acids and their precursors on biogas production.

Fresh cowdung was collected from the cattle farm of Rajasthan College of Agriculture, Udaipur. Volatile fatty acid in the fermenting media was estimated according to the method of Scarisbrick[14], by acidifying the sample with phosphoric acid to pH 2.5, diluting with equal volume of water and centrifuging to remove the solid material. Biogas production was measured by collecting the gas in an apparatus designed in this lab (Simlot, unpublished), which was connected to a digestor. The digestor contained 7.5% slurry of cowdung (total volume 400 ml) and was allowed to digest at 35 ± 2°C. The gas was collected for 5 days and measurements made every 5th day.

The production of biogas depends on the medium, temperature and other anaerobic conditions of the medium and normally begins between days 3 and 12 at 55°C in cowdung fermentation[4]. As shown in Figure 1, in this case it started after 4 days and reached the maximum production of 13.46 l/kg solid on the 20th day in the control. Thereafter, the biogas production started declining to the level of 13.22 l/kg solid on the 25th day. The amount of total volatile fatty acids rose, reaching an optimum level of 262.9 meq/kg solid on the 15th day of fermentation and then dropping suddenly to 105.8 meq/kg solid on the 20th day. These observations about sudden spurt in biogas production from 15th to 20th day and concomitant drop in the total volatile fatty acid content confirms the earlier report that biogas production is dependent on the formation of volatile fatty acids[3]. On addition of branched-chain fatty acids like isobutyric and isovaleric acids (1000 ppm each) to the fermenting medium on the 15th day, when the biogas production had started picking up, it was found that gas production had gone down considerably, while at the same time the total volatile fatty acid content, instead of coming down, had started going up. Another dose of these acids on the 20th day had totally blocked the production of biogas. These results confirm the observations of Kalle and Menon[11] regarding the inhibitory effect of these acids on methane production.

Leucine and valine through a number of intermediate steps are metabolized to isovaleric and isobutyric acids, respectively. The presence of these amino acids in the fermenting medium can be used in two ways – either for the synthesis of new proteins or enzymes, or the excess may metabolize to isobutyric and isovaleric acids. The conversion of leucine and valine to isovaleric and isobutyric acids will inhibit the methanogenesis. Table 1 gives the volume of the biogas produced when leucine or valine was added to the fermenting medium. Initially, there was not much change in the amount of biogas produced in comparison to the control. But after the 15th day, biogas production was significantly reduced as compared to the control and remained at the lower level thereafter. The total volatile fatty acid content (Table 2), however, increased significantly over the control. Thus, these results indicate that the two amino acids are partially metabolized to their corresponding fatty acids, i.e. isovaleric and isobutyric acids, respectively, with the result that biogas production is inhibited.

Production of wheat haploids through embryo rescue from wheat × maize crosses

N. S. Bains, Jaswinder Singh, Ravi* and S. S. Gosal**

Department of Plant Breeding, *Department of Genetics and **Biotechnology Centre, Punjab Agricultural University, Ludhiana 141 004, India

Appropriate hormone treatment using 2,4-D and gibberellic acid led to a high frequency (34.17%) of embryo formation in crosses of field-grown wheat strains with maize. Twenty-five days after culture on MS medium supplemented with casein (2000 mg/l) and amino acids, 30.95% of the embryos showed plant formation, 44.05% resulted in callus-like structures and the remaining failed to respond. The haploid nature of some of the regenerated plants was confirmed cytologically. Implications for wheat breeding are discussed.

WHEAT is a premier food crop of worldwide importance. It is also a crop where conventional plant breeding has paid rich dividends, as epitomized by the green revolution. However, the current impasse in yield levels calls for application of newer techniques. A major hindrance to rapid genetic turnover in self-pollinated crops, such as wheat, is the inordinately long time (generally 8–10 years) it takes to develop stable, homozygous and ready-to-use material from a fresh cross. In this context, anther/microspore culture has often been proposed as a method for producing instant homozygous lines via haploidy. In wheat, wide hybridization followed by chromosome elimination serves as an alternative route to haploidy, e.g. wheat × *Hordeum bulbosum* and wheat × *Zea mays* crosses. The wheat × *Z. mays* cross is a relatively new system which offers distinct advantages such as freedom from genotypic specificity, the bane of anther culture approach as well as the wheat × *H. bulbosum* system (which is restricted to wheat genotypes carrying the kr crossability genes). Moreover, the system is less prone to gametoclonal variation owing to the absence of a dedifferentiated phase.

Zenkteler and Nitzsche[1] were the first to report microscopic, early-stage embryos in crosses between wheat and maize. However, the frequency of embryo formation was not specified, nor was evidence presented for their hybrid origin. Intrigued by this report, Laurie and Bennett[2] set out to study early post-pollination events in wheat and maize crosses under a CIMMYT project. They demonstrated the presence of both wheat and maize chromosomes in the zygotes and observed further that maize chromosomes were eliminated during initial cell divisions. Endosperm development ceases early or never occurs and embryos fail to develop to a size that can be readily rescued. Two years later, they reported[3] the recovery of the first haploid plants using the wheat × maize system by employing *in vitro* culture of wheat spikelets, 2 days after pollination. A method that bypassed spikelet culture was devised by Suenaga and Nakajima[4], who injected 2,4-D solution (100 ppm) into the uppermost internodes of wheat stems to sustain embryo growth on the plant itself, till the appropriate stage for embryo rescue.

The present study was conducted as a preliminary assessment of the applicability of the system to indigenous material grown under field conditions and to judge its potential as a plant breeding tool. The wheat material used represented advanced, agronomically relevant homozygous lines. (For actual plant breeding purposes, however, heterozygous material would be required.) Wheat ears were emasculated 3–5 days prior to anthesis by opening up the glumes and removing the anthers, unlike the conventional practice, which involves the cutting of the glumes to expose the androecium. Freshly collected pollen from a winter maize variety, Partap 1, was used for pollinations, 3–5 days after emasculation. The pollinated tillers were administered injections of 2,4-D solution (125 ppm) into the uppermost internode, daily in the evening, for three days after pollination. On the fourth day the ears were momentarily dipped in a solution of 2,4-D (100 ppm) + gibberellic acid (75 ppm). On an average, seed-like structures (Figure 1 *a*) were seen to develop in 86.71% of the wheat ovaries pollinated with maize (Table 1). Closer examination of the ears revealed that ovaries which failed to develop into seed-like structures were damaged by severe fungal infection. The presence of a large amount of maize pollen in the floret and moisture provided by hormonal (2,4-D) ear dip might have favoured this fungal growth. Thus, seed-like structures develop in all the viable florets. Obviously, all such seeds are not the result of fertilization and are probably formed due to hormone induced enlargement. Thus, actual seed setting could be assessed only after dissecting the seed-like structures and observing the presence/absence of embryos. Twenty developing seeds each of six genotypes 15 days after pollination with maize were specifically dissected for this purpose. No visual differentiation seemed to exist between seeds that carry an embryo

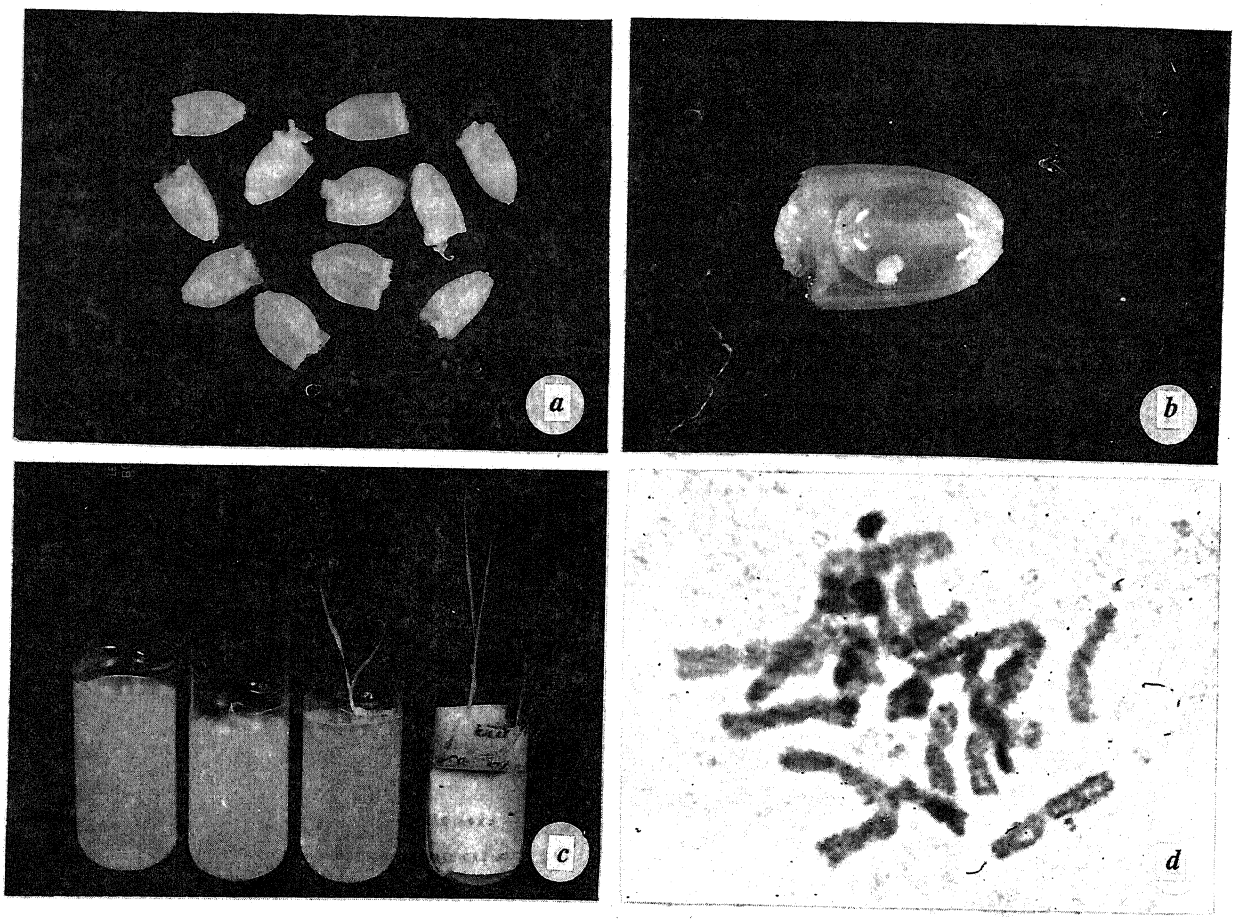

Figure 1. Wheat × maize crosses: *a*, seed-like structures observed in the crossed florets; *b*, haploid embryo floating in the watery endosperm; *c*, regeneration of haploid plants; *d*, root tip cell from embryo-derived plant showing haploid chromosome number ($2n = 21$).

and those that do not. The frequency of embryos ranged from 5 to 60% (Table 1). Small sample size makes it difficult to say whether this denotes genotypic specificity. However, remarkably high overall frequency of 34.17% indicates the scope for applying this system to plant breeding situations.

The second important factor for the success of this system is the frequency of plant emergence from the cultured embryos. For culturing, 15-day-old (days after pollination with maize) seed were surface-sterilized in 70% alcohol for 30 s followed by a 10 min treatment with 0.15% mercuric chloride and three rinses in sterile water. Embryos were excised aseptically under a stereo microscope and cultured in a medium containing MS basal salts supplemented with casein (2000 mg/l), L-glutamine (400 mg/l), L-alanine (50 mg/l), L-cysteine (20 mg/l), L-arginine (10 mg/l), L-leucine (10 mg/l), inositol (100 mg/l) and sucrose (50 g/l). The embryos were atypical in shape, having microcalli-like appearance, and were found floating in the watery endosperm (Figure 1 *b*). The cultures were incubated in total darkness for 10 days at 25 ± 1°C and then shifted to 16 h/8h light/dark regime.

The response of the embryos was recorded 25 days after the culture and is shown in Table 1. Out of the total 84 embryos cultured, 26 showed plant emergence (Figure 1 *c*), giving a frequency of 30.95% averaged over genotypes. A considerable proportion (44.05%) of the embryos formed callus-like structures probably due to the carryover effect of 2,4-D treatments. Transfer to regeneration medium in the subsequent culture can result in plant formation from these embryo-derived calli. About 25% of the embryos showed no response. Further experimentation for fine-tuning of the medium composition can greatly enhance the recovery of haploid plants.

For confirming the haploid nature of the regenerated plants, mitotic chromosome analysis of root tips was conducted. Some randomly taken plants were analysed. The roots were pretreated in a saturated solution of α-bromonaphthalene for 2 h and fixed in Carnoy's solution for 24 h. The roots were then hydrolysed in 1 N HCl at 60°C for 10 min and stained with 2% aceto-carmine. The dividing cells carried a chromosome complement of 21 chromosomes (Figure 1 *d*) in all the plants as revealed by light microscopy. The normal somatic chromosome number of hexaploid wheat is 42.

The wheat × maize system holds promise for revolutionizing wheat breeding methodology. Homozygosity is approached in one step, thereby circumventing a period of 6–8 years in the breeding cycle. This system can be very valuable for situations requiring immediate genetic amelioration, e.g. incorporation of resistance to major crop diseases. In addition, doubled haploids from crosses of divergent wheat parents is a short cut in obtaining recombinant inbreds, which are very useful for construction of genetic linkage maps using molecular markers. Haploids can also be useful for induction and recovery of mutants as well as for basic studies involving genomic relationships.

Molecular Genetics of Bacterial Pathogenesis: A Tribute to Stanley Falkow. Miller, V. L., Kaper, J. B., Portnoy, D. A. and Isberg, R. R. (eds). American Society for Microbiology, ASM Press, Washington, DC 20005, USA. 1994. XL + 529 pp. Price: £ 59.50.

This volume is meant to commemorate the 60th birthday of Stanley Falkow, who, with his enunciation of 'molecular koch's postulates', laid the foundations of molecular genetic analysis of bacterial pathogens. 'Legacy of Stanley Falkow' by Kaper and Miller brings out his extraordinary talents as a researcher matched by his exceptional skills as a teacher. In 'A look through retroscope' Falkow himself recounts the origins of his interests in bacterial pathogenicity, which started after reading *Microbe Hunters* at a very young age, and culminated in unravelling several of the molecular underpinnings of bacterial pathogenicity.

The main text of the book is divided into six parts.

Part I – 'Retrospective look at early advances' – is a historical account of how Falkow's work on extrachromosomal elements, especially R factor, increased the awareness of the scientific community that plasmids were not a curiosity of geneticists but rather had far-reaching practical implications, viz. role in bacterial pathogenesis and antibiotic resistance (Chapters 1, 2). There are reviews on the role of Tn3 in the spread of antibiotic resistance (Chapters 3, 4) and application of plasmid profile analysis to trace the epidemiology of pathogenic bacteria, which is now a burgeoning field of 'molecular epidemiology' (Chapter 5).

Colonization of the host surfaces by pathogenic bacteria represents the first and an almost indispensable step in the initiation of infectious disease process. Thus, an interest in colonization factors, both for studying the bacterial pathogenicity and for designing interventional strategies, cannot be overemphasized. Part 2 – 'Adhesins' – discusses molecular genetics of an array of colonization factors, viz. adherence factors of urinary tract pathogens (Chapter 6), *E. coli* type 1 pili (Chapter 7), pilus antigenic variation (Chapter 8) and type 4 pili (Chapter 9). These chapters not only depict the state-of-the-art of the subject but also relate the chequered path of the development of each of these areas.

Until recently, adhesins were seen as appendages passively mediating attachment of pathogens to single receptor on the host or target cells. It is, however, becoming clear that adhesins are much more complex structures in having multiple binding sites and their function is not limited to passive binding but extends to signal transduction in host/target cells. To carry out such functions adhesins mimic host molecules whose natural functions involve adherence and signal transduction. Also, co-operation exists between different adhesins in establishing an infection which is reflected in the organization and regulation of their genes. These aspects have been discussed in relation to adhesins of *Bordetella pertussis* (Chapter 10), *Haemophilus influenzae* (Chapter 11) and E-PEC (Chapter 12). Discussion on murine colonic hyperplasia, a naturally occurring disease of mice caused by *Citrobacter freundii* biotype 4280, has obvious relevance to the study of human proliferative bowel disorders (Chapter 13).

Intracellular bacteria, whether obligate or facultative, present enormous challenges to scientific and medical community. Part 3 – 'Molecular and cellular biology of intracellular bacteria' – present a detailed account of the molecular underpinnings of virulence determinants of intracellular bacteria and the cell biology of their interaction with host cells. Exhaustive genetic approaches have been used to identify *Salmonella* virulence genes. The various genes under investigation are: *spv* (*S*almonella *p*lasmid *v*irulence), *spa* (*s*urface *p*resentation of *a*ntigen), *inv* (*inv*asion), *pag* (*Pho-P a*ctivating *g*enes) (Chapter 14). Spectacular events in the host cell which accompany the invasion of *Yersinia* (Chapter 15) and *Salmonella* (Chapter 16) into the cell are also discussed.

Studies on the molecular aspects of the growth of *Legionella pneumophila* within the phagocytic cells have been presented to provide a comprehensive model by which pathogens may manipulate the host cells to suit to their intracellular lifestyle (Chapter 17). The host response to *Listeria monocytogenes*, an important food-borne pathogen, has been reviewed as a paradigm of cellular immune response to intracellular pathogens (Chapter 18). The emphasis of the review is on the cell biology of this infection, i.e. pathogen's entry into the host cell, its escape from the phagocytic vacuole using listeriolysin O (LLO) and the role of actin-driven movement in intercellular spread. The molecular genetics of chlamydial pathogenesis are currently under intensive investigation. In this context, the recently proposed chlamydial adhesins, viz. major outer membrane protein (MOMP), chlamydial cytoadhesin (CCA), Hsp-70 and another outer membrane protein (omp-2) have been reviewed. The potentialities of some of these antigens for the development of a vaccine have also been discussed (Chapter 19).

Part 4 – 'Extracellular structures and products' (Chapters 20–26) – is a critical account of the molecular genetics of the most obvious virulence determinants, viz. capsules (*E. coli* K-1 and Group B streptococci – type III), toxins (pertussis toxin and *E. coli* verotoxins), *E. coli* hemolysin, flagella (*Campylobacter* spp.) and yops (*Yersinia* spp.). Detailed information on the molecular genetics of these products has been gained primarily because these virulence factors have been most amenable to tools of molecular biology. The biosynthesis and assembly of these virulence factors have been discussed in detail. The high degree of sequence and functional conservation among dispartate virulence factors has been summarized succinctly. In these chapters, some of the very interesting topics which provide newer leads for further research are: periplasmic space of gram negative bacteria as a potential target for antimicrobial agents, study of *E. coli* hemolysin in conjunction with lipopolysaccharide to unravel its exact role in pathogenesis and tyrosine phosphatase activity of the yops of pathogenic yersiniae and their homology to eukaryotic signal transduction proteins.

Part 5 – 'Virulence gene regulation' – discusses molecular genetic mechanisms underlying regulatory loops responsible for the expression and regulation of virulence genes. The complexity of these regulatory loops has been illustrated by the well-known *bvg* regulation in *Bordetella pertussis* (Chapter 27) and methylation-dependent and *Lrp* (*L*eucine *r*esponsive regulatory *p*rotein)-dependent fimbrial gene expression in *E. coli* (Chapter 28). In addition to these, two other systems, namely urease as a potent virulence factor (Chapter 29) and plas-

mid-mediated iron transport virulence system of *Vibrio anguillarum* (Chapter 30), have been discussed. The chapter on urease makes very interesting reading wherein genetic organization and regulation of urease genes of members of enterobacteriaceae (*Proteus mirabilis*, *Klebsiella aerogenes* and *E. coli*), gram positive bacteria (*Staphylococcus saprophyticus* and a thermophilic *Bacillus* sp.) and *Helicobacter pylori* have been discussed.

Part 6 – 'Other aspects of bacterial pathogenesis' – is an assemblage of assorted aspects of bacterial pathogenicity which arose during Falkow's work detailed in the preceding chapters. None of these topics have been dealt with in previous compilations on the subject. It is apparent that these aspects of bacterial pathogenicity would constitute important areas of research in the future.

The enzyme systems responsible for sucrose transport, sucrose hydrolysis and synthesis of extracellular and intracellular polymers have been viewed as pivotal virulence factors for the cariogenic *mutans* streptococci. Newer tools which may help elucidate molecular mechanisms underlying synthesis, regulation and interrelations of these enzymes have been discussed (Chapter 31).

In general, it is very well-known that several factors, both host and pathogen, determine the minimum inoculum required to produce a disease in susceptible hosts. In this regard genetic determinants of acid resistance of *Shigella* spp. have been discussed (Chapter 32). However, the thought-provoking question in this chapter is: Are there any specific factors which dictate infective dose of a pathogen?

A great deal of progress has been made in recent years in the field of mucosal vaccines. Various aspects of the subject discussed include – cholera toxin subunit B as a model for the development of nonliving mucosal vaccines, its use as an adjuvant for other mucosal vaccines and live mucosal vaccines as carriers of heterologous antigens (Chapter 33).

The discussion on phylogenetic diversity of microbial pathogens (Chapter 34) brings into focus the bias of *in vitro* growth enrichment methods towards bacteria isolated from the environment. To what extent are these methods relevant to microbial flora of mammals? The inadequacy of these methods has been illustrated by the identification of unculturable pathogens directly from host tissue using PCR-amplified 16S rRNA sequences.

Since this volume is meant to be a tribute to Stanley Falkow, all the contributors are his former students, postdoctoral fellows or collaborators. So only those aspects of bacterial pathogenicity which have been pursued in his laboratory are reviewed. Nevertheless, it encompasses not only a good range of microbial pathogens and virulence determinants but also incorporates certain aspects, especially in Part 6, hitherto not dealt with in any of the previous works on this subject.

The book has the characteristic stamp of the American Society for Microbiology, i.e. highly authoritative and immensely readable.

All in all, this volume should form an important part of any collection, whether individual or library, dealing with bacteriology, medical microbiology, bacterial pathogenesis or infectious diseases.

Life in Moving Fluids. Steven Vogel. Princeton University Press, 41, William Street, Princeton NJ 08540, USA. 1994. 2nd edn. 467 pp. Price: $ 49.50, £ 35.

Scientists of yesteryears were known as natural philosophers: people who wondered about the workings of Nature. They appear to us as free souls, knowing no boundaries of specializations, and venturing into any body of knowledge to seek an explanation to some riddle that caught their imagination. The book *Life in Moving Fluids* by Steven Vogel is a beautiful one, one that revives the memories of the natural philosopher. It is an account of a biologist stepping out of his customary confines and thinking about the effects of flow on life in moving fluids.

Fluid mechanics has become a subject highly mathematized with a quest for exact results. The advent of high-speed computers has only enhanced this trend, and the frontier is occupied by computations of creeping flows, direct numerical simulations of turbulent flows, etc. All this is not a criticism of what goes on in fluid mechanics, but one does wonder: Is there any room for natural philosophers in fluid mechanics? Vogel's answer is an emphatic yes.

The book is structured as follows: Each chapter begins with an introduction of a set of fluid-mechanical concepts, followed by the role they play in a wide variety of biological phenomena. The discussion is clear and simple, and the speculations are intriguing. The author also describes many simple experiments done by himself. The gentle humour which he employs in his exposition is a bonus.

The book begins with the notion of a fluid and that all important property – kinematic viscosity. Here we learn how viscosity plays an important role in the lives of antarctic mammals and birds, and affects the morphology of some microcrustacean species. Then follow the very important concepts of kinematics: conservation of mass and streamlines. Based on these simple ideas one can calculate the number of capillaries in our body, even without needing the proverbial back of an envelope. The next topics are pressure and momentum. A clean derivation of Bernoulli's equation, and nice examples of flow measurements are presented. The ideas of pressure distribution and lift forces follow naturally, giving rise to beautiful examples of how these principles are 'used' by organisms to generate secondary flows, e.g. by termites to ventilate their mounds. All this leads up to a discussion of Newton's second law. It is nicely tied up with jet propulsion. It is really incredible that many living beings move by this principle, and belong to the 'jet set'!

The next few chapters drag 'drag' into focus. The new player is the Reynolds number. Here the origin of the drag force, the vagaries of the drag coefficients, separation of flow, streamlining of shapes, and scale modelling are explained in a very clear manner. Some of the author's own clean and simple experiments on scale modelling are presented. Application of the principles of drag to biological systems leads to an immediate complication since the shapes of living things are flexible and hence can interactively change with flow. Thus, there can be no discussion of 'dragginess' of a shape. All these ideas are discussed in the context of trees, microalgae, motile animals, etc.,

giving scope for some interesting questions involving evolution of shapes.

The next subject is velocity gradients, and boundary layers are introduced in a simple way laying emphasis on the geometries encountered in biological systems. Vogel captures the essence of boundary layer by saying that 'it is a place to hide from drag'. But, of course, hideouts have disadvantages too, since then there is a barrier to exchange of matter and energy. Consequently, there arise a whole lot of optimal existential problems. Thus, 'there is a price in drag to be paid versus paying in the harder currency of lift' due to their asymmetric shapes, cost of drag to be balanced against being away from the source of food, and penalty to be paid in terms of dispersal of spores for saving on drag, etc.

Then come the important concepts of vorticity, circulation and lift. Common mechanisms by which vorticity is generated are discussed followed by the topics of gliding, soaring, flying, and swimming.

The internal flows occupy the attention of the author in the next few chapters. As usual, the prototypical pipe flow is discussed. Here again the balance between power required to maintain the flow versus the decreased transport rates from wall in the absence of convection is brought to focus. Another problem faced by big organisms is the distribution of nutrient-carrying fluids to various corners of the body. This gives rise to Murray's law with its wide-ranging validity. This is fairly important given that the fraction of the metabolic rate spent on keeping the flow is considerable.

The next topic covers the low Reynolds number external flows. Here the flow is slow and the transfer rates are also low. Diffusion is the source of food, and one would have to work very hard to move in order to enhance the transport rates. Though motility is available, one is perhaps better off waiting, a fact humorously explained by the notion of 'a casual cow who, after eating, just waits for the local grass to regrow'. No discussion of creeping flows is complete without a discussion of terminal velocities. Vogel points out its relevance to survival, by citing the various structures developed by airborne particles – pollen grains, etc. – in order to maximize the dispersal distance, which has a direct bearing on fitness. The long rangedness of low Reynolds number flows is beautifully brought out by showing its relevance to information transfer by flow disturbances in the environment. The creepy games of preys and predators are subject to this feature of the creeping flows. The book ends with a discussion of unsteady flows and effects of interfaces.

Vogel intended this book to be treated, in part, as an argument that the unavoidable imperatives of mechanics of fluids underlie the biological design. He succeeds eminently in his presentation.

Here the interview of G. I. Taylor by G. K. Batchelor comes to my mind (*J. Fluid Mech.*, 1975, **70**, 625). In response to a query about the important areas in fluid mechanics, Taylor mentions the problem 'Why does a tree grow upward?'. What role did Taylor see in this problem for fluid mechanics, and, if he were alive, what would he have done regarding this or other such issues? Great minds are difficult to comprehend but it is easy enough to see that he was wondering about nature and was seeking the role of flow in nature. Taylor would certainly have given beautiful and simple resolutions of some of the issues raised in this book by Vogel.

I recommend Vogel's book to all interested in fluid mechanics. Even conventional courses on fluid mechanics can be enriched and made interesting by choosing elements from it.

Annual Review of Neurosciences 1995. W. Maxwell Cowan. Annual Reviews Inc., 4139 El Camino Way, Palo Alto, P.B. No. 10139, California 94303-0139, USA. Price: USA $ 47, elsewhere $ 52. 607 pp.

This issue of the *Annual Review of Neurosciences* covers a wide range of interests. The first article by Phillipe Soriano is on the use of embryonic stem cells for making transgenic mice. This powerful technique has been used to develop targeted mouse mutants for specific neuronal receptors. The article deals primarily with the technical advances made in this field, which have been considerable. However, for those of us interested in learning more about the contribution of targeted mice mutants to the understanding of neurobiology, the article serves more as a catalogue. A perspective on fresh neuroscientific insights obtained as a consequence of this method would have been welcome. A number of articles review the recent advances made in the understanding of various human neurobiological diseases. Of these, the article by Suter and Snipes on peripheral neuropathies, has integrated nicely knowledge from basic molecular research on the components of the myelin sheath, with information from genetic and clinical studies. The article by Warren and Ashley Jr on the fragile X syndrome sheds important light on the role of triplet repeats in causing genetic mutations. On reading this review it appears likely that the triplet repeat expansion mechanism may serve as a cause of many, as yet poorly understood, neurological disorders. A suggested role for genomic imprinting during this process makes this mechanism all the more intriguing. The review article on neurobiology of infantile autism (Ciaranello and Ciaranello) highlights the lack of understanding regarding the cause(s) of this human disease. It appears to have a genetic basis and may in some cases be associated with other neurological disorders.

A number of articles in this review have tried to put together recent experiments in understanding the development of the vertebrate central nervous system (CNS). Hatten and Heinz discuss the general principles that have emerged from studies of the development of the cerebellar cortex. This particular brain tissue serves as a good model system since it is relatively less complex and its structure is well-understood. Analysis of its development has been further aided by the presence of mutants in which parts of the cerebellar cortex do not develop properly. Colamarino and Tessier-Lavigne have reviewed the vast array of information implicating molecules in the floor plate as cues for axon guidance in the developing CNS. Many of these molecules still remain to be identified while others such as Netrin-1 and aminin are being studied extensively. Another interesting molecule is agrin, which has been shown to play an important role in the formation of the neuromuscular synapse. Bowe and

Fallon in a concise review have put together much of the new data about agrin and the proposed mechanism by which it causes clustering of acetylcholine receptors at the postsynaptic junction. Current evidence also points strongly to a role for this molecule in synapse formation in the CNS.

The article by Ranganathan, Malicki and Zuker has made a strong case for studying sensory transduction processes in *Drosophila*. The combined genetic and molecular approach, possible in this organism, has helped identify genes required at almost every step of the visual transduction pathway. As stated by the authors, while there is a great deal of similarity in the overall strategy of visual transduction between vertebrates and invertebrates, much of the underlying molecular machinery is different. Another field in which *Drosophila* molecular genetics has had an important contribution is that of circadian rhythms. In his review on the molecular neurobiology of circadian rhythms in mammals, Takahashi tells us how attempts are being made to understand the molecular basis of this behaviour using both physiological and genetic experiments. The review argues for a molecular genetic approach in mouse similar to that taken by Konopka and Benzer twenty years ago in *Drosophila*.

This issue also provides a good introduction to some new and exciting areas in neuroscience. The field of integrative processing is one such topic reviewed by Knudsen and Brainard. It looks at the two better understood stimuli – vision and audition – and their integration in the brain. Principles that emerge from the study of these two stimuli may be useful in studying other integrative processes. Another interesting new area where research is still fairly preliminary is that of plasticity in the adult sensory cortex. This has been reviewed by Weinberger. It is still too early to say what the level of plasticity is in the adult sensory cortex and the suggestion from this review is that both plastic and nonplastic populations of cells may exist. Their relative roles in adult cortical functioning await further research.

GAITI HASAN

National Centre for Biological Sciences, TIFR Centre, IISC Campus, P.O. Box 1234, Bangalore 560 012, India.

Textbook of Molecular Biology. K. Sivarama Sastry, G. Padmanaban and C. Subramanyam. Macmillan India Ltd., 2/10 Ansari Road, New Delhi 110 012. pp. i–xiii + 498. Price: Rs. 168.

Molecular biology is all pervasive in life sciences today. Although it started as a rather narrow field, the commonality of biological information and its application in living systems caused this discipline to break all barriers of specialized fields in biology so that now there is no area in biology which has not been influenced by molecular biology and which has not influenced molecular biology. Therefore, a study of molecular biology is imperative for any student of biology. Since molecular biology spans a very wide canvas, a book on this topic needs to cover a much wider area than most other subjects in biology. In this context, the book by Sastry, Padmanaban and Subramanyam is a welcome addition to the many books available in this general area. However, compared to most of the other books published in India in this area, the present book is more comprehensive and better organized. The authors have done a remarkable job in putting so many different areas together in a relatively simple narrative style which makes it easy reading for young students, to whom it is primarily addressed. Relevant topics from biochemistry, genetics, cell biology, cytology, immunology, cancer biology, genetic engineering, etc., have been amalgamated to produce this book. With so many different topics to be covered, the order of their appearance in the book can be a matter of individual choice, but as the authors point out in their preface to the book, each chapter can also be read as stand-alone since extensive cross-references to different topics help the reader navigate through related topics. Inclusion of references to more extensive books as also to articles on specific topics is very helpful.

With a constraint on the overall volume of the book (presumably to keep the price within reasonable limits), the book provides, in most cases, only the basal information on any given topic without going in for a detailed exposition. This limits the utility of the book for students at different levels of studies and for those interested in certain topics in more detail. Nevertheless, the book can be used by most students and teachers either as a primer for details in other more extensive treatises available or as a summary after having read a given topic in more detail elsewhere. In either case, the book will be useful for the student community.

This book is fairly strong in the biochemical aspects of molecular biology, as may be expected. However, factual and/or conceptual errors exist in the book, particularly in topics that relate to genetics, cell biology and developmental genetics, etc. (these are the ones that I read more carefully due to my own bias). Rather than making an exhaustive listing of these, a few examples may be noted. The $2N$ of *Drosophila melanogaster* is given as 4 instead of 8 (p. 90). The chapter on genome organization includes a brief discussion on X-inactivation in mammals (p. 111); unfortunately, however, this discussion does not make it clear that X-inactivation occurs only in somatic cells of female mammals (also the term 'lyonization' is after 'Mary Lyon' rather than 'Mary Lyons').

While discussing recombination during meiosis, the authors have also considered sister chromatid exchanges and imply that sister chromatid exchanges are central to recombination (p. 353, last para); the description gives an impression as if sister chromatid exchanges and chiasma points in meiosis are similar. While sister chromatid exchanges in mitosis and the homologous recombination during meiosis (which correlates with the cytologically visible chiasma, different from sister chromatid exchange) may share some of the enzymatic pathways, the two are distinctly separate phenomena with very different genetic consequences. In the absence of a more detailed discussion, the reader would remain misinformed on these issues.

Consideration of the genetic control of development in *Drosophila* on pp. 420–424 is rather incomplete and confusing. The classification of segmentation genes into three categories (the gap, pair rule and segment polarity genes) was proposed by Nusslein-Volhard and Wieschaus in 1980 rather than by Gehring, as the book seems to suggest (p. 421). The *fushi-tarazu* gene is not a part of the *Ant-C* complex: although it is physically included in the *Ant-C* complex DNA region, it acts independently as a pair rule gene rather than as a member of the *Ant-C* homeotic gene complex. Another common

misconception, that seems to have affected the description in this book as well, is about the term homeotic genes and homeo-box: all genes that carry the homeo-box sequence are not homeotic genes. I think the elucidation of specific details of the cascade of gene activity (beginning with the maternally acting genes and followed by the gap, pair rule, segment polarity and homeotic genes in that order) that defines the embryonic segmentation and fate determination in *Drosophila* and other higher animals has been one of the exciting hallmark achievements of the combined use of molecular biology, genetics and developmental biology. This chapter does not convey the specific information now available on this cascade of embryonic gene activity. The presentation in the book gives impression of a disjointed piecemeal information on certain genes and thus fails to carry the excitement to readers.

The chapter on genetic engineering is essentially confined to some of the basic recombinant DNA techniques (random-primed labelling deserved a place here). To justify the topic fully, it could have included examples where genetic engineering techniques have actually been employed as also the potential uses and hazards of these technologies.

While the book is generally well illustrated, the figures could be more attractive and self-sufficient: this would allow a better comprehension to the reader. This text book has made a good beginning. It is to be expected that its subsequent editions will take care of the shortcomings of the type noted above so that it evolves into a popular and authoritative textbook that is badly needed by our student community.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Opioid peptides: Two decades on

Two decades have passed since Hughes, Kosterlitz and their colleagues reported the discovery of the enkephalins from porcine brain (*Nature*, 1975, **258**, 577). These pentapeptides were the first endogeneous opioids to be discovered providing a new class of ligands to explore the physiology and pharmacology of an ever-increasing number of opiate receptors in the brain. Classically, morphine – an opium alkaloid, was the best known of the opiate receptor ligands. In the early years of opioid peptide research, much attention was focused on the possibility of developing non-addictive analgesics, a goal which proved unreachable despite enormous scientific effort. The discovery of endogeneous opioids, however, proved to be extraordinarily influential in directing attention towards neuropeptides, their role in pain perception and modulation of behaviour. Close connections were established between the brain and the gut, a fact that is not generally appreciated. While initial discoveries were made in a variety of vertebrates, very soon opioid peptides were found to be widely distributed among invertebrates, providing comparative endocrinologists with a fertile area of research. In a comprehensive review (**page 659**), Nagabhushanam *et al.* survey the occurrence and biological role of peptide opioids in invertebrates. A vast body of literature implicates these molecules in a diverse range of biological phenomena, ranging from behaviour modulation and thermoregulation to reproduction. This spectacular range of molecules and functions could hardly have been anticipated when the first reports on enkephalins appeared twenty years ago.

Of remote sensing, GIS, and the mountain goat

Wildlife biology has been one of those subjects where even the simplest questions are maddeningly difficult to answer (e.g. how many tigers are there in Nagarhole?), and the considered opinion of an expert practitioner is much more valuable than the results obtained from the most sophisticated mathematical models. Recent years, however, have seen a welcome trend of a close co-operation between the two; the availability of satellite imagery at increasingly finer scale and of powerful GIS (Geographical Information System) hardware/software has improved the situation even more. The article on **page 685** of this issue illustrates a particularly attractive contribution – of estimating the proportion of the area of the Rajaji National Park, where a population of *Nemorhaedus goral*, an endangered species of the mountain goat, can thrive.

Situated in the Dhaulkhand range in the Shivalik mountains of Uttar Pradesh, the Rajaji National Park covers an area of about 150 square kilometers. Contrary to the imagined picture of vast stretches of thick forest, the park is a rich and complex mosaic of dry deciduous forest patches, roads, human habitation, plantations, water bodies and the like. Not all of these are equally conducive for maintaining the population of mountain goats, however – they prefer areas with steep, grassy slopes and near water bodies, and tend to avoid locations close to human habitation, and those with thick shrubs.

Starting with satellite imagery down to the resolution of 36 m × 36 m, the authors were able to prepare detailed maps (2 cm = 1 km) describing the different vegetation types in the national park. To this was added the information on the location of habitations, slopes, waterbodies, etc. GIS software was then used to assign a numerical value (of index of suitability to gorals, based on what the gorals like and dislike) to each point in the map. Further analysis then showed about 35% area to be highly suitable to gorals, and 20% unsuitable to them. Clearly, such quantitative estimates would be very valuable to foresters and administrators of national parks for efficient management of wildlife.

A particularly heartening aspect of this article is the close collaboration of the different institutions – Remote Sensing Institute, the Forest Department and WWF – and one can now look forward to more of such interdisciplinary contributions based on the study of various national parks and other endangered species.

Indo-Israel Joint Programme of Cooperation

Department of Science & Technology (DST) invites applications from Indian scientists for consideration for the exchange visits to Israel in the following categories:

(a) Senior Scientists	:	For a period of two weeks.
(b) Short-term exchange	:	For scholars with a Ph D degree on an invitation from Israeli scientists, for a period of 3–4 months up to the age of 40 years.
(c) Post-doctorate	:	For one academic year (10 months) for scholars with a Ph D degree awarded not more than two years prior to the application.

Air fare to the visiting Indian scientists will be provided by the Indian side and their local hospitality will be provided by the host country.

The priority areas presently identified for the exchange visit are Advanced materials, Microelectronics, Biotechnology, Information technology and Electro-optics. Excellet applicants in other areas of material sciences and engineering will also be considered.

The scientists interested in exchange programme may send their application duly forwarded by their institution along with a two-page pre-proposal (brief justification, specific area and duration) and a brief write up on the infrastructure available at the Institution of the application.

The application may be submitted to the following address:

Indo-Israel Joint Programme of Co-operation
International Division
Department of Science & Technology
Technology Bhavan
New Mehrauli Road
New Delhi 110 016

Last date for receipt of the application for the year 1995–96 is 30th November 1995.

Ph D students, research supervisors and university research: Some observations

V. Sitaramam in his opinion 'Dynamics of the psychology of Ph D students and the question of what to do with them' (*Curr. Sci.*, 1995, **68**, 779–783) has considered only a part of the university research scenario. It is essential to look at the system as a whole. The foregoing account is based more on observations than useful statistics (which anyway is difficult to come by).

It is true that most of the research in the country (good, bad and *not so beautiful*) is carried out by research students. But they do it under the 'guidance' of their guides (research supervisors). Hence it is necessary to have a look at both these groups, Ph D students and the research supervisors, and the role their interaction plays in university research.

Students opting for Ph D can be grouped into two broad categories: (i) Those who have passed the UGC/UGC-CSIR NET (with a minimum assured standard) and (ii) Those who have not passed the same (nothing can be said about this category which may even consist of some persons having no academic merit, whatsoever).

The first category consists of two types of students: (i) those opting for Ph D because of their interest in the subject and interest in research, and (ii) those opting for a Ph D because of unemployment. The latter group is interested only in the money (the stipend), and considers Ph D programmes as employment. Students belonging to all categories get accepted for Ph D in our universities. This is because there are more unwritten laws belonging to the same category as Parkinson's fifth (?) law, which govern our university system.

One of these laws states '*Students opting for Ph D programmes can be graded on a scale of 0–10 on the basis of their intelligence/ignorance and competence/incompetence, and for every student there is a guide of the required level of competence/incompetence*'. This great miracle is possible because of another law which states '*When the authorities are interested, there is no dearth of subject experts of required degree of compliance who are ready to doctor the premature birth of anyone as a university teacher*' (a modified version of this is applicable in promotions). The Parkinson's fifth (?) law quoted by Sitaramam obviously is an extension of these two laws.

The trend of those scoring very high marks in 10th and 12th level opting for professional courses has been '*in*' for a long time. Hence the present generation of university teachers (research supervisors) is also drawn from the layers lying below the '*top-most*' layer.

The research supervisors (especially in the university set-up) can be grouped into three categories on the basis of their selection.

1. *Selection (purely) on the basis of merit.* This group consists of the best students returning from universities abroad, national institutions, from IITs, from the same university or other Indian universities. They have excellent academic records and have worked on good topics, with good guides, in good institutions. They have a good exposure, and have a deep interest in research (in specific areas). They co-operate well with the students, work hard, and publish frequently in good journals.

2. *Selection due to inbreeding.* In case of this group there is some compromise on the quality. They are better students from the same university, mostly students of those in authority. They also have a reasonably good exposure, are in general interested in research and helpful to the students.

3. *Selection due to favouritism.* In case of this group there is a heavy compromise on the quality. They have average or below average academic records. Mostly close relatives of those in authority, politicians or their friends, they have somehow managed a Ph D, have little exposure, are not much interested in research but do research because of compulsion (others are doing it, some research is necessary to justify the presence in the university environment and for promotions).

The fate of the Ph D student depends much on the guide he/she selects.

Fresh M Scs have enthusiasm. They want to do research but most of them do not know what exactly to do. They are in a state of *infatuation* with science. It is up to the guide to transform this *infatuation* into a true love for science and his/her initial interaction with science as a meaningful and long-lasting love affair. In other words, to understand that Ph D is a training programme and to guide and mould the student into a first rate researcher. Most of the research topics are suggested/selected by research guides. Fresh M Scs cannot be expected to come up with a suitable Ph D problem. No research is an end in itself. Most of them raise as many questions (if not more!) than they answer. Because of this, a guide having deep interest and

working constantly in any field will have enough problems for fresh students.

Now the question arises: 'What can be done to improve the situation?' Three things can be done:

1. The selection of the university teachers can be made more rigorous, if possible at the national level, than relying on local selection committees.

2. The UGC/UGC-CSIR NET can be modified with more emphasis on research aptitude, and

3. Universities can introduce entrance test for those who have not passed UGC/UGC-CSIR NET/GRE/GATE etc. for registering for a Ph D.

About the dynamics of the psychology of research students, I am aware of one. All students start their Ph D programme with an intention (hope!) of completing it in 3–4 years. Some of them who have teamed up with *not too enterprising* guides take very long (7–8 years). It takes 2–3 years for the student to realize that the guide is not very helpful. The student continues because he/she feels that in another 1–2 years the work can be completed. And it is better to spend a little more time than losing the efforts already put in for 2–3 years. After another year if the situation still remains the same, the student continues. As time passes, the time required to complete Ph D becomes increasingly a lower fraction of the time already spent. There are societal compulsions also (of relatives and friends scorning 'he/she is not intelligent enough to get a Ph D'). The end of this prolonged (perennial) suffering is when both the student and the guide get totally fed-up, and the guide decides to resort to the Parkinson's fifth (?) law. This leaves an incompetent guide with one more feather in his/her cap (of having produced one more Ph D) and a student who has lost all interest in research (possibly some interest in life also), overaged with a Ph D degree which at present does not have a ready market.

Finally, I would like to disagree with Sitaramam in his suggestion that we should plan our programmes on the basis of the average performers. In my opinion we must strive for excellence and excellence alone. Planning on the basis of average performer results in compromise. Compromises make more compromises necessary. And all these compromises spoil the system.

SCIENTIFIC CORRESPONDENCE

Recent finds of ancient gold mining sites in south Uttar Pradesh

A prominent ancient gold mining site was recently discovered by the authors[1] in the Precambrian Shield region of Uttar Pradesh. It is located about 2.5 km west of Gurmura village in Sonbhadra district (Figure 1). The clusters of old workings are spread over an area about one km in strike length and over 600 m wide. It can be divided into northern, central and southern parts. The northern part shows seven elliptical to rectangular trenches measuring up to 30 m × 10 m × 10 m in size with an incline aimed to exploit easterly plunging ore body. The main hillock, locally referred to as Sona Pahari, forms the central part of the area of old workings. It has large trenches, the largest being about 60 m × 10 m × 10 m located on top of the Sona Pahari. The southern part extends over a length of about 500 m. This has two main trenches. The larger measures about 30 m × 5 m in plan. Both the trenches have inclines. Mishra[2] had speculated about the possibility of gold mining at Sona Pahari (golden hillock) on phonetic connotation and also on the basis of its location in the provenance of Ashokan rock edicts, which are strikingly common in gold-bearing regions of India.

Regionally, the early to middle Proterozoic rocks of southern UP, correlated with the Bijawar[3] Group, rest over a granitic basement, viz. the Dudhi Granitoid exposed to the south, and are overlain by late Proterozoic Vindhyan sediments exposed to the north (Figure 1). The area exposes a dominantly argillitic sequence with minor graywacke–arenite intercalations referred to as the Parsoi Formation[4] of Bijawar Group. The argillites show E–W to ENE–WSW-trending foliation with high dips generally towards south. The succession of metamorphosed chemogenic sediments comprises banded hematite quartzite/jasper, banded magnetite quartzite; argillite sequence consisting of phyllite–graywacke–arenite units and the associated volcanics consisting of a suite of basic to ultra-basic phases, agglomerates and tuffs. The Group compares well with the Precambrian Greenstone Belts[5]. The argillite sequence is intruded by a number of quartz veins with sympathetic trend emplaced probably synchronous to the emplacement of a granitic pulse, viz. the Jhirgadandi granite, in the adjacent area. The mineralized quartz veins are oxidized on the surface and exhibit pyrite, arsenopyrite and galena. Narrow zones of wall rock alteration, indicating carbonatization and kaolinization, signify hydrothermal action. The mineralization appears to be controlled by E–W to ENE–WSW-trending folds and the ancient miners seem to have excavated the richest portion of ore emplaced along the axial-plane shears of the doubly plunging folds with plunge around 35°.

The analytical results for the major trace elemental contents of 50 surface grab samples collected from the area indicate the presence of gold and silver along with other associated metallic elements. Forty-three per cent of samples analysed by Atomic Absorption unit at chemical laboratories, Geological Survey of India at Lucknow, Hyderabad

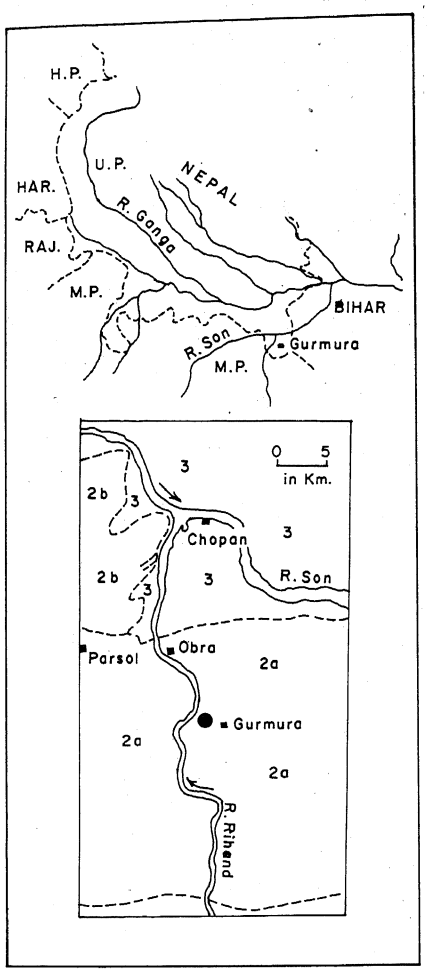

Figure 1. Geological map and location of ancient mining sites around Gurmura, Sonbhadra District, UP. Index: 3 – Vindhyan Super Group; 2b – Agori Formation; 2a – Parsoi Formation; 1 – Dudhi Granitoid; 0 – Location of old workings.

and Calcutta, indicated anomalous gold analysing from 0.10–2.80 ppm Au with 5–55 ppm Ag, 35–535 ppb Hg, up to 0.34% Cu and 0.12% Zn, 200–3000 ppm As, average 1.9% Pb and up to 20 ppm Cd (analysed in one sample). About 95% of anomalous values are from quartz vein samples and 5% are from argillite lithology. The anomaly distribution is shown in Table 1.

Table 1.

Lithology	Anomaly (%)	Au range (in ppm)	As range (in ppm)	Arithmatic mean for Au (in ppm)
Quartz vein	95	0.10–2.80	200–3000	0.83
Phyllite	5	0.16	n.d.	0.16

Preliminary limited analytical data indicate the presence of Au, Ag, Cd, Pb, Cu and Zn. The favourable geological set-up for mineralization and the associated extensive old workings make it a new prospect. Detailed geochemical sampling, presently in progress, is likely to reveal the exact nature of mineralization.

A noteworthy find includes the presence of a large number of crude stone crushers and mortars scattered throughout the area. The stone mortars have elliptical depressions measuring 20 cm × 15 cm in plan and are mainly of hard arenitic or doleritic rocks. The find suggests that grinding was an important stage in winning or concentrating the ore. The gold was extracted in a phased manner. Evidences of ancient gold mining and extraction in similar manner along with similar stone crushers and mortars have also been recorded from the contiguous western area around Sudda[6], Sonkorwa, Matehni and Gurhar Pahar[7], etc., situated in the Sonbhadra District, UP, and Sidhi district, MP. The absence of slag material, retorts, etc., associated with smelting of base metals, indicates that the base metals have not been extracted and all the mining activity was for gold only.

As regards the age of the ancient mining activity, the preponderance of stone crushers and mortars with occasional finds of iron chiesels, etc., point to ancient historical period. The age of gold mining is pre-Mauryan and might be pre 2400 BC.

Parasitism of muscardine fungi on *Meloidogyne incognita* eggs

Root-knot nematode, *Meloidogyne incognita* (Kofoid and White) Chitwood, is a serious pest in vegetable and pulse crops in India[1]. Several biocontrol agents have been reported on root-knot nematodes the world over. Some of the bioagents are found very useful in managing the nematode problem in agricultural crops[2]. Hence, in this context, two important entomopathogenic muscardine fungi, *Metarhizium anisopliae* (Metch.) Sorokin and *Beauveria brongniartii* (Sacc.) Petch, commonly used for the management of root grubs, cutworms and termites, were tested for their pathogenicity against eggs of *M. incognita* in the laboratory.

The fungi were tested against fresh eggs obtained[3] from egg masses collected from infested roots of tomato following petri dish bioassay technique[4]. Spores of respective fungi were sprayed on 2% water agar plates at the rate of 10^7 conidia/plate; each plate was previously charged with 25 eggs of the nematodes. In control plates, only sterile distilled water was sprayed. Treatments were replicated four times using completely randomized design. Plates were incubated at 27 ± 1°C and fungal

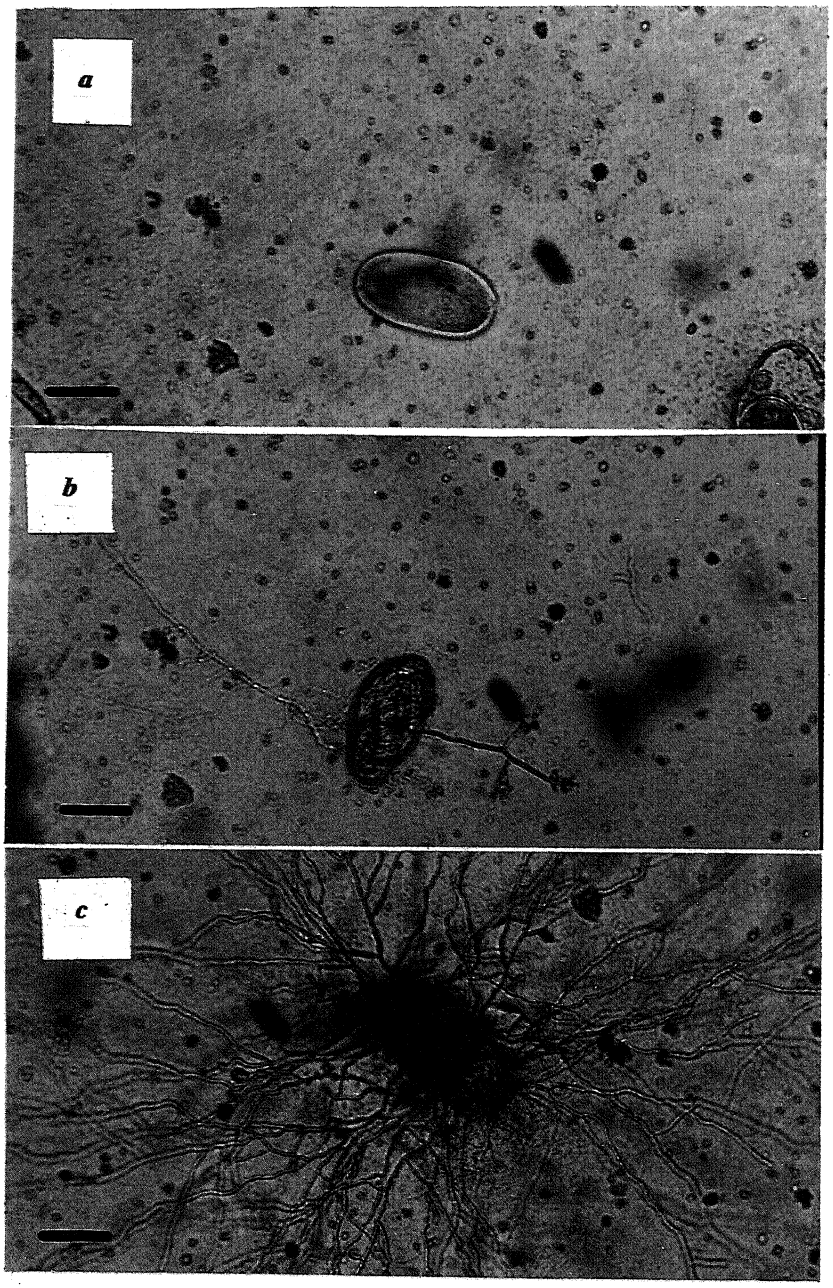

Figure 1 *a–c.* Parasitism of *M. incognita* eggs by entomopathogenic muscardine fungi (bar = 25 µm). *a*, Healthy egg of *M. incognita*; *b.* Egg parasitized by *Beauveria brongniartii*; *c.* Egg parasitized by *Metarhizium anisopliae.*

proliferation and colonization of nematodes eggs were recorded at 48 h intervals for two weeks. Hatching of larvae from eggs was also recorded from treated as well as control plates. Fungus-induced mortality in the eggs was confirmed under research microscope.

Results of plate assay clearly showed that both muscardine fungi have parasitized *M. incognita* eggs (Figure 1). *M. anisopliae* caused mortality in eggs ranging from 28.0 to 32.0%, with an average of $29.3 \pm 2.3\%$, while *B. brongniartii* caused 28.0 to 48.0% mortality in eggs, with an average of $38.7 \pm 2.0\%$. The average egg hatching in *M. anisopliae* and *B. brongniartii* treated sets was 56.0 ± 4.0 and $42.6 \pm 4.6\%$, respectively. A negative impact on egg hatching was observed due to fungus parasitism in treated sets compared to untreated control sets, where average $88.0 \pm 4.0\%$ normal hatching was recorded. This is the first report of *M. anisopliae* and *B. brongniartii* pathogenicity against root-knot nematode eggs in India. However, very recently, the pathogenicity of *Beauveria bassiana* has been reported against *M. incognita* from India[5].

Therefore, this study indicates that muscardine fungi, which are beneficial for management of soil insect pests, can also simultaneously be used for management of root-knot nematodes attacking agricultural crops. A complex of pest attack is very common in sandy loam type of soils, e.g. attack of white grub and *M. javanica* on groundnut and cutworms and *Meloidogyne* spp. on potato and tobacco in Gujarat. Further studies with these fungi on complex of nematode and insect under field conditions are warranted.

Intellectual property rights and biological resources: Specifying geographical origins and prior knowledge of uses

Madhav Gadgil and Preston Devasia

Intellectual property rights

Humans put to use a tremendously wide variety of other living organisms. Given the modern understanding and capabilities of manipulation of genetic material, this range now potentially encompasses all of living organisms. This has prompted an interest in claiming intellectual property rights (IPRs) over knowledge pertaining to uses of living organisms—not only novel organisms created through genetic manipulation, but even those merely isolated from nature. IPRs are also claimed over a variety of products of living organisms modified through human agency to varying degrees[1].

Living organisms have of course been genetically modified for millennia by farmers selecting seeds. A variety of biological products have also been used in applications ranging over cosmetics and pesticides to drugs. While such usage and knowledge may have been kept limited amongst certain clans or communities in the past, formal claims of IPRs are a recent development. In 1873 Louis Pasteur was awarded a patent on a yeast culture. Subsequently, many patents have been awarded on 'non-naturally occurring compositions of matter' based on living organisms designed for a variety of uses such as drugs and pesticides. Seeds began to receive patent-like protection in 1930s in the US and a genetically modified organism, a synthetic, plasmid injected *Pseudomonas* capable of degrading crude oil was awarded a US patent in 1980. In agreeing to the award of this patent, the US Supreme Court remarked that the US congress intended the statutory subject matter of the Patent Act to 'include anything under the sun that is made by man'. By now IPRs in the US extend to plasmids, vectors, cell lines, microorganisms isolated from nature, strains of cultivated plants and man-made animal forms such as polyploid oysters and transgenic mice[2]. Other countries are beginning to follow suit, and a greater and greater range of materials derived from living organisms, processes involving living organisms as well as self-reproducing living entities are now subject to IPRs.

The General Agreement on Trade and Tariff (GATT) aiming to reduce distortions and impediments to international trade includes an agreement on Trade-Related aspects of Intellectual Property Rights (TRIPS). TRIPS addresses itself to the issue of IPRs over living organisms and products and processes derived from them. It stipulates that members must accept patenting of microorganisms and microbiological processes, as well as protection of plant varieties either by patents or by an effective *sui generis* system or by any combination thereof. TRIPS presently permits members to exclude from protection plants (other than plant varieties) and animals and essentially biological processes for the production of plants and animals[3]. It is however likely that protection would be extended to these areas as well when GATT next comes up for review in 1999.

Convention on biological diversity

Concern for access to living resources, and their conservation has grown hand in hand with the rapidly expanding scope for use of living organisms towards human ends. These concerns led to the Convention on Biological Diversity (CBD) that came into force in December 1993, and has a current membership exceeding 125 countries. CBD aims to promote conservation of biological diversity, sustainable use of its components and equitable sharing of the resultant benefits. Till CBD living organisms were considered a common heritage of the humankind, this convention accepts them as a sovereign property of the nation states[4]. But living organisms are widely distributed over the world especially so since 1500 AD with rapid development of transoceanic transport. CBD therefore specifically recognizes 'countries of origin' of living resources and agrees to certain special treatment to such countries of origin, in particular those that belong to the categories of developing countries and small island states. All member countries of CBD agree to facilitate access to biological resources of which they are sovereign owners. In return the Convention promises developing countries of origin of such resources preference in location of research and development activities, favourable terms for transfer of technology and assistance towards development of technological capabilities. It promises such treatment not only on behalf of national governments, but private enterprises as well. It of course stipulates that this shall be on mutually agreed terms and in consonance with the IPR agreements (Articles 16 and 18, Convention on Biological Diversity[4]).

CBD not only recognizes special claims of developing countries of origin of living resources, but recognizes the role of indigenous communities also, in particular their womenfolk in conservation and sustainable utilization. It calls for a recognition of their conservation practices and their knowledge of manifold uses of living resources and stresses the need for equitable sharing of benefits of utilization of these resources with the indigenous communities (Article 8j, Convention on Biological Diversity[4]).

Two approaches

GATT (including TRIPS) and CBD thus represent two significant and separate approaches to the utilization of living resources of the earth to human ends. GATT aims to promote global economic growth by removing impediments to international trade. TRIPS aims to promote such economic growth through fostering technological innovation by guaranteeing on a uniform, international basis some degree of exclusivity to inventors on their inventions in order to be assured of a reasonable profit and to justify risks of development. CBD would also contribute to such global economic growth by

facilitating access to living resources. But CBD equally focuses on conservation and sustainable use, coupled to equitable sharing of benefits of such use. In its attempts to promote conservation, Article 22 of CBD stipulates that the obligations of the contracting parties under the convention are to take precedence over their obligations arising from other international agreements where the latter obligations would cause serious damage or a threat to biological diversity. In its attempts to create a stake for developing countries in conservation of biodiversity CBD stresses the need to share with them benefits of use of living resources, including the need to share development of and transfer of technology. These provisions have been criticized, in particular by US representatives as a serious interference with the intellectual property principles embodied in TRIPS and GATT. It was primarily on these grounds that the US has remained outside CBD, although almost all other major industrial and developing countries have joined it[5].

Development and conservation

In the emerging world order it is now necessary to flesh out the provisions of CBD to clarify their relationship with IPR-related regulations and to promote CBD's vital objective of long term conservation of biological diversity. The CBD provisions in this context attempt to create a stake in conservation of biodiversity for biodiversity-rich developing countries and indigenous communities of such countries living close to the natural world. CBD acknowledges that development to alleviate poverty is necessarily a high priority for these countries and communities. Biodiversity conservation would therefore involve serious opportunity costs for them, for which they must be compensated in order to motivate them to participate in conservation efforts. The precise mechanisms to achieve this must now be worked out.

Need for recognition

Such an effort would require as a first step appropriate recognition of countries of origin of specific elements of biodiversity, and of pertinent knowledge and conservation efforts of indigenous communities. While the details of transfer of financial resources and technology that such an effort would entail are likely to be controversial, the desirability of according due recognition to the countries of origin and indigenous communities should be a universally acceptable proposition.

As of today, there are no formal mechanisms to accord such recognition to countries of origin of genetic resources, or to the indigenous communities for their knowledge and practices of sustainable use. CBD visualizes all member countries organizing an effort at inventorying and monitoring biodiversity and developing appropriate information systems. This is however a massive undertaking and would take considerable time, more so because many diversity-rich developing countries have inadequate scientific and technical capabilities to undertake such an exercise. Such an exercise may also leave out of its ambit documentation of knowledge and practices of sustainable use of various elements of biodiversity by indigenous communities. It is therefore necessary to work out additional mechanisms of awarding such recognition to countries of origin and to indigenous communities.

Patent specifications

We suggest that appropriate augmentation of the requirements for the specification accompanying applications for patents and other IPR protection would be one such very useful mechanism. The four universally accepted requirements for the patentability of any invention include: novelty, nonobviousness, usefulness and adequate specification. Every patent application must disclose details of the invention with the help of a patent specification that describes an invention in sufficient detail to: (a) allow the patent office, and other interested parties to assess its claims of novelty, nonobviousness and usefulness; and (b) allow a person skilled in the art to reproduce it. Such a specification or disclosure statement has to accompany, or shortly follow a patent application[2,6]. Patent legislation has historically developed in relation to mechanical and chemical innovations. The specification requirements for innovations involving the use of biological materials are therefore only now beginning to evolve, primarily through judicial interpretations. Such interpretations have resulted in the requirement of deposition of the appropriate living material in an internationally recognized repository such as the Fermentation Research Institute of Japan or the European Collection of Animal Cell Cultures in the United Kingdom[2]. But there is no clearcut understanding today that the specification must include fuller details regarding the biological material such as the country of origin. Nor is there so far any formal acknowledgement of the need to accord recognition to community-based knowledge. However, many patent specifications do voluntarily provide such information. Thus European Patent 0010061 A1 800416 concerning novel pharmaceutical preparations containing an extract of the mollusc *Perna canaliculus* states it to be found on the shores of New Zealand[7]. In the case of American Patent 05298251 (1992) regarding fungicides derived from neem oil there is a mention of prior knowledge of communities regarding its uses[8].

Evidently, a further, quite marginal increase in the formal requirements of the specification would admirably serve the purpose of according recognition to the countries of origin and indigenous communities involved in sustainable use of the concerned biological resources. The proposed requirement should not only cover inventions which result in living material, such as a microorganism isolated in a culture, seed of a variety of cultivated plant, or a transgenic animal. It should also cover other products dependent on biological sources, such as alkaloids derived from plants and used as therapeutic agents or pesticides. Furthermore, the requirement should also extend to products that are essentially derived from biological sources, for instance, a synthetic molecule that differs a little from but has the same aroma as sandal (*Santalum album*) and was inspired by it. In all these cases, the specification should include a clear mention of the biological source material, the known country or countries of origin of that material, and all known information pertaining to knowledge and practices of sustainable use of that biological source material by indigenous communities in the country or countries of origin. In this context, it is essential to clarify the meaning of the term country or countries of origin. We suggest that the country/countries of origin be defined as those countries in which the biological material is known to have occurred as components

of natural biological communities, or under cultivation/domestication prior to the modern age of global transport beginning 1500 AD.

Geographical distribution

Ascription of a country or countries of origin to any genetic resource is evidently related to the patterns of geographical distribution of living organisms. Certain groups of organisms are apparently ubiquitous in their distribution. This is likely to be the case with spore-forming microorganisms. Thus most species of the slime mould genus *Dictyostelium* range over all continents and from tropics to arctics[9]. However, such wide ranging species are likely to harbour considerable intraspecific genetic variation within their populations. It is therefore possible that specific genetic variants may be confined to one or few countries of origin. Other microorganisms commensalic with higher plants or animals may have more restricted distributions. Thus the ectomycorrhiza *Tricholoma marsutaki* is known only from the host *Pinus densiflora* in certain specific habitats in Japan[10]. A few higher organisms are ubiquitous, but most have distributions limited to one or few countries or had such distributions prior to the suggested cut off date of 1500 AD. Many species of even highly mobile organisms like birds are endemic to just one country. Thus of 969 species of Indian birds, 69 are endemic, while of a total of 1519 species of Indonesian birds as many as 258 occur in no other country. Levels of endemism are higher in other, less mobile groups of organisms. Thus of 206 Indian species of amphibians as many as 110 are endemic, and of 270 Indonesian species, fully 100 are endemic[11].

Multiple lineages

The question of country of origin would also be complicated in case of organisms produced through human intervention from multiple lineages. Thus the high-yielding rice variety IR 64 produced at the International Rice Research Institute in Philippines is based on genes from 20 landraces coming from eight different countries namely China, India, Indonesia, Korea, Philippines, Thailand, USA and Vietnam[12]. The situation is apt to become even more complex in days to come. Already there exist transgenic organisms like *Nicotiana tabacum* with an endotoxin-producing gene from *Bacillus thuringiensis*[13]. *N. tabacum* may be assigned to several tropical American countries as countries of origin, but *B. thuringiensis* has a worldwide distribution. How to deal with issues of geographical origin of such transgenics clearly calls for further thinking.

Public scrutiny

Specifications accompanying patent or other IPR applications are open to public to varying degrees and after varying intervals following the filing of an application. It is suggested that this part of the specification relating to the biological source, country/countries of origin and knowledge and practices of sustainable use by indigenous communities be open to full pubic scrutiny immediately after the filing of the IPR application. This would permit countries with possible claims as countries of origin, and as repositories of public knowledge and practices of sustainable use to examine the patent applications and make any submissions that they may wish to make. It would also permit other parties, such as NGOs interested in furthering the interests of indigenous communities to make such submissions.

Inclusion in CBD and TRIPS

Inclusion of such specification in the patent application of course does not commit the inventor or others working the innovation to share the benefits arising therefrom in any way. That would obviously remain a matter of further negotiation. However, the specification would immediately help motivate potential country/countries of origin to document their own biological resources and to participate in *in situ* conservation efforts. It would also promote efforts to document and help perpetrate knowledge and practices of sustainable use by indigenous communities. Both these are important objectives of the CBD, with very broad-based acceptance at the international level. We therefore suggest that such specification should be accepted not only as an elaboration of CBD by all countries party to it, but also be made a part of the TRIPS under the GATT.

Developments and trends in inductively coupled plasma mass spectrometry and its influence on the recent advances in trace element analysis

V. Balaram

A brief introduction to the various instrumental methods such as atomic absorption spectrometry, X-ray fluorescence spectrometry, neutron activation analysis, inductively coupled plasma atomic emission spectrometry, thermal ionization mass spectrometry, etc. are presented highlighting their relative merits and demerits. The history and developments of inductively coupled plasma mass spectrometry (ICP–MS) and its advantages and limitations over other multi-element instrumental techniques are reviewed. Extended capabilities by hyphenating ICP–MS to various other well-known sample introduction techniques such as flow-injection, electrothermal vapourization, chromatographic methods and laser ablation are discussed in brief. The recent development of high resolution multi-collector double-focusing magnetic mass spectrometer with inductively coupled plasma at atmospheric pressure as source is also discussed. Some of the areas where more developments can be expected in future are suggested.

RECENT developments in basic material research, environmental studies, quality control protocols in most industries, etc., have placed new demands on the field of metal analysis. Detection and accurate estimation of almost all the elements in the periodic table at ng/ml or μg/ml range has become an important requirement in the fields of both basic and applied research[1–4]. For example, in the environmental analysis field, the number of regulated elements is becoming more and more and the required levels are moving down to lower levels. Regulations that are being established by many countries for the inorganic contaminants in water and food-related materials, the increased awareness of the importance of trace elements in foods and the element speciation have created demands mainly for increased sample throughput and for lower levels of detection. Earth scientists working on geochemical problems need to determine relative and absolute abundance of the elements present even at trace and ultra-trace levels in a variety of rocks and minerals, with the object of discovering principles governing their distribution and migration[5]. Precise estimation of isotope ratios of certain elements such as Sm, Nd, Pb, U, etc., at very low concentrations is important for applications such as radiogenic dating of rocks, ore deposits and in very accurate estimation of certain elements by isotope dilution method. There is also a need to characterize a variety of materials for trace metal impurities in several industries. The semiconductor industry, for example, requires determination of several trace elements in pure materials. As the density of the circuitry increases and the geometry shrinks, the need for pure and purer materials increases. The R&D laboratories at the chip manufacturers are working on the needs of one or two generations into the future because the pace of development accelerates so fast. Most of the other industries need their finished products to be analysed for the presence of trace metal impurities. For example, analysis of trace elements in copper is of great significance in electronic industry, where properties of copper may be severely affected by the metal contaminants at levels even below part per million concentrations (μg/g). The need for purer and purer reagents for the R&D laboratories, very often requires checking of the common mineral acids and other laboratory reagents for the contamination by certain elements at ultra-trace levels (for example, Rb, Sr, Sm, Nd, Pb, U, etc., for geochronological studies). Finally, the role of trace elements in human health and disease[6] is an area of immense interest for it is known that over a quarter of elements in the periodic table are essential to life. Thus, highly precise and accurate estimation of several elements at very low concentrations is required in a variety of fields such as geological, industrial, nuclear, environmental and biomedical. Most often, the sample volumes are relatively small and analytical requirements relatively high requiring very highly sensitive instrumental techniques for their analysis.

V. Balaram is in the National Geophysical Research Institute, Hyderabad 500 007, India.

Methods for the analysis of elements

From the turn of this century there has been an analytical revolution with succession of a series of analytical

instruments with multielement capabilities. The dominant instrumental analytical techniques available currently for qualitative identification and quantitative estimation of most elements in the periodic table include atomic absorption spectrometry (both flame and graphic furnace AAS), X-ray fluorescence spectrometry (XRF), neutron activation analysis (both instrumental and radioanalytical NAA), thermal ionization mass spectrometry (TIMS), spark source mass spectrometry (SSMS) and inductively coupled plasma atomic emission spectrometry (ICP–AES). Most of these are capable of carrying out rapid multielement analysis at μg/ml levels, except for AAS which can detect and determine one element at a time. Other disadvantages of AAS (both flame and flameless) include the limited concentration range (requiring multiple dilutions to get a signal of appropriate intensity on scale) and the sequential nature of most systems. The fact that only one or two elements can be determined at a time is the major reason which caused its decline in favour of ICP–AES, which was made available in the mid-1970s. Though ICP–AES provides multielement detection for most elements at sub μg/ml level, there are numerous limitations resulting from complex spectra and matrix interferences. XRF which started in the mid-1950s is a popular analytical technique in both research and industry for the estimation of major and minor elements in several matrices such as rocks, alloys, etc. This technique suffers from drawbacks such as, interferences, very high detection limits for several trace elements in the above matrices, and also this technique cannot handle solutions. One of the main strands of analytical advancement was the development of neutron activation analysis (NAA). Although the principles of NAA had been understood since the publication of Hevesy and Levi's[7] work in 1936, the full potential of the technique was realized only during the 1960s after the development of high resolution gamma-ray detectors[8]. It is a nondestructive technique and offers multielement capability, together with relatively good levels of sensitivity (μg/ml levels). The need for a nearby reactor often precludes the consideration of NAA. If such a facility exists, the technique can be valuable. However, a greater disadvantage of NAA is the production of radioactive waste apart from having matrix interference effects. However, the radiochemical separation (RNAA) overcomes many matrix interference problems and offers low detection limits (sub ng/ml levels). But it involves many long drawn separation procedures which may carry the potential of delivering a high dose of radiation to the analyst. Thermal ionization mass spectrometry (TIMS) is a well-established method for measuring both radiogenic and nonradiogenic isotope ratios. Isotope ratio measurement of elements such as neodymium and strontium is routinely accomplished to high levels of precision and accuracy. But certain elements cannot be analysed by this technique as the efficiency of thermal ionization decreases with increase in their ionization potentials. Further disadvantages of thermal ionization include, the extensive sample preparation and prolonged analysis times. TIMS is also applicable to elemental analysis. Very high precisions are attainable using the isotope dilution method, though this is limited to elements with more than one naturally occurring isotope. Though in recent years multicollector systems for parallel collection of several isotopes have been perfected, and offer enhanced efficiency and drift compensation, TIMS is not suited to the routine analysis of samples in large numbers.

During the last 15 years, considerable attention has been paid to the development of yet another and more powerful analytical tool called inductively coupled plasma mass spectrometry (ICP–MS) by the combination of plasma ion source with mass spectrometry techniques, which has revolutionized elemental analysis and has become widely accepted as a powerful tool for trace and ultratrace elemental and isotopic analysis. Thus, evolution of instrumentation continues with the latest method being ICP–MS.

History and development of ICP–MS

Gray[9] was the first to demonstrate the potential of the plasma source mass spectrometry in 1975. He used a direct coupled plasma (DCP) and showed that strong signals could be obtained with low-background levels, so that detection of elements in μg/ml region was possible in aqueous solutions. Although these results were encouraging initially, they also revealed the limitations of the DC plasma used. The gas temperature of about 3500 K was too low to provide adequate sample volatilization, dissociation and ionization of the elements, especially those with ionization energies above 8 eV. Microwave-induced plasma (MIP) was also rejected on the basis of its low-gas temperature and ICP was considered the most suitable. These historic observations by Gray followed by the pioneering work[10–14] by him at the University of Surrey along with Alan Date, at British Geological Survey, UK; R. S. Houk, from Iowa State University at Ames, USA and Don Douglas, at Sciex, Canada in the subsequent years have brought about the development of this powerful analytical instrument. The major innovation in the design of ICP–MS is the interface between the ICP and the quadrupole mass spectrometer. Here, ions produced in the plasma at atmospheric pressure are transported into the quadrupole mass analyser held under ultra-high vacuum through a differentially pumped vacuum system which is not technically simple. The first commercial instruments were introduced in 1983 by two firms, namely V.G. Isotopes (now FI Elemental Analysis, UK) and Sciex Inc. (now Sciex–Perkin Elmer, USA). Perhaps a reflection of the success

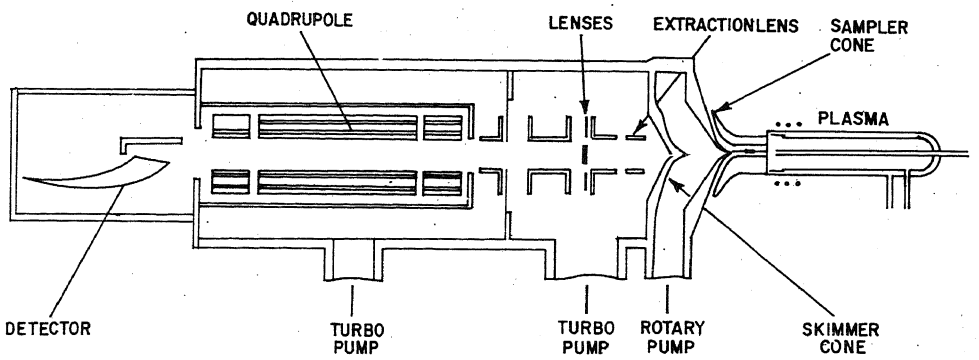

Figure 1. A schematic of plasmaquad system.

is that more than ten firms are manufacturing and marketing this particular instrument world-wide today. Efforts are also on at BARC[15], Bombay in India to produce this instrument indigenously. Though there are several hundreds of instruments installed in chemical laboratories all over the world, there are only two ICP–MS instruments in India at present. One instrument (Elan 250, Sciex, Canada) is at the Indira Gandhi Centre for Atomic Research, Kalpakkam and the other (VG Plasmaquad, FI Elemental, UK) at the National Geophysical Research Institute, Hyderabad. Though these two instruments were procured mainly for the analysis of nuclear and geological samples respectively, they have also been continuously utilized by several other groups in the country working on a range of disciplines such as geochemical, environmental, water, biological and metallurgical fields since the last eight years.

Over the last decade, ICP–MS has been well established as a powerful tool for simultaneous multielement analysis. The low detection limits, high sample throughput, small sample quantities required for analysis, element versatility (major, minor, trace and ultra-trace) and isotopic capabilities are some of the important features which have made ICP–MS an excellent spectroscopic technique for the analysis of a variety of materials.

System outline and the principle

Configuration[16] of the instrument consists of three basic units: i) a conventional argon ICP operating at temperatures of 6000–9000 K with a nebulizer, spray-chamber, work coil and associated power supplies, ii) a conventional quadrupole mass spectrometer and associated data collection electronics, which permit rapid scanning of the selected mass range between 0 and 300 amu (atomic mass units), and iii) an interface unit consisting of two water-cooled nickel cones, each containing a small orifice at the centre, which allow sampling of the plasma gases and transfer of the ion-beam into the mass spectrometer.

The principle of ICP–MS can be understood with reference to the schematic diagram given in Figure 1. Samples in the form of solution are introduced through the peristaltic pump at a rate of about 1 ml/min into the central region of the plasma at atmospheric pressure with the help of a nebulizer and a water-cooled spray-chamber system. The sample is heated to a temperature of approximately 9000 K in the plasma, resulting in a series of processes involving desolvation, vaporization, dissociation, atomization and ionization[17] (Figure 2) in the 'analytical zone' of the ICP. At this temperature, chemical interference effects are insignificant, and essentially all atoms are ionized to a very large extent (majority of the elements in the periodic table are expected to ionize to the extent of about 90% in ICP). The efficiency of ionization in the argon plasma as calculated by the Saha equation[18] shows that the formation of singly charged ions is very efficient in argon plasma and over 54 elements are expected to be ionized with an

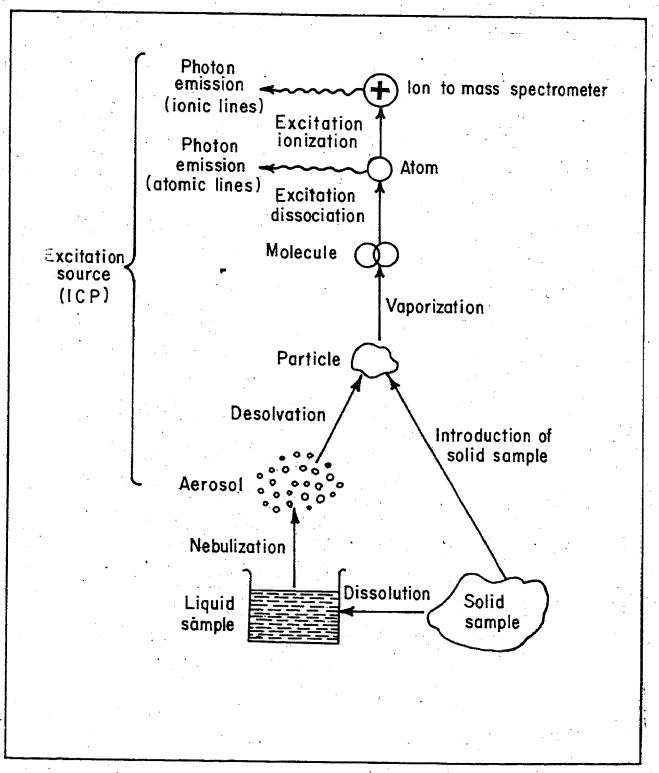

Figure 2. The chain of events leading from sample to the formation of ions.

efficiency of 90% or more[16]. A fraction of the positively charged ions produced in the plasma is transported through a narrow aperture of the sampler cone[19]. Here the plasma beam expands at supersonic speeds because of vacuum conditions (1 mbar) and is sampled by the skimmer cone. The ions and the plasma gas pass into a further high vacuum region (1×10^{-4} mbar) and pass through a system of electrostatic lenses which extract the positively charged ions and focus them in a form suitable for transmission through the quadrupole mass spectrometer which is kept in a very high vacuum region (2×10^{-6} mbar). The mass spectrometer transmits only ions of a particular mass to charge ratio, any neutral species accompanying the plasma gases would be taken away from the system by the vacuum pumps. This minimizes the ion–molecular collisions in the system. After mass isolation, the filtered ions pass into the detector system. An ion-detector system consisting of a channel electron multiplier is used in pulse-counting mode, to register the transmitted ions and generate a signal for every ion impinging upon its surface which will be amplified further. Since the number of registered ions from a given isotope, of course depends directly on the concentration of the relevant isotope (element) in the sample, quantification is straightforward. Design of the ion-optics makes the sampled ions to take a curved trajectory around a central photon stop eventually to be counted by an off-axis detector. This arrangement supresses photon noise as the detector is also sensitive to photon radiation from ICP[16] and produces a low background signal of only around 25 counts per second as against a count rate of about 1 lakh for a 50 ng/ml solution of a monoisotopic element like rhodium. Detection limits, mainly influenced by the relative abundance of the isotope selected for analysis for most elements are currently in the range 0.01 to 0.1 ng/ml (for example, the detection limits of rare earth elements in Table 4). These detection limits are obtainable under multielement operating conditions. For many elements, even better detection limits can be obtained if operating conditions for the plasma, ion optics and mass analyser are optimized exclusively for one element or a few elements of similar mass.

Performance characteristics and applications

The instruments constructed to date employ quardrupole mass analysers which yield essentially better than unit mass resolution over a mass range up to 300 amu. The analyser can scan very rapidly the entire useful mass range (0–240 amu) or a selected mass window of interest. A mass spectrum is normally obtained by many such repeat scans (say 100) which may take around 60 sec. This process of mass scanning is very rapid, and the instrument can obtain a spectrum for the entire mass

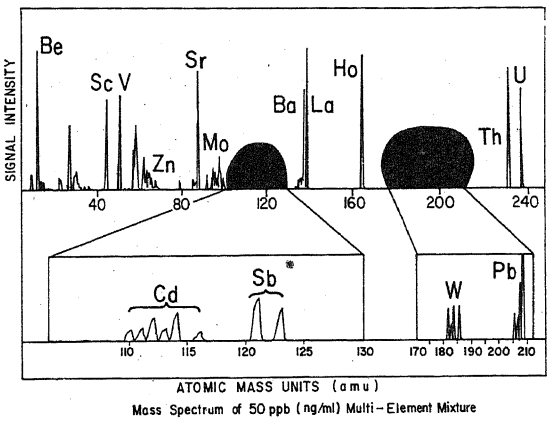

Figure 3. Mass spectrum of 50 ppb (ng/ml) multielement mixture.

range of ^{7}Li to ^{238}U in about 1 min. One such spectrum is shown in Figure 3 for a 50 ng/ml multielement solution, the position of the peak in the spectrum reveals the nature of the element (isotope) in the sample and the height of the peak its concentration. By comparing the mass peaks with those observed for a standard solution run under identical conditions, exact concentrations of different elements in any sample can be precisely calculated after making proper blank and interference corrections by an on-line computer. In place of mass scanning, peak jumping can also be used for data acquisition. Despite early claims that ICP–MS was relatively free from interferences[12], many workers noticed several kinds of interferences such as matrix effects either exclusively or in conjunction with a particular application[20, 21]. Evans and Giglio[22] have presented a comprehensive review of interferences in ICP–MS. Recently, Burton and Horlick[23] developed a graphically oriented data base of spectral interferences in ICP–MS, such as isobarics, oxides, doubly charged species, background- and matrix-dependent species, etc. This program is called 'MS Interview' which runs on a Macintosh Computer and helps the user to broadly assess the interference problems in ICP–MS. The most important limitation of this technique is nontolerance to high total dissolved solids in the sample solution. More than 0.4% of total dissolved solids cause clogging of the sampler and skimmer cones. For all practical purposes running of 0.1% solutions is recommended for obtaining reasonable long-term stability[24]. Others include the potential interferences from the background and sample matrix, periodic drift in the signal, space-charge and mass discrimination effects, etc. A few of these problems are minimized by the use of internal standardization[25], matrix-matching standards[26], addition of chemical modifier[27], isotope dilution[28], etc. during analysis.

The advantages of ICP–MS include: (i) very low detection limits which are considerably better than XRF and ICP-AES[26], (ii) much wider elemental coverage than by AAS or INAA, (iii) capability of doing multielement

analysis, unlike AAS with which we can estimate only one element at a time[29], (iv) considerably faster sample throughput at a rate of one sample in 3 min for the analysis of over 30 elements[30] and (v) the unique capability of providing a very rapid semiquantitative survey analysis for over 70 elements in an unknown sample[31]. Fulford and Quan[32] have studied the basic characteristics of negative ions such as F^-, C^-, Br^-, I^- and S^- in ICP–MS in the negative ion mode and revealed that they do not originate directly from the plasma but rather from electron capture or reaction downstream of the free jet expansion. They also indicated the possibility of sensitive detection of halogens, especially fluoride, which makes this mode particularly attractive where halogens are of

specific interest. Other advantages include isotopic analysis capability, relatively few interference effects, linear dynamic range for about 5–6 orders of magnitude, etc.

ICP–MS technique has been applied virtually to all types of samples, including geological[24,33], marine[34], biological[35], nuclear[36], freshwater[37], sea water[38], metallurgical[39], environmental[31], petroleum products[40], etc. There also have been a few instances of measuring trace elements by ICP–MS at pg/g levels in ultra-pure acids[41]. Although some samples like water could be aspirated directly, pretreatment is required in most cases. The trace element data obtained at our laboratory (Tables 1–3) on the hornblende mineral, water and precious-metal ore reference samples by ICP–MS demonstrate the potentials of ICP–MS in comparison with other popular analytical techniques. The methods used for sample preparation and other details are presented elsewhere[26,31,42,43]. The measurement precisions obtained on various trace elements are better than 5% relative standard deviation (RSD) with comparable accuracies.

Extending the capabilities of ICP–MS

ICP–MS was basically designed for multielement analysis of aqueous samples. In order to achieve accurate, reliable and sensitive results, especially when the concentrations of analyte elements in the original material or the prepared solution are too low to be determined directly by ICP–MS, or when matrix elements interfere with the determination, preconcentration and separation techniques are needed. In recent times, efforts have been successfully made to extend its capabilities by simple hyphenations to other techniques[44]. Some of them are discussed in the following:

Flow-injection method

Alternative sample introduction technique such as the flow injection analysis (FIA) when used in combination with ICP–MS is found to be very useful in agricultural, biochemical, clinical, pharmaceutical and environmental fields where smaller amounts of samples are available for analysis. This involves the injection of a discrete sample plug into a nonsegmented carrier stream. The sample moves into carrier stream from injection point to the ICP. A major limitation of ICP–MS is its sensitivity to the matrix (spectroscopic and nonspectroscopic interferences, clogging by solid deposition, etc.). When FIA preconcentration/separation techniques are employed, the analytes can be selectively separated from the bulk of the matrix[45] before injecting into ICP. The advantages include high throughput and minimal sample consumption. An example of effective utilization of FIA–ICP–MS is the estimation of very low levels of Cr, Ni and Pt in urine samples[46].

Electrothermal vaporization

Another alternative is to couple an electrothermal vaporization (ETV) unit to ICP–MS. ETV can be carried out using a metal filament or a heated graphite tube. Microlitre amounts of sample are injected into the tube, dried and then rapidly heated to approximately 3000°C to vaporize the sample, which is then transported to the ICP by using a carrier gas-flow. Rapid quadrupole scanning combined with multichannel data acquisition

allows the resultant transient signals to be captured and analysed[47]. This results in decrease of interference effects and improved sensitivity[48]. One interesting example of this technique is the determination of Os in geological materials[49] as it is very difficult to estimate Os in geological samples by solution nebulization.

Slurry nebulization

Although ICP–MS is designed for the analysis of solutions, it can be applied to solids if they are finely ground and suspended in water. Williams *et al.*[50] published a feasibility study of analysing slurry concentrations of 0.05 g per 100 ml of tetrasodium pyrophosphate as dispensing agent for finely ground (<3 μm) sample particles. Slurries of up to 1% w/v can indeed be nebulized using a high-solids nebulizer[51]. This approach is particularly useful for samples which are hard to dissolve[52].

Coupling with chromatographic techniques

Although many of the analytical techniques available today, including ICP–MS, are capable of determining elements at very low levels, most of them yield information only of total levels. Though ICP–MS can provide isotopic information, it cannot distinguish between different oxidation states of an element. At present there is an increasing demand to quantify the form or oxidation state of trace elements in a wide variety of samples. This is often termed metal speciation. Such information is very important to environmental scientists and toxicologists[6]. One of the most promising approaches to obtain trace metal speciation information is by combining an appropriate chromatographic technique to ICP–MS. Because of chromatography's separation power, coupling it to ICP–MS provides speciation capability. High-performance liquid chromatography (HPLC) is ideal as it employs solutions[44]. In general, the mobile phase must be selected carefully to prevent clogging of the interface, extinguishing of the plasma, etc. Low levels (a few per cent) of organic solvents in water can easily be tolerated by increasing the power and water-cooling the spray chamber (to condense and drain out as much solvent as possible). For higher levels, addition of oxygen to the plasma is required to burn out the carbon. By interfacing liquid chromatographic system with ICP–MS Huang and Jiang[53] have been able to accurately determine mercury species (total mercury and methyl mercury) in Dogfish Muscle reference material. Houk *et al.*[54] also used ion-pair reversed-phase HPLC to separate various cationic species of Hg and Pb in human urine.

A variety of high-efficiency nebulizers such as Mistral nebulizer[55], ultrasonic nebulizer[54], direct injection nebulizer[56], hydraulic nebulizer[57] and recycling nebulizer[58] have been successfully employed together with ICP–MS to realize the full potential of the technique. For example, memory effects associated with conventional pneumatic nebulization were found to be drastically reduced with direct injection nebulization[56].

Laser ablation

For the analysis of high-purity materials, such as high-pure metals, semiconductors, etc., sample treatment must be kept to an absolute minimum. This requirement has led to the development of a technique called laser ablation–ICP–MS (LA–ICP–MS). Gray[59] demonstrated the feasibility of laser ablation for solid sample introduction to ICP–MS for the first time in 1985. Laser ablation is an attractive alternative sample introduction technique to dissolution, particularly for handling geological materials[60]. A pulsed Nd:YAG laser is used to ablate solid samples held within an ablation cell. The laser is focused onto the surface of the solid sample, and controlled laser pulses of a millisecond duration vapourize the analyte material. The microparticulate cloud produced is carried by a stream of argon gas to the ICP torch and subsequently ionized within the plasma followed by mass spectrometric analysis. It is of particular importance to the nuclear, semiconductor, mineral and ceramic industries where information on several trace elements at μg/g and ng/g levels are needed without dissolving the sample. This technique can also provide very rapid semiquantitative analysis of materials of completely unknown composition[61]. LA–ICP–MS also offers the possibility of producing spatial information on element distribution at micrometer scale in solid materials[62]. This technique has also been applied to the characterization of spent nuclear fuels and to study the isotopic distributions of fission products and actinides in fuel pellets[63,64] and conductive (e.g. alloys powders) and nonconductive powder samples[65] (e.g. calcium sulphate and titanium dioxide powders for industrial use).

High resolution–ICP–multiple collector mass spectrometry (HR–ICP–MC–MS)

ICP–MS equipped with quadrupole mass analysers has been applied to the measurement of isotope ratios[60]. It is currently not possible to achieve precisions better than 0.1% RSD in routine analysis. This is not sufficient for geochronological studies and nuclear purposes. An unique instrument with ICP as source and incorporating a double focusing magnetic sector mass analyser equipped with multiple ion collectors has been recently developed[66]. The isotopic components were measured simultaneously which allowed high precision and high accuracy isotope ratio analysis (better than 0.01% RSD) which were comparable to those exhibited by TIMS[67]. It is also demonstrated recently that by combining laser ablation with HR–ICP–MC–MS, the isotopic composition

of solids can be measured directly to similar superior levels of precision and accuracy even for those elements such as W, Sn, Te, Mo, etc., which are difficult to ionize by thermal ionization[68]. High resolution ICP–MS offers detection limits better than 0.1 pg/ml in aqueous solutions for several elements. Table 4 gives the detection limits obtained by HR–ICP–MS for rare earth elements in comparison with those obtained by other multielement analytical techniques. We can see that the detection limits obtained by HR–ICP–MS are better by several orders of magnitude. This is a powerful analytical tool, especially when complex matrices like geological, ceramic, biological, sea water, etc. are investigated. Such matrices not only suffer from many spectral interferences such as isobaric overlaps, interferences from molecular ions, doubly charged ionic species, etc., which are well known but also from numerous unexpected spectral interferences which may additionally arise because of the complexity of these matrices and confuse the spectral interpretation. High resolution mass spectrometers keep the analyst free from most of the significant problems from spectral interferences in real samples while simultaneously improving sensitivity[69]. At least three firms, viz. FI Elemental Analysis, Winsford, UK (PlasmaTrace); Jeol Ltd, Tokyo, Japan, (JMS-Plamaxi1); and Finnigan MAT, Bremen, Germany (ELEMENT) have launched high resolution instruments during 1993.

Future directions

New developments in ICP–MS instrumentation and applications are advancing the understanding and the utility of the technique. The following are some of the areas where striking improvements can be expected in future.

i) During the nebulization of the samples, experience[70] has shown that approximately only one in one million ions sampled actually reaches the detector. This astonishing inefficiency of the present instruments suggests that further refinement of the design of the interface and ion-optics will improve the sensitivity further. Space-charge effects are thought to be a major cause of ion loss in ICP–MS. Briefly, as the beam leaves the skimmer cone it encounters the electric field of ion lens and the electrons are stripped away. The current from the ions remaining in the beam is far too high for the lens to tolerate so that the ion beam explodes, resulting in loss of ions. Active research is going on in this direction to minimize these effects. One firm (Hewlett-Packard, USA) has eliminated the need for a photon stop by mounting the quadrupole and detector off axis. An omega lens is used to bend the ion beam into the entrance aperture of the quadrupole. By this arrangement it is claimed that the new design has achieved a very high ion transmission with minimal space-charge effects, resulting in very low background and high sensitivity compared to the conventional systems[71].

ii) The normally operated nebulizers deliver only 1–2% of the sample to the plasma. This fraction can be increased roughly by an order of magnitude by using ultrasonic nebulizers as they produce smaller, more uniform droplets and is generally not prone to blockage and so is more efficient than pneumatic nebulizers[72]. Striking advances have already been made in this direction and some more may follow in future.

iii) Another effective way of minimizing the interference effects is to reduce the water load to the ICP by using the multiple desolvation[73] steps at –80°C for a continuous flow ultrasonic nebulizer. It has been observed that oxide and other polyatomic interferences were reduced by several orders of magnitude.

iv) As already discussed, one of the most effective methods of overcoming spectral interferences is to use high resolution ICP–MS, using a double focusing mass analyser to enable mass measurements at very high resolution (50,000 approx., the resolution is typically defined as $P = M/\Delta M$, where ΔM is the width of the peak at mass M at 5% of the peak height). At present these systems are finding applications in precise determination of stable isotopes and isotope ratios in geological and environmental studies[74].

v) One of the prominent areas of research in ICP–MS in recent times is the use of mixed gas plasmas[75] (addition of small amounts of oxygen or nitrogen or hydrogen to argon, or use of xenon or helium plasmas). The mixed gas plasmas have two major advantages in ICP–MS; reduction of polyatomic interferences and direct analysis of organic materials[76]. Use of helium as plasma gas is important because of its very high first ionization potential (24.5 eV) which exceeds that of argon (15.75 eV). Thus greater excitation and ionization of analyte ions is expected with the plasma. This is particularly important for sensitive estimations of elements such as halogens which are not efficiently ionized in argon plasma. Hence they are determined in negative ion mode in conventional ICP–MS.

Since its commercial introduction in 1983, ICP–MS has proved to be a versatile and powerful technique for handling routine analytical problems involving both elemental and isotopic analysis in a wide variety of matrices. By coupling alternative sampling techniques such as laser ablation, the ICP–MS technique is able to solve many analytical problems, not possible by other instrumental methods. Currently ICP–MS is a subject of very active research in the field of inorganic analytical chemistry and the instrument will continue to be an important asset to any chemical laboratory. The developments in ICP–MS, LA–ICP–MS and HR–ICP–MC–MS are expected to address both the technical and operational limitations of the present systems, eventually leading to more reliable, robust and low-cost instruments.

ACKNOWLEDGEMENTS. I thank Dr S. M. Naqvi for his valuable guidance and encouragement; Dr Sajid Husain, Analytical Division, Indian Institute of Chemical Technology, Hyderabad, for critical reading of the manuscript and helpful suggestions; Drs S. Nirmal Charan and M. V. Subba Rao (NGRI) for their helpful suggestions.

Climate change and agriculture – An Indian perspective

Sulochana Gadgil

In this paper, we examine the major predictions made so far regarding the nature of climate change and its impacts on our region in the light of the known errors of the set of models and the observations over this century. The major predictions of the climate models about the impact of increased concentration of greenhouse gases are at variance with the observations over the Indian region during the last century characterized by such increases and global warming. It is important to note that as far as the Indian region is concerned, the impact of year-to-year variation of the monsoon will continue to be dominant over longer period changes even in the presence of global warming. Recent studies have also brought out the uncertainties in the yields simulated by crop models. It is suggested that a deeper understanding of the links between climate and agricultural productivity is essential for generating reliable predictions of impact of climate change. Such an insight is also required for identifying cropping patterns and management practices which are tailored for sustained maximum yield in the face of the vagaries of the monsoon.

THE last decade has witnessed a rapid increase in the awareness of global change and triggered widespread apprehension amongst scientists and governments about the implications for their part of the globe. The major-facets of global change are changes in climate, the concentration of atmospheric constituents (such as CO_2, CH_4, etc.), land surface cover (e.g. desertification, deforestation) and biodiversity. The changes in these facets are of concern to us because of the impact on human beings and on resources critical to their survival. On the other hand, the changes in many of these facets have a large anthropogenic component, e.g. deforestation, loss in biodiversity, the increase in CO_2 due to burning of

Sulochana Gadgil is in the Centre for Atmospheric Sciences, Indian Institute of Science, Bangalore 560 012, India.

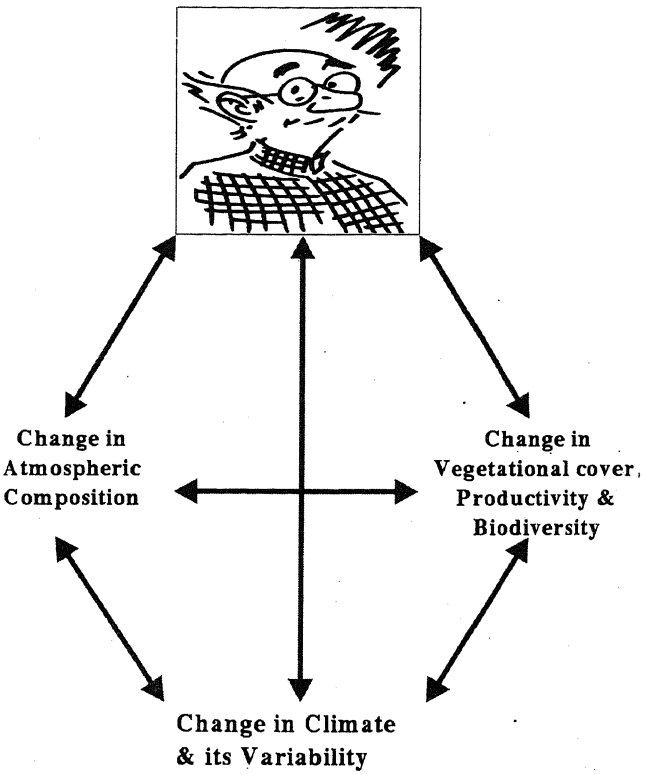

Figure 1. Major facets of global change – induced by and having an impact on humans.

fossil fuels, etc. It is important to note that many of these changes are interlinked (Figure 1). Thus increase in CO_2 (which is a greenhouse gas) can lead to climate change. Change in land surface cover can also have a large impact on the climate and particularly the rainfall in the tropics. Changes in atmospheric constituents can either have a direct impact on the inhabitants of the earth (such as higher incidence of skin cancer due to the depletion of ozone caused by the chloroflurocarbons (CFCs)) or an indirect impact via the induced change in climate as expected from the increase in CO_2.

I focus here on climate change. Climate change on long timescales of thousands of years, as between ice-ages and interglacials, is believed to be the result of natural factors such as changes in parameters of the earth's orbit around the sun. Anthropogenic factors are likely to have an impact on the timescales of about a century. Perhaps the most prominent facet of climate change over this century is global warming. The mean global surface temperature exhibits an increase over the last decades, with particularly sharp increase from 1970s (Figure 2). This warming has occurred during a period in which the composition of the atmosphere has changed significantly with a marked increase in the concentration of several gases contributing to the greenhouse effect such as carbon dioxide and methane (Figure 3). A major intergovernmental effort[1] in scientific assessment of climate change (IPCC) concluded that 'we are certain that emissions resulting from human activities are substantially increasing the atmospheric concentration of greenhouse gases such as CO_2, methane, CFCs, etc. These enhance the greenhouse effect, resulting in an additional warming of the earth's surface (on an average). The main greenhouse gas, water vapour, will increase in response to global warming and further enhance it.'

Several predictions have been made about the nature of climate change induced by an increased concentration of greenhouse gases and the possible impacts on critical resources such as agriculture. For example, a major study of implications for India of climate change[2] concludes 'cereal production is estimated to decrease and the nutrition security of the population-rich but land-hungry region of India would be hampered, an increase in the local tropical cyclone activity may occur over the next century, posing serious problems as large areas in the coastal regions have a dense population.'

Most of the studies using climate models to estimate change associated with enhancement of greenhouse gases suggest that the summer rainfall over South Asian region will increase by 5 to 15% (ref. 1). Some studies

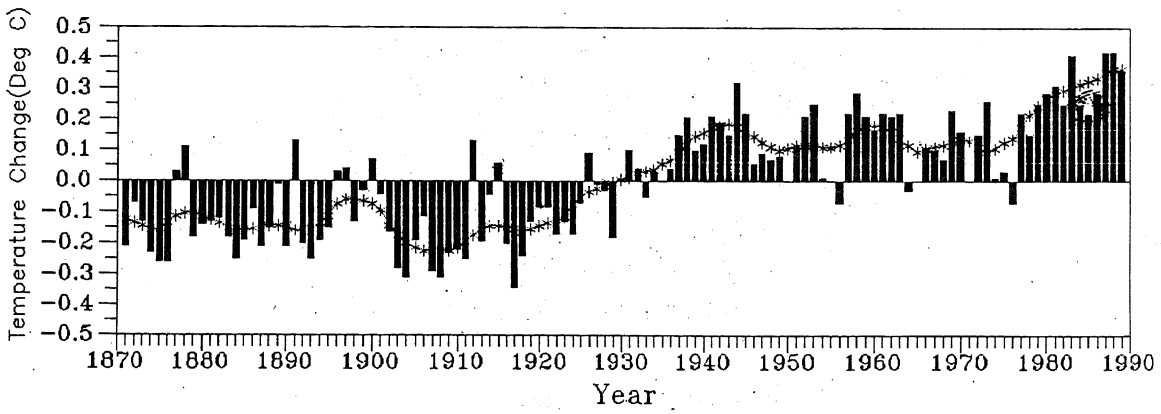

Figure 2. Annual deviation of the global mean combined land–air and sea-surface temperature for the period 1861–1989. The curve shows the results of a smoothing filter applied to the annual values.

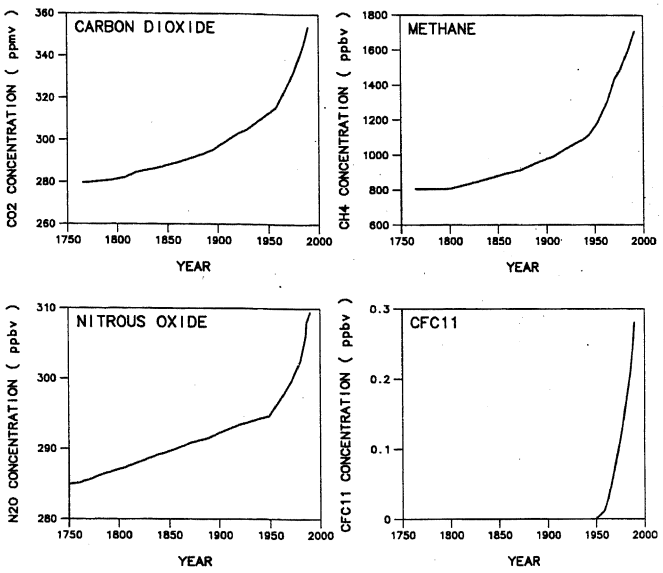

Figure 3. Variation of the concentration of some atmospheric constituents during the last century.

predict an increase in the intensity of daily rainfall events. In the thematic review of agriculture 'Climate Change over Asia', Suppiah *et al.*[3] state, 'Studies of simulated daily rainfall from enhanced greenhouse experiments indicate that a systematic increase in the average intensity is a common feature. Associated with this is an increase in the frequency of heavy rainfall events. Indeed, there is a reason to be more confident that rainfall intensity will increase in south and southeast Asian regions under enhanced greenhouse conditions. This pattern of change has serious implications for agricultural activities.' Parry and Swaminathan[4] suggest that 'the changes in climate could provoke serious reduction in food production potential, particularly in regions that are at present vulnerable to climate variability such as the agricultural zones in semi-arid and humid tropics'.

Such predictions about the nature of climate change and its impacts on agriculture are widely publicized. Thus the headlines of an article based on a study of Rosenzweig and Parry[5], which appeared in several newspapers across the country, read 'Impact of global warming to be hardest on have-nots. Less food if earth warms; more hunger in developing countries'. However, there is hardly any discussion about how reliable these predictions are. Predictions about the nature of climate change due to enhancing the concentration of greenhouse gases are generally made using climate models which are run for the present concentration and enhanced concentration of these gases. Assessments of impacts on agriculture such as that of Rosenzweig and Parry[5] involve using outputs of such models in conjunction with crop models and models of world trade. There are systematic errors in each of these models. Obviously, an assessment of the reliability of such predictions over the region of interest – here India, is an essential prerequisite to generating policy recommendations about possible mitigatory measures, and the strategies of research and development.

In this article, the major predictions made so far regarding the nature of climate change and its impacts for our region are examined in the light of the known errors of the set of models and observations over this century. The aim of this article is to identify problems which are of particular importance for our region and start a dialogue amongst concerned scientists to evolve a programme of research and development appropriate to the Indian situation.

Nature of climate change – Predictions and observation

Let us consider first the use of climate models for prediction of climate change and variability over the S. Asian monsoon region. It is important to note that simulation of the summer monsoon over this region has proved to be an extremely challenging problem. This is evident from Figure 4, in which the observed pattern of the mean rainfall for July is shown along with the mean pattern simulated by three atmospheric general circulation models (GCMs) for the period 1979–88 as a part of a

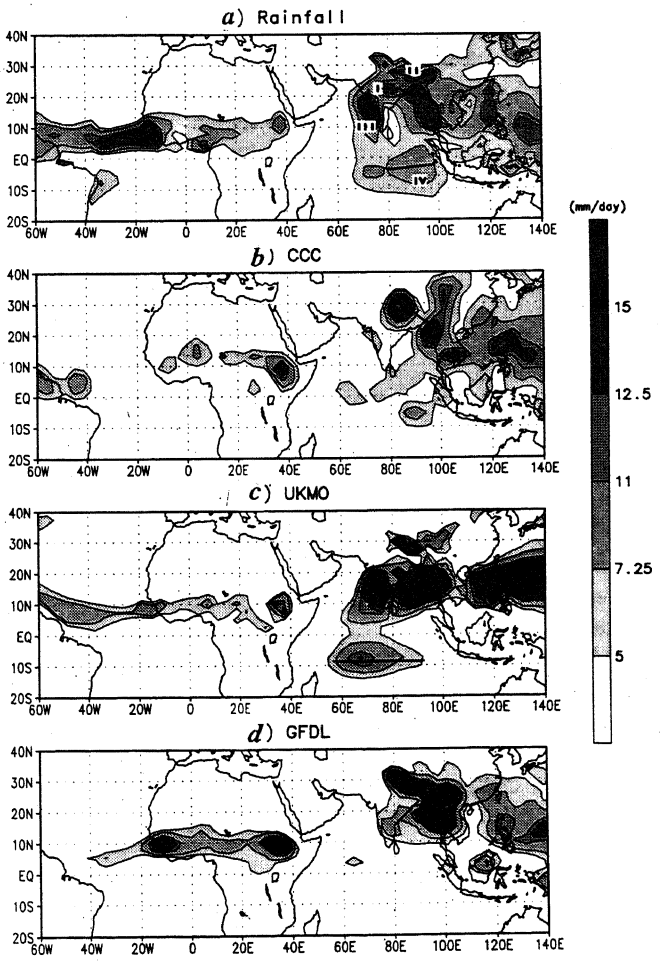

Figure 4. Mean rainfall pattern for July (*a*) observed patterns (*b*), (*c*), (*d*) simulated by three different atmospheric GCMs.

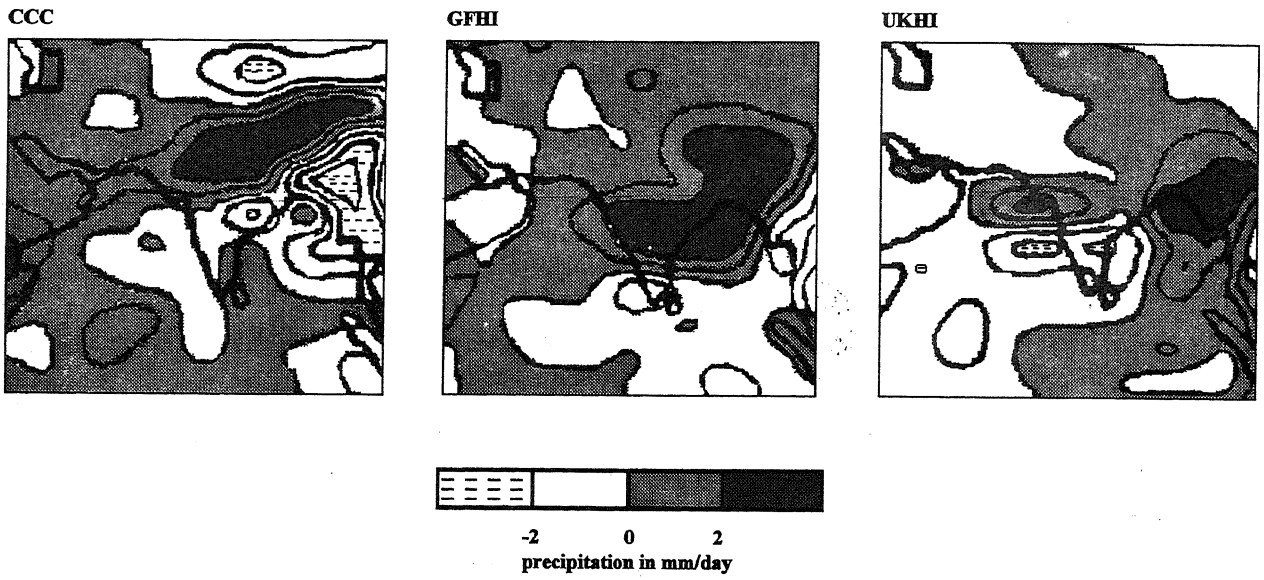

Figure 5. Change in precipitation (smoothed 10-year means) due to doubling CO_2 during June–August as simulated by some models (adapted from IPCC).

major Atmospheric Model Intercomparison Experiment[6]. It is important to note from Figure 4 *a* that while over the African region there is only one rainbelt around 10°N, over the Indian longitudes there are four. The large-scale monsoon rainfall is associated with the rainbelt I which extends north westward from the Bay of Bengal onto the Indian subcontinent. Northward of this monsoon rainbelt, is the rainbelt II along the foothills of the Himalayas. In addition, there is the rainbelt III along the west coast of the Indian peninsula due to the Sahyadris, and the rainbelt IV on the warm waters of the equatorial Indian ocean. The presence of so many favourable lacations for the rainbelt makes it extremely difficult for models to simulate the rainfall pattern realistically[7]. Generally only some of the rainbelts are simulated and that too not always at a realistic location. Thus, the CCC model simulates only the rainbelt II and the oceanic rainbelt IV. In the UK Meteorological Office (UKMO) simulation, the rainbelt over the continent is primarily on the peninsula, with hardly any rain over the monsoon zone (rainbelt I); the Himalayan belt II and oceanic belt IV are also simulated. The most realistic simulation of rainbelt I in Figure 4 is by the GFDL model. However, the oceanic belt IV is totally absent in the GFDL simulation. The simulation of the year-to-year variation of the summer monsoon over the Indian region is found to be even more difficult than that of the average pattern. Thus even models which simulate the mean pattern reasonably well, are not able to simulate realistically the interannual variation between poor and good monsoons[7].

So far we have been discussing simulation by atmospheric GCMs for the period 1979–88 with the sea surface temperature specified from observations. Because of the large inertia, the timescales of response of the ocean are much longer than those of the atmosphere. Hence for generating predictions over timescales of a week or less, or for studying subseasonal variation (such as fluctuations of the monsoon between active and dry spells), atmospheric GCMs run with specified sea surface temperatures are useful. However, for simulating variations on long timescales such as the century-scale on which we expect a change of greenhouse gas concentration to have an impact, it is necessary to use climate models in which the ocean is also an active player. These climate models are models of the coupled atmosphere–ocean system, which are necessarily more complex than the component atmospheric or ocean models. Not surprisingly, the simulation of the summer monsoon rainfall pattern by such models is also generally not realistic (e.g. Lal *et al.*[8]).

Some differences in the simulated and observed patterns of rainfall and its variability are to be expected. As Gates[9], one of the leaders in the field, has pointed out, 'The demand for climate scenarios for impact estimation far exceeds the supply of reliable information climate modelers have in their possession. Climate models certainly have systematic errors, most of these errors are poorly understood and, in general, poorly documented'. We have seen that it appears particularly difficult to simulate the South Asian monsoon and its variability by atmospheric GCMs or climate models, perhaps because of the presence of multiples equilibria[7]. Such limitations have to be borne in mind when we consider the implications of climate change derived by climate models.

Let us consider next the predictions made for enhanced greenhouse gases. The most authoritative review is by the IPCC[1]. While all models indicate that surface temperature

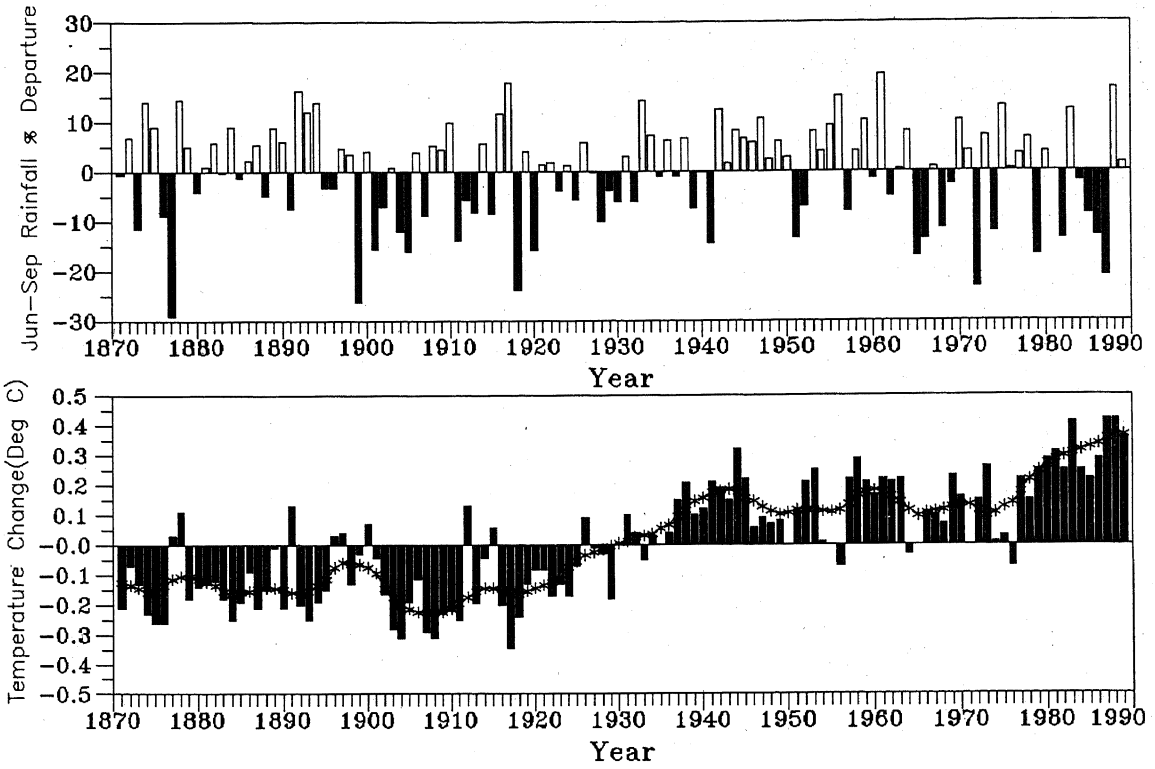

Figure 6 *a*. Variation of the all-India summer monsoon rainfall over the last century. Global warming of Figure 1 is also shown.

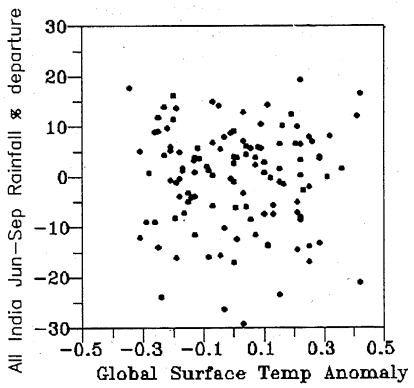

Figure 6 *b*. Percentage departure from normal of all-India summer monsoon rainfall versus global surface temperature anamoly.

will increase over the Indian region (up to 2°C during the summer) the response in terms of precipitation changes is more difficult to assess. Although most models simulate an enhancement of precipitation over the South Asian monsoon region, the change in precipitation is relatively small compared to the interannual variations. Also, there are considerable differences between models (Figure 5). However, all the three models shown in Figure 5 imply an increase over the region north of 20° N, i.e. over the monsoon zone of Figure 4 *a*, over which most of the large-scale monsoon rainfall is received. Lal *et al.*'s[10] study of anticipated changes in India's climate also suggests an increase in rainfall over this region.

Let us now consider how the prediction of an increase in the Indian monsoon rainfall in association with global warming compares with observations. The observed variation of the all-India summer monsoon rainfall over India over the last 100 years and the global warming during this period are shown in Figure 6 *a*. The variations of all-India rainfall over this short period of about a century do not seem to be correlated with the observed global warming (Figure 6 *b*). We note that there is no clear increasing trend observed on the century scale in Figure 6. *Rather, the most prominent variation is on the interannual scale (from year to year), between good and poor monsoons*. The change on the decadal or century scale is in the frequency of deficit monsoons or droughts. Joseph[11] was the first to point out that there are three distinct epochs in this series – the first up to about 1920, characterized by frequent droughts; the period 1930–64 by relatively less frequent droughts and the period 1965–87 again by frequent droughts. Thus what is important for the Indian region as far as change in climate is concerned, is the change (if any) in the frequency of extreme events such as droughts of floods, i.e.

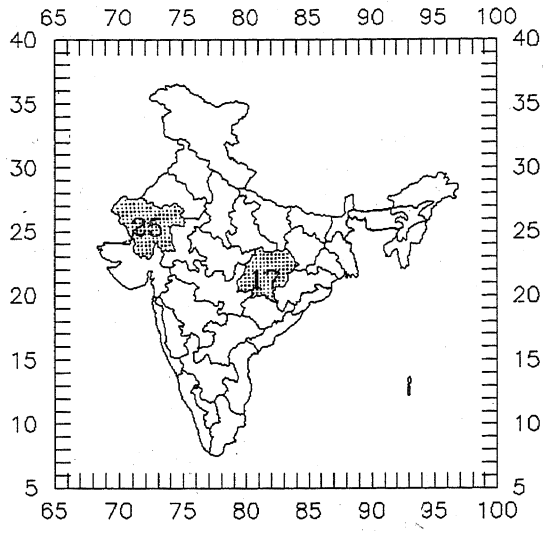

Figure 7 *a*. Coherent rainfall zones after Gadgil *et al.*[13].

changes in the important facets of climate variability. Although there are changes in the frequency of droughts on the decadal scale, these do not appear to be simply related to global warming[12]. For example, although the epoch of frequent droughts till 1920 coincides with the relatively low global temperatures, and the warming up to 1945 occurred in an epoch of low frequency of droughts, in the warm epoch during 1965–88, a high frequency of droughts is observed.

It is well known that the variations of seasonal rainfall over India do not occur in phase across the country. When some parts of India experience drought, there are floods in others, and so the average all-India rainfall is not very meaningful. Hence, we consider variations of rainfall over zones, which are coherent with respect to variations of the summer monsoon[13]. We find that there is no clear trend of increasing or decreasing rainfall over the century scale for any of the zones although there does appear to be some signal on decadal scales, leading to a persistence of above or below average rainfall for several years in a row (e.g. Figure 7). Earlier studies of trends over subdivisions or macrozones (reviewed by Pant *et al.*[14]) also found no significant trend over most of these regions. Rupa Kumar *et al.*'s[15] analysis of rainfall time-series at 306 stations across India showed that very few stations had significant trends.

An increase in the intensity of daily rainfall and frequency of heavy rainfall events has also been predicted[16]. The variation of the frequency of the heavy

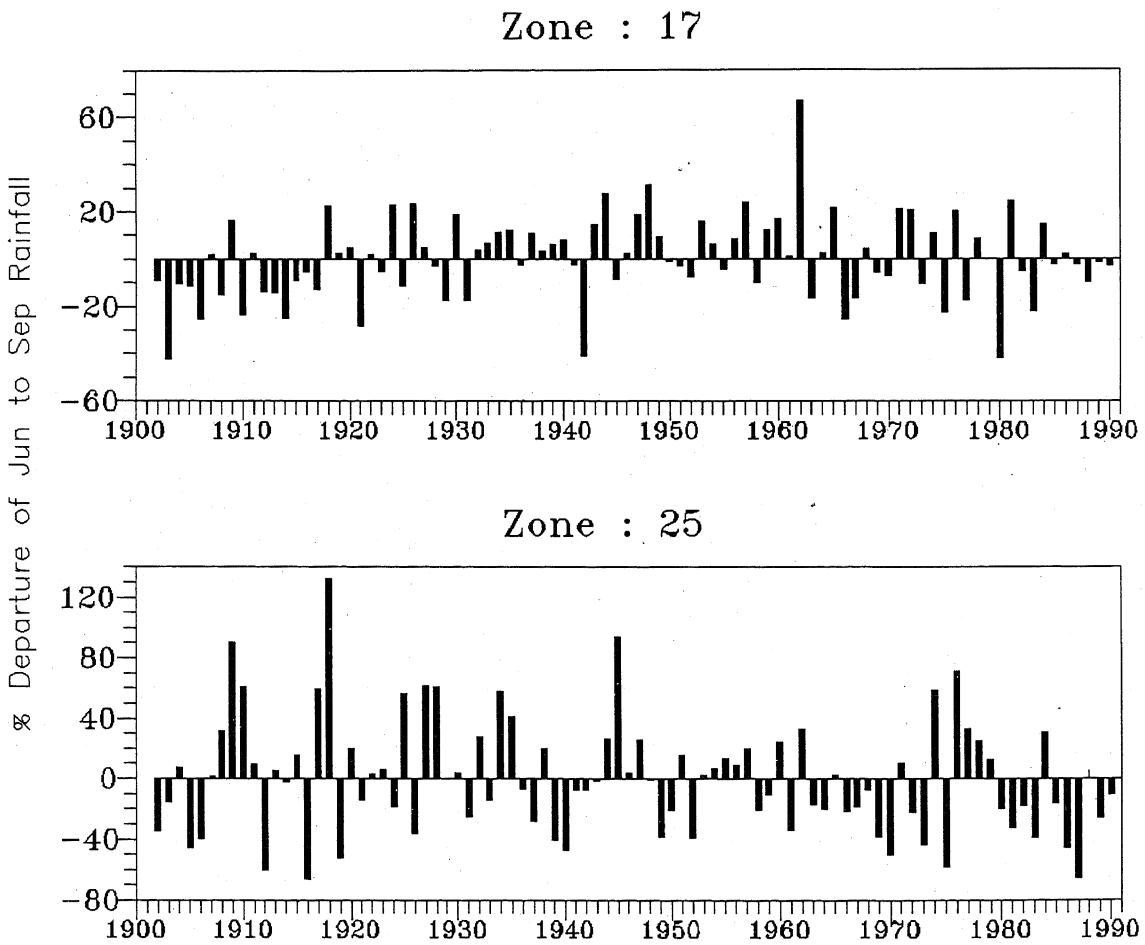

Figure 7 *b*. Variation of the summer monsoon rainfall over one zone 25 (below) over the North Western part of the monsoon zone, and zone 17 (above) over the eastern part of the monsoon zone.

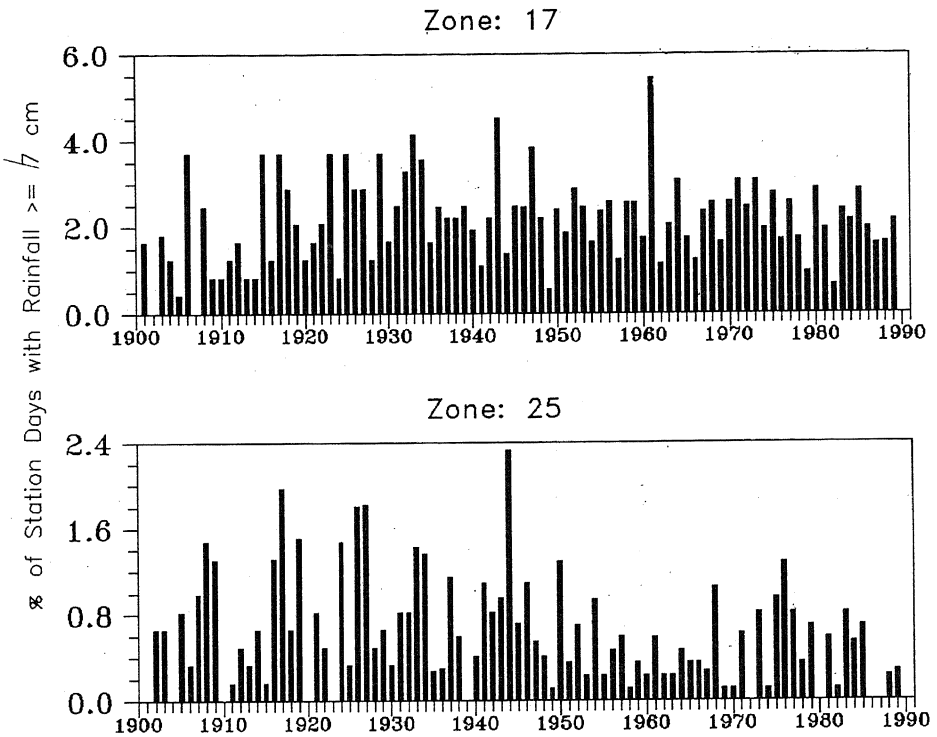

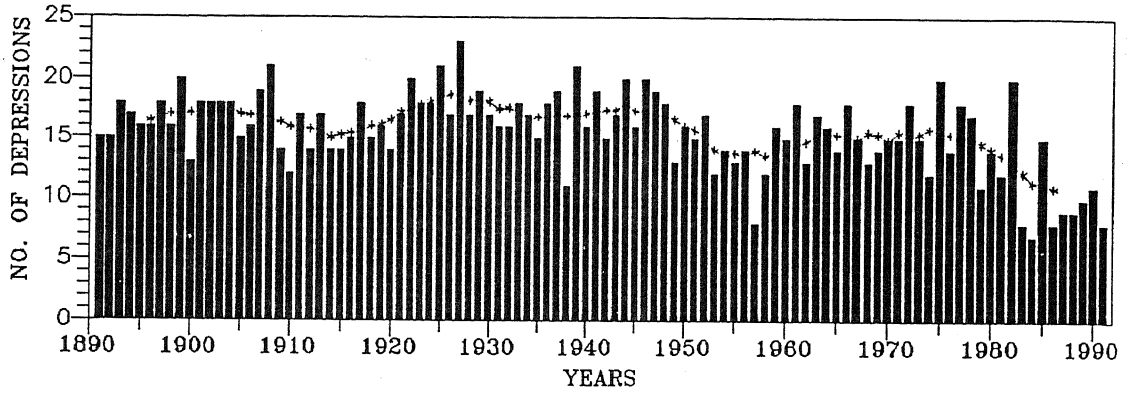

Figure 8. Variation of the frequency of heavy rainfall events (> 7 cm per day) over the two zones in Figure 7.

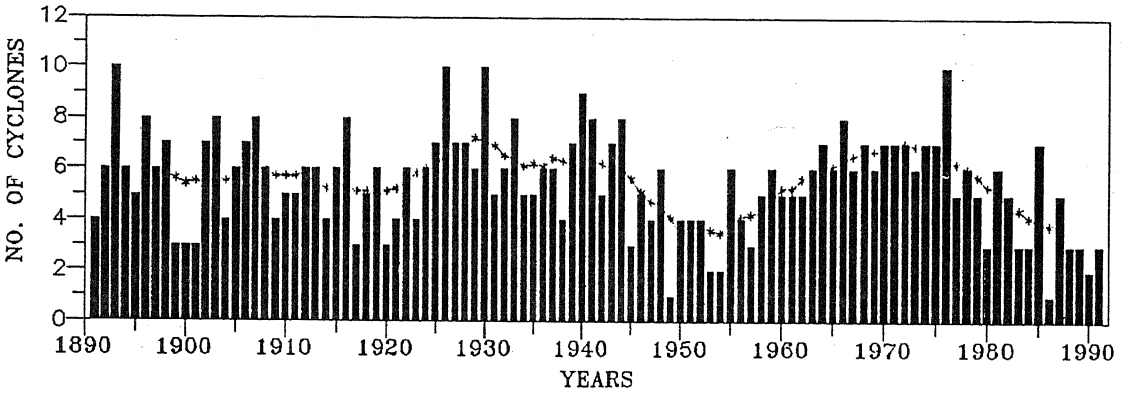
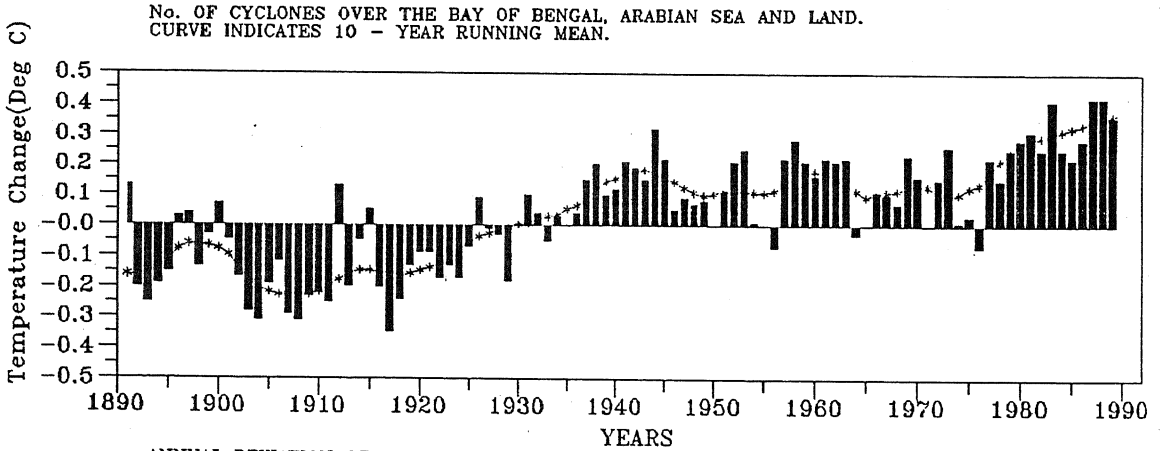
rainfall (greater than 7 cm a day) for two zones of Figure 7 is shown in Figure 8. Again there is no clear trend indicating increase of heavy rainfall events in association with global warming. In fact the frequency appears to decrease in the last two decades.



Another prediction is about a possible increase in frequency and intensity of tropical depressions and cyclones[10]. A detailed discussion about the nature of change in the depressions and cyclones over the last 100 years appears elsewhere[17]. The number of depressions and cyclones north of the equator in the Indian Ocean from Joseph's[17] study are shown in Figure 9. During the period 1970–90 when global warming is most rapid, the frequency of these systems is in fact decreasing. The frequency of tropical cyclones over the N. Atlantic also appears to have decreased in this period while there is no clear trend over the Pacific[18].

Studies of the observed changes in surface temperature over the Indian region have also been reviewed by Pant *et al.*[14]. The all-India mean annual surface temperature derived from 73 stations across India[19] shows a significant warming of 0.4°C per 100 years, which is comparable to the global mean trend of 0.3°C per 100 years. This increase is primarily contributed by the post-monsoon and winter seasons, there being hardly any trend in the monsoon-season temperatures. Of the 73 stations used to derive the all-India average, 30 stations show a significant warming trend while 6 show a cooling trend. *A comparison of the trends in rainfall[15] and temperature[19] indicates that generally increase in rainfall is associated with decrease in temperature.* In the belt north of 20°N where most models predict an increase, the eastern sector exhibits a decreasing trend while the western an increasing one, although neither is significant at a majority of the stations.



The observations about the variation of the summer monsoon rainfall over the Indian region over the last century during the period of global warming can be summarized as follows. The all-India summer monsoon rainfall does not exhibit an increasing trend; its variations do not appear to be correlated with global warming. No trends are apparent in the variation of the summer monsoon rainfall over different coherent zones of Indian region. There is no evidence to suggest that an increase in heavy rainfall events occurs with global warming. The frequency of depressions and cyclones over the Indian seas appears to have decreased markedly over the period 1970–90 when global warming was most

rapid. Hence the observations about the changes in rainfall pattern over the Indian region during this century appear to be at variance with the predictions generated so far by the existing climate models.

The all-India surface temperature does exhibit a warming as predicted by the models, albeit at a much smaller rate. However, over regions where rainfall increase is observed (again of very small amplitude) generally the temperature decreases. So the observations suggest that a simultaneous increase in rainfall and temperature is unlikely.

This comparison of model predictions regarding the important climatic variables – temperature and rainfall with available observational data – suggests that until the performance of the models in simulation for the regional scale is sufficiently accurate, regional predictions of the impact of various factors such as enhancement of greenhouse gases generated on the basis of the results from such models have to be interpreted with caution. The observations may not be adequate for detecting the climate change signal from the natural variability. However, before making decisions regarding actions for

mitigation, validation of the models by comparison with whatever observations are available for the major predictions, is absolutely essential.

Climate and agriculture

The strong links between the vagaries of the monsoon and agricultural productivity are well known. This link is evident in the variation of the production of rice and of the annual production of total food grain over India, shown in Figure 10, along with the all-India summer monsoon rainfall. It is clearly seen that superposed on the increasing trend due to the green revolution, are dips in the yield, which occur in years in which the all-India summer monsoon rainfall is deficit (e.g. 1965, 66, 72, 74, 79, 82). On the other hand, when the all-India rainfall is in excess of the normal (e.g. 1964, 70, 75, 78, 83), the yield is certainly higher. Thus the large year-to-year variations in monsoon rainfall are directly reflected

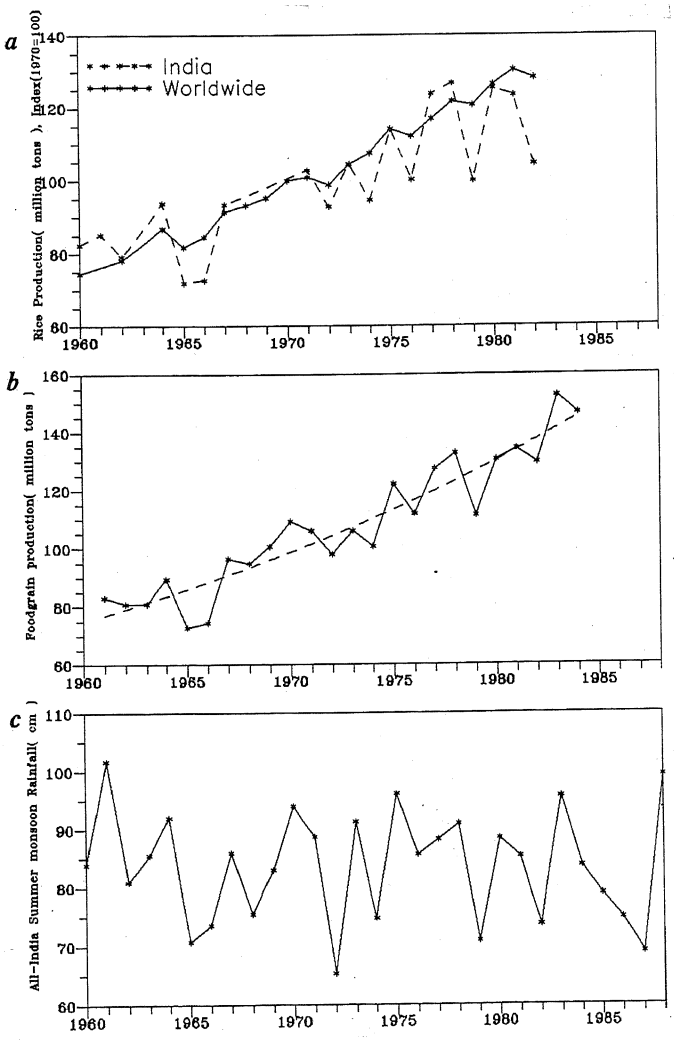

Figure 10. Variation during 1960–82 of (*a*) rice yield over the Indian region (after Swaminathan[23]), (*b*) total food grain production (after Parthsarathy *et al.*[24].), (*c*) all-India rainfall.

in substantive variations of the yield. For example, the difference in the total annual food grain production between the poor monsoon of 1974 and the succeeding good monsoon of 1975 is about 20% of the yield.

We note that in the epoch 1930–64 when the mean monsoon rainfall was high, the frequency of deficit years was low. Thus *a priori*, it would appear that if the monsoon rainfall were to increase (and frequency of droughts to decrease) as predicted by the climate models, the production of food grains would be enhanced. What then is the basis of the sensational predictions about decrease in yield with global warming? These are generated by the use of crop models to assess the impact of change in climate.

In general, the change in yield depends not only on the change in rainfall but also change in CO_2 concentration and temperature. While the increase in rainfall and concentration of CO_2 generally lead to an increase in yield, the impact of an increase in temperature is generally negative in the tropics. Thus if both rainfall and temperature increase, it is necessary to ascertain whether the impact of increased rainfall and CO_2 will overwhelm the impact of increased temperature and hence evapotranspiration over specific regions for specific crops. However, as noted in the last section, it is not clear that over the Indian region temperature and rainfall will simultaneously increase.

So far we have focused on interannual variation and considered primarily the impact of fluctuations in the total seasonal rainfall, mean temperature, etc. However, the agricultural productivity is also a sensitive function of the distribution of the meteorological variables such as rainfall within a season[20]. The difference between a so-called good monsoon season and a deficit monsoon season is generally the presence of a long dry spell in the latter. Such dry spells induce moisture stress and have a major impact on the productivity when they occur in critical life history stages of the crop. Similarly if wet spells occur and promote the spread of pests and diseases, significant losses are incurred unless mitigatory measures are adopted[21]. The identification of such weather/climate events which have a large impact on the productivity of different crops is essential for making realistic impact assessments and choosing the appropriate management strategies for mitigatory measures.

With the rich data-set available in the meteorology department, the probabilities of the occurrence of such events in different stages in crop growth can be readily worked out for each region. For obtaining maximum sustainable yield in the face of this variability, the varieties and cropping patterns have to be chosen so that the occurrence of such events in the critical life-history stages is minimized. Thus, understanding such links between climate variability and agricultural productivity is also a pre-requisite to tailoring cropping patterns/varieties and management practices for maximum sustainable yields in different agroclimatic zones.

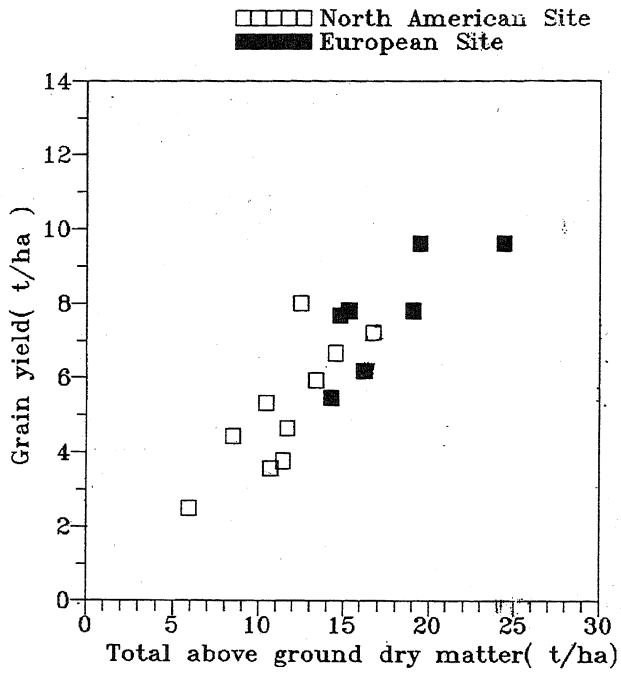

Figure 11. Scatter plot of simulated yield against biomass for the North American site and European site in the GCTE (after Ingram[22]).

A systematic analysis of the yields simulated by wheat models was recently conducted as a part of the IGBP Project on Global Change and Terrestrial Ecosystems (GCTE). This revealed a surprisingly large intermodel variation in simulated yield even when the climatic conditions were specified to be the same (Figure 11, after Ingram[22]). Thus it appears that the prediction of impact generated by using crop models in combination with climate models are likely to have significant errors. It is necessary to understand and validate each component/link with available observations and special field trials to determine the reliability of the predictions. For example, it may be worthwhile to investigate whether the existing crop models (of the kind used in Rosenzeweig and Parry's[5] study) can simulate the observed variation of the yields over the last century when the observed variation of the climatic parameters is specified.

It is also important to note that as far as the Indian region is concerned, the impact of year-to-year variations of the monsoon will continue to be dominant even in the presence of global warming. Thus neither the rainfall nor temperature is likely to change monotonically. The pertinent question to ask of climate models and observations is then the extent to which climate variability will change. In other words, on the interannual scale whether the frequency of extreme events such as droughts or floods will change and on the subseasonal scale whether the frequency of critical weather events such as dry and wet spells or hot and cold spells will change.

Concluding remarks

We have seen that predictions generated from climate models about the consequences of enhanced greenhouse gases such as increased monsoon rainfall, higher frequency of heavy rainfall events, etc. are at variance with observations over the last century characterized by global warming. Recent studies have also brought out the uncertainties in the yield simulated by crop models. Thus it is clear that understanding the important links between climate and agricultural productivity is an essential prerequisite to generating reliable predictions about impact of change in climate and variability.

In my view, the most important problem for our region is to elucidate in detail the climate component of agricultural productivity by systematic analysis of the available data on yields of different crops (at the different agricultural research stations as well as at district level) on the one hand and investigation and development (if necessary) of crop models with realistic sensitivity to climate on the other. This will pave the way for generating realistic impact assessments and identifying cropping patterns and management strategies which are tailored for sustained maximum yield in the face of the vagaries of the monsoon.

Meanwhile, we expect the rapid improvement of climate models across the globe in the last decade to be sustained. In the not too distant a future, these models should start yielding reliable results on regional scale for the nature of climate change in response to various factors such as enhanced greenhouse gases. By that time if the links to the productivity of the major crops are understood, reliable predictions of impact could be generated and strategies for coping with the anticipated climate change worked out.

REVIEW ARTICLES

Opioid peptides in invertebrates: Localization, distribution and possible functional roles

R. Nagabhushanam, R. Sarojini, P. S. Reddy, M. Devi and M. Fingerman

Department of Ecology, Evolution, and Organismal Biology, Tulane University, New Orleans, Louisiana 70118, USA

In this review the opioids that have been found in the invertebrates are discussed. Major emphasis is placed on the arthropods, molluscs and annelids. The article deals largely with the identification and functional roles of these peptides. These endogenous opioids are involved in a wide variety of physiological processes, often serving as neurotransmitter substances. Among the putative roles of opioids in invertebrates are mediation of the release of neurohormones, initiation of proper behavioural responses, control of thermoregulatory activities and mediation of immune responses. This review concludes with a section that suggests areas of future investigation, along with possible practical applications of these compounds.

IN recent years a number of vertebrate-type neuropeptides have been discovered in the invertebrates. The discovery of these vertebrate-type peptides in invertebrate tissues has influenced research in comparative endocrinology in a major way. A class of such neuropeptides is known as the opioid family, based on the fact that among vertebrates these peptides show a potent capacity to mimic some key actions of morphine[1]. In mammals the enkephalins originate from at least two precursors, preproenkephalins A and B. Preproenkephalin A gives rise to one copy of leucine enkephalin (Leu-Enk), four copies of methionine enkephalin (Met-Enk) (Leu-Enk and Met-Enk are pentapeptides) and two C-terminally extended enkephalins, Met-Enk-Arg^6-Phe^7 (met-7) and Met-Enk-Arg^6-Gly^7-Leu^8 (Met-8)[2]. Preproenkephalin B contains no Met-Enk sequence but has three Leu-Enk-containing peptides, α/β-neoendorphin, dynorphin and rimorphin. The first enkephalins discovered, Met-Enk and Leu-Enk, were originally purified from the porcine brain[3]. There are a variety of opiate receptors (mu, delta, iota, kappa, epsilon) each of which appears to be the preferential ligand for one of the endogenous opioid peptides in mammals[4]. Endogenous opioids have been detected in all vertebrate species investigated[5,6]. These substances serve widely throughout the body as neuromodulatory substances.

The search for the presence of endogenous opioids in invertebrates initially met with some uncertainty. Early reports did not support the presence in several invertebrates of opiate-receptor-binding sites[7,8]. However, the development of appropriate techniques, especially immunocytochemistry, radioimmunoassay (RIA) and high-performance liquid chromatography (HPLC), made it possible to discover opioid peptides in several invertebrates. Among the invertebrates, studies have been undertaken mainly with arthropods, molluscs and annelids, and in this review we emphasize the studies that have been done on the localization, distribution and possible roles of the endogenous opioids in these groups.

Crustacea

Localization and distribution

The first opioid study on a crustacean was reported in 1981 by Mancillas *et al.*[9]. Through immunocytochemistry they found Leu-Enk-like immunoreactivity in all the retinular cells of the spiny lobster *Panulirus interruptus* and the red swamp crayfish *Procambarus clarkii*. In addition, such immunoreactivity was also apparent in nerve fibres in chiasm 3 that run from the medulla interna to the medulla terminalis. Since then immunocytochemical mapping studies, which not only detect the presence of opioid peptides but also give their distribution, have been reported in a variety of crustaceans. Table 1 summarizes the peptides detected so far in crustaceans and the techniques used to demonstrate their presence[9–11,14–22]. Marino *et al.*[12] and Piccoli *et al.*[13], by using a receptor-binding assay, reported the presence of opioid-like peptides in the suboesophageal ganglion and brain of *Squilla mantis* and *Carcinus maenas*. There are a few reports about the presence of enzymes that degrade the opioid peptides in Crustacea. Colleti-Previero *et al.*[23] found three peptidases in the haemolymph of the crayfish *Astacus fluviatilis* that rapidly degrade Leu-Enk. Watabe *et al.*[24] reported evidence for the presence of β-endorphin-degrading enzymes in the cells of the hepatopancreas of the crayfish *Procambarus clarkii*.

Functions

Behaviour. The first study of a possible role of an opioid in any crustacean was that by Maldonado and Miralto[25] with *Squilla mantis*. They found that the defensive response, a rapid flexure of the abdomen, which can be experimentally induced by electric shock, can be modified by morphine. This drug increases the threshold current required to elicit the response. The loss of sensitivity is dose-related. Naloxone blocks the action of this opioid. Naloxone is a competitive opioid antagonist, binding to opioid receptors. Martinez *et al.*[26] found that when the crab *Gecarcinus lateralis* was placed into the activity-monitoring chambers, the locomotor activity increased. FK 33 824, a stable Met-Enk analogue, markedly enhances this initial activity but naloxone blocks this excitatory action of the opioid. In studies with another crab, *Chasmagnathus granulatus*, Lozada *et al.*[27] found that this crab assumes a defensive posture, with both chelae extended and the body elevated when an electric shock of 50 Hz, 1 s duration and at least 8 V is given. Morphine produces a dose-dependent reduction in the sensitivity of this crab to the electric shock. But when naloxone was coinjected with morphine, no reduction in sensitivity occurred, which suggests that the morphine was acting through opioid receptors and that such receptors are indeed involved in this reduction of sensitivity to the electric shock. In other behavioural studies with this crab[28,29], it was found that a danger stimulus in the form of a passing shadow elicits an escape response that habituates after repeated stimulation, and that this habituation appears to be mediated by endorphins. Support for this suggestion that habituation is the result of endorphin release is the observation that naloxone increases the responsiveness to the danger signal and after a habituation session which reduces the response level to the danger signal there is also an analgesic effect on the defensive response of this crab to an electrical shock. Very recently, Godoy and Maldonado[30] reported that the synthetic opioid analogue (D-Ala^2) Met-enkephalin (DAME) significantly reduces the escape response to a danger stimulus in the crab *Chasmagnathus granulatus* when administered within a dose range of 0.01–1.0 μg/g. A 0.1 μg/g dose of naloxone has no effect *per se* on the response, but when it is administered together with DAME, it completely blocks the decremental effect of this drug.

Pigmentary effectors. Crustaceans have two types of pigmentary effectors: (a) the chromatophores, which are responsible for colour changes and (b) the retinal pigments, which control the amount of light impinging on the rhabdom. Translocation of the pigments in the chromatophores and at least in the distal and reflecting pigments is clearly regulated by neurohormones.

(a) *Chromatophores.* The physiology of crustacean chromatophores has been reviewed recently[31]. In several species dual control of chromatophores by pigment-dispersing and pigment-concentrating neurohormones has been demonstrated. In this laboratory we have been particularly interested in identifying the neuroregulators that control the release of crustacean neurohormones. In the fiddler crab *Uca pugilator*, 5-hydroxytryptamine (5-HT) stimulates the release of red-pigment-dispersing hormone while norepinephrine (NE) stimulates the release of black-pigment-dispersing hormone. Met-Enk, but not Leu-Enk, was found to stimulate the concentration of the black and red pigments in intact *Uca pugilator*[32]. In *in vitro* experiments Met-Enk stimulated the release of black- and red-pigment-concentrating hormones from isolated eyestalks[32,33]. Naloxone blocked the action of Met-Enk in intact crabs and on isolated eyestalks. Met-Enk, like the classical aminergic neurotransmitters, has no direct effect on these chromatophores, as evidenced by the lack of effect on the chromatophores in isolated legs. Presumably, therefore, 5-HT, NE and Met-Enk exert their effect only indirectly, by stimulating the release of the appropriate specific chromatophorotropic neurohormones. However, surprisingly, β-endorphin was found to produce black-pigment dispersion in both intact *Uca pugilator* and in isolated legs[32]. Additional evidence for the involvement of enkephalinergic substances

in crustacean colour changes was provided by Martinez *et al.*[34], who found that although injection of the stable Met-Enk analogue FK 33 824 alone into *Gecarcinus lateralis* has no effect on the chromatophores, coinjection of this analogue with eyestalk extract strongly potentiates the black-pigment-dispersing and red-pigment-concentrating actions of the eyestalk extract. This potentiation is blocked by naloxone.

(b) *Distal retinal pigment.* NE produces light adaptation of the distal retinal pigment of *Uca pugilator* whereas dopamine (DA) induces dark adaptation[35,36], presumably by stimulating the release of the light-adapting and dark-adapting neurohormones, respectively. Met-Enk, like DA, produces dark adaptations of this pigment, but Leu-Enk has no effect on this pigment[37].

Blood glucose. The crustacean hyperglycaemic hormone (CHH) is found in the sinus gland. In several crustaceans CHH release has been found to be triggered by 5-HT (ref. 38). Recently, Lüschen *et al.*[17] and Rothe *et al.*[18] provided evidence that synthetic Leu-Enk, endogenous sequenced Leu-Enk isolated from thoracic ganglia of *Carcinus maenas* and purified Leu-Enk-like material from sinus glands of this crab, when injected into intact *Uca pugilator*, the test organism for these bioassays, produce a decrease in the haemolymph glucose concentration. Also, in CHH bioassay done again by injecting into intact *Uca pugilator*, it was found that eyestalks of *Carcinus* incubated in the presence of synthetic Leu-Enk release less than the basal level of CHH was compared to eyestalks incubated in saline alone. Furthermore, injection of naloxone into intact *Uca pugilator* prior to injection of Leu-Enk blocks the hypoglycaemic action of this opioid in this crab. In contrast, Leu-Enk does not affect the haemolymph glucose concentration in eyestalkless fiddler crabs, which is consistent with the hypothesis that the enkephalin acts by reducing CHH output from the sinus glands in the eyestalks. In the crayfish *Astacus leptodactylus*, Met-Enk decreases the haemolymph glucose level as well as the nocturnal peak in the circadian rhythm of haemolymph glucose[39]. Sarojini *et al.*[40] provided evidence that both L-Enk and DA are involved in the regulation of blood glucose in the crayfish *Procambarus clarkii*. *In vitro*, both L-Enk and DA reduced the rate of release of CHH from isolated eyestalk neuroendocrine tissue. These results suggest that both L-Enk and DA act to inhibit the release of CHH by affecting the eyestalk neuroendocrine complex and that the

enkephalinergic inhibitory neuron follows the dopaminergic inhibitory neuron in the chain of neurons which leads to the neuroendocrine cells that secrete CHH.

Reproduction. The potential involvement of an endogenous opioid system in the regulation of ovarian development in the *Uca pugilator* was investigated *in vivo*[41]. Injection of synthetic Met-Enk into female crabs slowed ovarian maturation significantly. The inhibition was dose-dependent. The mean ovarian index and the mean oocyte diameter of the crabs that received the opioid were significantly smaller than the corresponding values for the saline-injected concurrent control specimens. Injection of naloxone produced dose-related ovarian maturation[41].

Insecta

Localization and distribution

The first demonstration of the presence of an opioid in an invertebrate came from an RIA study with the brain of a locust, *Locusta migratoria*[42]. No β-endorphin was found but Leu-Enk and Met-Enk were both present, with Met-Enk present in larger quantity than Leu-Enk. Since then immunocytochemical studies based on antisera raised against opioid peptides have been carried out in about 35 species of insects belonging to eight orders[43,44]. Table 2 summarizes the results so far obtained regarding the localization and distribution of opioid peptides in insects as well as the methods employed to detect these peptides[45–66]. A few investigators have demonstrated the presence of opioid-binding sites in insect neural tissues. Pert and Taylor[68] showed that membranes prepared from heads of *Drosophila melanogaster* bind Leu-Enk, but naloxone does not bind well to these membranes. D-ala-2-met-5-enkephalinamide (DAMA) also binds extensively to cerebral ganglion membrane suspensions from *Leucophaea maderae*[67]. In the same insect, high-affinity stereospecific opioid binding was demonstrated in midgut preparations[69]. Santoro *et al.*[70] reported that tissues of *Drosophila* appear to contain kappa-like opioid receptors. These results suggest that insects possess both opioid substances and their receptors, thus revealing the existence of a complex opioid mechanism similar to mammals. Recently, Lamango and Isaac[71] characterized an endopeptidase from the heads of *Musca domestica* that can degrade a range of neuropeptides, including enkephalins and substance P.

Functions

Neuromodulation. Morphological evidence suggests the existence of specific enkephalinergic pathways within the central nervous system (CNS) of insects[43]. Immunoreactive nerve fibres originating in the brain were seen in nerves issuing from the corpora cardiaca (CC) and running along pathways leading to the anterior sympathetic nervous system and corpora allata (CA). These opioid peptides may be functioning as neurotransmitter or neuromodulatory substances[43]. In *Calliphora vomitoria*, the heart has a direct enkephalinergic innervation, particularly by Met-7 immunoreactive terminals in the vicinity of the ostia; the enkephalin-like material presumably acts as a neuromodulator of the intrinsic heart rhythm[43]. In addition, in this insect the phasic secretory activity of the CA is regulated by enkephalin-like peptide[43].

Neurohormone. The presence of enkephalins in the neurohaemal areas of the dorsal neural sheath of the thoracic ganglia of *Calliphora vomitoria* suggests a hormonal role for these peptides[43]. Furthermore, a close association between 5-HT and a variety of peptidergic substances, including Leu-Enk and Met-7, was observed. Met-7 at a concentration of as low as 10^{-12} M displayed a powerful stimulatory influence on salivary gland secretion in the rat. In contrast, Leu-Enk and Met-Enk were completely without effect. Naloxone failed to inhibit this response of the rat on salivary glands to Met-7. Thorpe and Duve[43] suggested that Met-7 may act through kappa receptors, where naloxone has only a weak binding capacity.

Behaviour. A behavioural role for an enkephalin in regulating locomotor activity in the cockroach *Leucophaea maderae* was demonstrated by Ford *et al.*[72]. When the enkephalin analogue D-ala-2-met-5-enkephalinamide (DAMA) was applied topically to the cerebral ganglia, it resulted in a decrease in locomotor activity. Naloxone can block this effect as well as the depressant effect of morphine on locomotor activity. In contrast, another analogue, D-ala-2-leu-5-enkephalinamide (DALA) and also dynorphin increased the locomotor activity. This acceleratory effect can also be antagonized by concomitant naloxone treatment. In another cockroach, *Periplanata americana*, enhanced locomotor activity was induced by morphine, a mu opioid agonist[73]. In the same species, it was shown that the kappa opiate agonist U-50,488H was able to stimulate the ingestive responses of free-feeding animals. These results on opioid-induced behaviours indicate the presence of multiple opiate receptor types in insects.

Thermoregulation. Survival of an animal is dependent on its ability to avoid thermal extremes. Many ectotherms show at least a primitive ability to control their body temperature. The behavioural thermoregulatory responses of at least some insects are sensitive to opiates. Kavaliers and Hirst[74] studied the thermal responses of larvae of the mealworm *Tenebrio molitor*. Fourth instar larvae were injected with morphine, Met-Enk, β-endorphin,

or naloxone. Their behaviour and temperature preference were recorded following their return to pretreatment locations in a thermal gradient with a low temperature of 20°C and a high temperature of 40°C. Prior to drug treatment, the larvae showed a preference for a temperature of about 32°C. After injection, animals given morphine or Met-Enk moved towards higher temperatures whereas those receiving naloxone did not. Larvae receiving β-endorphin displayed no consistent changes in thermal preference. The changes in preferred

temperatures that took place were evident for approximately 1 h, after which animals returned to the pretreatment preference temperature[74].

Immune response. Among recent developments in the elucidation of opioid activities in nonnervous cells and tissues, endogenous opioids in the immune system are receiving the greatest attention in insects. The endogenous opioids in *Leucophaea maderae* appear to influence the autoregulatory activities of immunocompetent cells. These activities include the adherence and migratory behaviour of these cells[75]. There is evidence for the presence in immunocytes, as well as in cell-free haemolymph, of Met-Enk, which appears to be involved in immunoregulatory activities, perhaps by interaction with a special subtype of delta receptor. Moreover, the naloxone has an inhibitory effect on these processes, which indicates that they are receptor-mediated[75]. Thus, there appears to be a link between the neuroendocrine and the 'immune' system in insects[76].

Mollusca

Identification and localization

Tremblay *et al.*[77] seem to have been the first investigators to demonstrate the action of an opiate peptide in a mollusc. Injection of morphine into the gastropod *Aplysia californica* decreased the available neurotransmitter, acetylcholine. Erdélyi *et al.*[78] demonstrated that in the snail *Helix pomatia* Leu-Enk induces hyperpolarization of some neurons in the brain, and naloxone administration antagonizes the action of this opioid. These results suggest the presence of an endogenous opioid system in gastropod molluscs. By use of immunocytochemical techniques, a very detailed study of the immunoreactive material present in the central nervous system of the pond snail *Lymnaea stagnalis* has been performed by Schot *et al.*[79]. However, Met-Enk-like material was observed only in the cerebral and pedal ganglia. In each cerebral ganglion a cluster of 10–15 immunoreactive cells lies in the mediolateral part of the ganglion; another cluster (6–10 cells) is just dorsal to the lateral lobe. In addition, two positively reacting cells were observed in the medioventral area. Numerous positive axonal terminals were seen along the entire periphery of the cerebral commissure. In each pedal ganglion a group of 31–40 immunoreactive cells, located laterally, show a positive reaction for Met-Enk. A second group (8–10 cells) lies in the ventromedial area of the ganglion. Such immunocytochemical studies have been extended to other molluscs. Table 3 summarizes the evidence for the presence of opioids in various molluscs so far investigated[79–81,83–95]. Using HPLC, Leung *et al.*[82] identified a substance in the abdominal ganglion of *Aplysia californica* that was able to displace DAMA. In the nervous system of *Mytilus*, evidence was obtained for two classes of opioid-binding sites in nervous tissue[96,97]. It was suggested that the two binding sites may be associated with presynaptic and postsynaptic receptor sites for the opioids, or possibly with different pharmacological subtypes of receptors[98].

Functions

Behaviour. In the land snail *Helix pomatia* morphine induces a state of immobilization and muscle rigidity, resulting in a loss of the righting reflex. These effects are reversible by naloxone treatment[99,100]. This behavioural effect of morphine is reduced as treatments progress for four days and reoccurs if a higher dose of morphine is given on the fifth day, thus demonstrating that tolerance has occurred. It was suggested that in these molluscan behavioural responses enkephalins can mediate sensory neurotransmission[101]. Electrophysiologically, opioids are known to elicit a variety of actions in molluscan neurons, including both excitatory and inhibitory responses, some of which are naloxone-reversible and some that are not[102–104]. The first report of the effect of an opioid in an invertebrate appears to be that of Stefano and Hiripi[105], in which they describe an increase in the intraganglionic level of DA in response to Met-Enk and Leu-Enk in *Mytilus edulis*. Naloxone blocked the effects of Leu-Enk and Met-Enk. These responses displayed a time-dependent desensitization to Met-Enk. With the freshwater bivalve *Anodonta cygnea*, Stefano and Hiripi[106] also found an increase in the DA level in the cerebral ganglia after injection of Met-Enk or morphine. Furthermore, both agents increased the levels of cyclic GMP and depressed the levels of cyclic AMP. The pharmacological effects on DA and the cyclic nucleotide levels are blocked by prior treatment of the cerebral ganglia with naloxone. The data suggest that the decrease in the cyclic AMP concentration caused by the opiates may be a result of inhibition of adenylate cyclase[107]. Aiello and Hager[108] showed that the application of morphine to the visceral ganglion of *Mytilus edulis* is cilioexcitatory to the lateral cells of the gills, and this is most likely a result of decreasing the release of DA from cilioinhibitory fibres in the ganglion. Acetylcholine (ACh) has been proposed as the excitatory neurotransmitter for stimulation of tonic contraction of the anterior byssus retractor muscle of *Mytilus*. Morphine at concentrations of 10^{-9}–10^{-4} M increased markedly the contraction induced by ACh (ref. 109).

In the snail *Helix pomatia*, a number of identified neurons regulate visceral functions, and they react selectively to Leu-Enk and morphine; some become depolarized whereas others are hyperpolarized[110]. These peptides modulate the effect of ACh and 5-HT. It is known that a combination of low molecular weight neu-

rotransmitters and peptides modulates the elementary form of learning in *Helix*, such as regulation of various rhythmic processes, including movements of the pneumostoma[111]. In this snail, Leu-Enk modulates the 5-HT effect on the habituating central neurons through a cyclic 3′-5′-AMP system both *in situ* and *in vitro*. The habituating cells are connected to the regulation of various rhythmic processes, including pneumostoma (respiratory orifice) movements. In the pteropod mollusc *Clione limacina*, sensitivity to some tactile inputs can be decreased by naloxone, and it is suggested that in these behavioural responses enkephalins mediate sensory transmission[112].

Respiration. Moroz[113] reported that 5-HT activates the respiratory rhythm in the snail *Lymnaea stagnalis*, while enkephalin acts to limit this feedback system. In the marine gastropod *Aplysia californica*, which uses gill respiration, Met-Enk inhibits gill movements[114]. Furthermore, in this species it is known that 5-HT is able to activate gill movements[115]. Dyakonova[116,117] presented clear evidence for central systemic effects of Met-Enk and 5-HT in *Helix pomatia*. She showed that Met-Enk and 5-HT are able to induce slow oscillation of the membrane potential in a group of respiratory neurons. Synchronization of the activity between the neurons in the cluster appeared to be due to an increase of electrical coupling between the cells[117]. This suggested that Met-Enk might be involved in modulation of respiratory programmes, including the central respiratory generator. For another snail, *Lymnaea stagnalis*, Moroz and Winlow[118] reported that Met-Enk inhibits the 5-HT-induced respiratory rhythm during the first few minutes after this opioid is administered. Later, Met-Enk (5–30 min after its administration) induces slow oscillation of the membrane potential in central neurons related to the respiratory programme. More recently, Dyakonova *et al.*[119] studied the effect of Met-Enk on electrical coupling between molluscan neurons, using isolated brains of *Helix* and *Lymnaea*. In the presence of both 5-HT and Met-Enk, nonrectifying electrical coupling is strongly facilitated between identified respiratory neurons in *Helix*, while coupling between 5-HT-containing ciliomotoneurons in *Lymnaea* is facilitated by Met-Enk alone. These data suggest that Met-Enk can modulate different groups of electrically coupled cells and may be involved in coordination of motor patterns[119].

Feeding. Administration of morphine resulted in significant dose-dependent increases in the ingestive responses of food-deprived slugs *Limax maximus*, and in the initiation of feeding in satiated animals[120]. These effects could be blocked by naloxone, with naloxone by itself causing a significant decrease in feeding by food-deprived slugs. These results suggest that opioids are involved in the control of feeding behaviour of the slugs.

Thermoregulation. Terrestrial snails are ectotherms, their body temperatures being dependent on the ambient temperature. The terrestrial snail *Cepaea nemoralis*, when placed on a 40°C hot plate, lifts the anterior portion of its foot. The latency of this response is affected by morphine and naloxone[121]. Administration of morphine resulted in a significant dose-dependent increase in the temperature selected by the snail in a thermal gradient. These thermoregulatory effects could be blocked and reversed by naloxone, with the opiate antagonist by itself causing a significant decrease in the preferred temperature[122]. After 6–10 days of daily administration of morphine, *Cepaea nemoralis* displayed tolerance; the effect of morphine decreased and the thermal preferences of the snails administered morphine became similar to those of saline-treated individuals. These results indicate that the opiate system plays a thermoregulatory role in molluscs. With the same species of snail, Kavaliers and Hirst[74] observed temperature responses similar to those produced by morphine when the snails were treated with Met-Enk or β-endorphin. Naloxone antagonized the effects of these peptides. Recently, Kavaliers and Ossenkopp[123] reported that repeated naloxone treatments and exposure to weak (60 Hz) magnetic fields brought about a hypoalgesic response to thermal nociceptive stimuli in *Cepaea nemoralis*.

Opioids in the aging process. Age-related changes in the opioid system of *Mytilus edulis* were detected by Stefano[124]. He studied the opioid binding profile in aging pedal ganglia. The high-affinity binding site density is significantly lower in older animals than in younger ones, whereas the low-affinity site density remains unchanged. The estimated Met-Enk and Met-Enk-Arg^6-Phe^7 levels were significantly higher for the older animals than for the younger ones. The decrease in the high-affinity binding site density and the corresponding increase in endogenous enkephalin levels suggest the existence of an opioid compensatory mechanism associated with the aging process[125].

Immune responses. Ottaviani *et al.*[126] have demonstrated that in the gastropod *Planorbarius corneus* ACTH (1–24) and β-endorphin can stimulate haemocyte locomotion and phagocytosis under stress.

Annelida

Localization and distribution

The earliest information concerning the presence of opioid peptides in annelids was produced by Alumets *et al.*[127] and Rémy and Dubois[128], who studied earthworms. Using immunocytochemistry, Alumets *et al.*[127] demonstrated the presence of immunoreactive Leu-Enk-like material in the cerebral ganglia and cerebral connectives

Table 4. Identification and localization of opioid-like peptides in annelids

Peptide	Species	Localization	Techniques	References
Leu-Enk-like	*Eisenia foetida*	Neurons of the brain	Immunocytochemistry	132
	Haemopis marmorata	Segmental ganglia	Immunocytochemistry	135, 137
	Lumbricus terrestris	Cerebral ganglia, cerebral connectives, suboesophageal ganglia, ganglia of the nerve cord, central nervous system, gut, seminal vesicle, body wall tissue, epidermis, nerve cord	Immunocytochemistry, RIA	127, 130, 133
	Nereis diversicolor	Central nervous system, peripheral nerves, oocytes, spermatocytes	Immunocytochemistry	140–144
	Theromyzon tessulatum	Central nervous system, proboscis, foregut	Immunocytochemistry	138
Met-Enk-like	*Eisenia foetida*	Neurons of the brain	Immunocytochemistry	132
	Hirudo medicinalis	Brain neurosecretory cells, fibres within the neuropil of the brain	Immunocytochemistry	136
	Lumbricus terrestris	Central nervous system, gut, seminal vesicles, body wall tissue, epidermis, nerve cord	Immunocytochemistry, RIA	130, 133
	Nereis diversicolor	Central nervous system, peripheral nerves	Immunocytochemistry	140–142
α-Endorphin	*Dendrobaena subrubicunda*	Suboesophageal ganglia	Immunocytochemistry	128
	Nereis diversicolor	Central nervous system, peripheral nerves	Immunocytochemistry	140–142
β-Endorphin	*Lumbricus terrestris*	Cerebral ganglia, cerebral connectives, suboesophageal ganglia, ganglia of the nerve cord	Immunocytochemistry	127, 131
	Nereis diversicolor	Central nervous system, peripheral nerves	Immunocytochemistry	140–142
α-Neoendorphin	*Theromyzon tessulatum*	Central nervous system, proboscis	Immunocytochemistry	138
Dynorphin	*Eisenia foetida*	Neurons of the brain	Immunocytochemistry	132
	Nereis diversicolor	Central nervous system, peripheral nerves, oocytes, spermatocytes	Immunocytochemistry	140–142
	Theromyzon tessulatum	Central nervous system, proboscis	Immunocytochemistry	138
ACTH-like	*Dendrobaena subrubicunda*	Cerebral ganglion	Immunocytochemistry	129
	Lumbricus terrestris	Epidermis, nerve cord	Immunocytochemistry	134
	Nereis diversicolor	Central nervous system	Immunocytochemistry	144
	Theromyzon tessulatum	Brain	Immunocytochemistry	139
MSH	*Lumbricus terrestris*	Epidermis, nerve cord	Immunocytochemistry	134
α-MSH	*Theromyzon tessulatum*	Brain	Immunocytochemistry	139
β-MSH	*Nereis diversicolor*	Central nervous system	Immunocytochemistry	144

RIA: radioimmunoassay.

of *Lumbricus terrestris*. They also observed in some, but not all, of the specimens immunoreactive Leu-Enk-like material in the suboesophageal ganglion and the ganglia of the nerve cord. Cells immunoreactive to β-endorphin have a distribution similar to those of the enkephalin, but differ in number and size. A summary of such localization studies[127–144] as well as distribution of opioid peptides in other annelids are presented in Table 4.

Physiological evidence for the existence of opioid receptors in the leech has been reported by Flanagan and

Zipser[137]. Homogenates of the nerve cord of the leech, *Haemopis marmorata*, display saturable binding of 3H-(D-Ala^2-)-Met-Enk.

Functions

Behaviour. Leeches respond behaviourally to externally applied morphine and to morphine injections. Kaiser[145] reported that morphine produces a biphasic hyperkinetic–quiescent locomotory response in free-swimming *Hirudo medicinalis*. Flanagan and Zipser[137] found a similar biphasic response in another leech, *Haemopis marmorata*, that was injected with morphine. Control animals injected with saline were initially hyperactive after injection, but rapidly reattached themselves to the wall of the holding tank and remained highly responsive to subsequent tactile stimulation. Morphine-injected leeches were also initially hyperactive, but after 5–10 min they fell to the bottom of the tank and remained unresponsive to all but the most extreme tactile stimulation for a period of 4 days. These animals fully recovered by day 5. This behavioural effect appears to have been due to inhibition of synaptic transmission by morphine. Gardner and Walker[146] reported an inhibitory effect of morphine on the Retzius cells of *Hirudo medicinalis*. Other evidence from *Hirudo medicinalis* and *Haemopis marmorata* suggests that the enkephalins are acting either as primary neuromodulators or as sensory neurotransmitters[147].

Feeding. Kaloustian and Rzasa[131], using radioimmunoassay found the highest concentrations of Met-Enk-like, Leu-Enk-like and β-endorphin-like material in the region of the gut which contains high digestive enzyme activity of *Lumbricus terrestris*. Isolated gut treated with these opioids showed significant decreases in its contractile properties. It appears that these opioids exert their effects by modulating the action of DA, resulting thereby in an increased transit time for food in areas of the gut with high digestive enzyme activities, hence enhancing the digestive process.

Reproduction. Experiments were done with *Nereis diversicolor* to determine whether dynorphin may have a role in the control of reproduction[144]. The basis for these experiments was the presence of this opioid in the infracerebral neurohemal area of the cerebral ganglia. Parapodia in which spermatogenesis was proceeding were incubated in sea water containing dynorphin. However, no effect on spermatogenesis was observed. Thus, it seems likely that if dynorphin-like peptides have a role in reproduction, they do not act directly on the spermatocytes, in contrast to the direct action of 'nereidin' (a brain neuropeptide that inhibits the maturation of spermatocytes in nereids)[148]. Therefore, if these dynorphin-like peptides have any role in reproduction, it is only to function as neurotransmitters to control the release of reproductive hormones.

Other invertebrates

Immunocytochemical evidence for the occurrence of opioid peptides in invertebrates other than annelids, arthropods and molluscs is rather scarce. Compounds similar to ACTH (1–39) and β-endorphin have been detected in the protozoan *Tetrahymena pyriformis*[149]. Roth *et al.*[150] reported that opioid peptides alter the feeding behaviour of the amoeba, with the response being blocked by naloxone. Venturini *et al.*[151,152] detected Met-Enk-like immunoreactivity in neuronal perikarya and in neuropil in the planarian *Dugesia gonocephala*. In this planarian naloxone induces a dose-dependent rise in the cAMP level while morphine decreases cAMP. Morphine treatment decreases the motility of this planarian whereas naloxone treatment induces screw-like hyperkinesis. Treatment with dopaminergic agonists (L-dopa, apomorphine) induces typical screw-like hyperkinesis, whereas after treatment with reserpine and haloperidol all the planarians became motionless, a response similar to that after treatment with morphine. A model for interactions between dopaminergic and enkephalinergic neurotransmission and/or neuromodulation was proposed that involved inhibitory modulation of opiates on DA release[152]. Romero *et al.*[153] reported that Met-Enk decreased the mitotic rate of adult planarians during regeneration while substance P was stimulatory. Immunocytochemical studies showed the presence of Met-Enk within the central and peripheral nervous systems of this planarian.

Piccoli *et al.*[13] made a study of the presence of endogenous Met-Enk and Leu-Enk in 11 species of marine organisms ranging from sponges to tunicates. Extracts from whole-animal tissues of the sponge *Dysidea avaria*, the cnidarians *Anemonia sulcata*, *Pelagia noctiluca*, *Rhyzostoma pulmo*, and the tunicate *Ciona intestinalis* were found to contain opioid peptides. Rémy and Brossard[154] observed immunoreactivity to Met-Enk in the cephalic nervous system of two species of nemerteans, *Lineus viridis* and *Lineus ruber*, but in the ventral ganglia, Met-Enk-like material is rather scarce. Colon-Urban *et al.*[155] suggested that endogenous opioids in various bryozoans (*Bugula neritina* and *Membranipora* sp.) play a role in the organisms' motor mechanism. Morphine inhibits tentacle activity, an effect which can be blocked by prior or concomitant naloxone application. Engbretson and Chamberlain[156] reported positive immunoreactivity to Leu-Enk in fibres of the optic medulla of the horseshoe crab *Limulus polyphemus*.

Conclusions

Although the study of endogenous opioid peptides in invertebrates is still at an early stage, the data presented in this review support the view that such molecules are present throughout the invertebrate phyla and have a

long evolutionary history. The application of immunocytochemical techniques has greatly influenced opioid research in invertebrates. Despite an impressive amount of research in invertebrates, for many of the species studied the functional significance of these opioid peptides and the mechanisms underlying their action remain elusive. The biochemical, physiological and pharmacological characterization of opioid peptides needs a careful study in order to strengthen our knowledge about their actual role in the physiology of invertebrates. Another important area that merits much attention is the identification and purification of the receptors for opioid peptides in invertebrates. Elucidation of the molecular structures of the opioid receptors will open new avenues for the evaluation of the molecular aspects of opioid receptor function.

A challenging phenomenon of current opioid research in higher animals, including mammals, is the colocalization of opioid peptides with nonopioids and classical neurotransmitters in the same nerve terminal. The rapidly increasing data on this issue show a bewildering complexity, which is presently difficult to understand in the mammalian nervous system. Simple models using invertebrates may be more suitable to unravel the nature of the putative interactions between opioid peptides and classical neurotransmitters. Finally, invertebrate opioid research may have practical applications to help control harmful organisms, such as insect pests and barnacles. Knowledge of the neurochemistry of the opioids in the invertebrates could lead to the discovery of novel ways to inhibit reproduction and growth of these organisms. If opioid peptides are important regulatory agents in metabolism, then it might be possible to devise methods of breaking particular links in the synthesis of these compounds, and research directed along these lines could provide us with much-needed compounds for the control of invertebrate pests.

Carbon dioxide and nitrous oxide in the North Indian Ocean

M. Dileep Kumar, S. W. A. Naqvi, D. A. Jayakumar, M. D. George, P. V. Narvekar and S. N. de Sousa

National Institute of Oceanography, Dona Paula, Goa 403 004, India

The understanding of biogeochemical cycling of carbon dioxide and nitrous oxide in the oceans is essential for predicting the fate of anthropogenically emitted components. The North Indian Ocean, with its diverse regimes, provides us with a natural laboratory that can unravel the mechanisms controlling these gases with implications for the global aquatic bodies. In this review we discuss the anthropogenically impinged global budgets for these gases, summarize our results, largely collected under the Global Change Programme from the North Indian Ocean and evaluate the contributions from this region to the global sea-to-air fluxes.

OVER the geological times the earth system has been at its steady course towards attaining a steady state with respect to quantities and fluxes of materials in and among various reservoirs (i.e. land, ocean and atmosphere). Man's efforts for the betterment of his living standards have led to an unprecedented interference in the natural processes of this system in recent times. The localized pollution on land or in water bodies affects the biogeochemical processes largely locally, whereas the pollutants released to the atmosphere would be of global significance.

The rising levels of gases such as carbon dioxide (CO_2), nitrous oxide (N_2O), methane (CH_4) and freons (chlorofluorocarbons) in the atmosphere have been recognized not only to change the natural balances of carbon and nitrogen but also affect climate and human health[1]. The accumulation of these gases in the atmosphere enhances the greenhouse effect by absorbing the infrared radiation and leads to stratospheric ozone depletion. Nitrous oxide is 200 times more effective as a greenhouse gas, on per mole basis, compared to CO_2, but, due to a much lower concentration, it accounts for only about 5% of the total warming effect[2]. Under the International Geosphere–Biosphere Programme (IGBP) 'A study of global change', a lot of studies are being carried out globally on biogeochemical processes involving the greenhouse gases. We provide here a synthesis of the available data on CO_2 and N_2O cycling in the North Indian Ocean, largely generated as a result of our participation in the IGBP, in the context of global biogeochemical cycles.

Global balance of impinged CO_2 and N_2O

The atmospheric CO_2 and N_2O concentrations are increasing at annual rates[2] of 0.5% and 0.2%, respectively. The major anthropogenic activities contributing to the observed increases are fossil fuel combustion, use of fertilizers and deforestation. Of the total CO_2 released (7.3×10^3 Mt C yr^{-1}), 3.4×10^3 Mt C yr^{-1} is accumulating in the atmosphere whereas 2×10^3 Mt C yr^{-1} is being removed by the oceans[3] (Figure 1 *a*). However, there is considerable controversy regarding the amount associated with deforestation (1.9×10^3 Mt C yr^{-1}), which at present is attributed to an unknown sink or unaccounted recycled carbon accumulation in soils[3]. The increase in carbon fixation on land, due to the use of nitrogen fertilizers, has not so far been included in the carbon budget. It may account for the missing carbon to some extent. For instance, the agricultural nitrogen fixation in 1974 is estimated[4] to be about 39 Mt N yr^{-1}; this accounts for 0.65×10^3 Mt C yr^{-1}, with a C:N ratio of 19:1 for terrestrial plant material. Thus, this increased carbon fixation could roughly account for at least 34% of the presently missing carbon.

The land-to-air fluxes of N_2O (Figure 1 *b*) are essentially closer to the lower ranges given by Yoshinari[5] (cultivated soils, fertilized soils, unfertilized soils, tropical forests and temperate forests account for 2.0, 3.0, 4.5, 5.8 and 3.0 Mt N yr^{-1}, respectively), to which the flux (0.03 Mt N yr^{-1}) from watershed regions[6] was added in this attempt. The fossil fuel combustion and

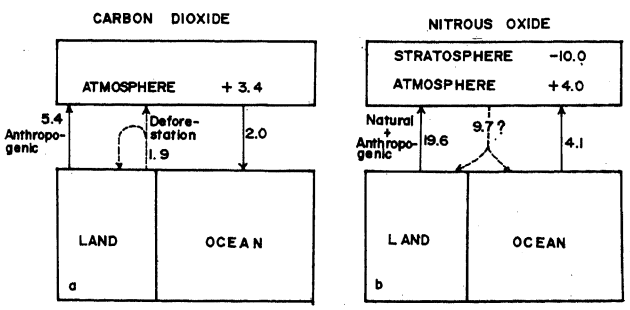

Figure 1. Global budgets for: *a*, anthropogenic component (only) of CO_2; and *b*, human-influenced total N_2O. CO_2 figures are in Gt C yr^{-1} (10^{15} g C yr^{-1}) and those of N_2O are in Mt N yr^{-1} (10^{12} g N yr^{-1}).

biomass burning contribute[7] 0.5 and 0.3 Mt N yr^{-1}, respectively, wherein nylon production results in an emission[8] of 0.42 Mt N yr^{-1}. We evaluated the fluxes from coastal wetlands and marshes to be 0.1 Mt N yr^{-1} based on the data of de Angelis and Gordon[9]. The upwelling zones gives a flux[10] of 1.0 Mt N yr^{-1} while the open ocean gives at least 3.0 Mt N yr^{-1}, which is closer to that given by Yoshinari[5], though the values in the literature vary over a wide range (1–44.5 Mt N yr^{-1}). The only known sink for N_2O is its photolytic decomposition in the stratosphere (Figure 1 *b*). After accounting for its stratospheric loss and atmospheric accumulation, we find that about 9.7 Mt N yr^{-1} is not balanced (Figure 1 *b*). This reveals that either the fluxes, especially from land, are overestimated or there could be an unknown sink, as in the case of carbon, but which is unlikely.

The unique North Indian Ocean

The presence of the Asian landmass, which bounds the Indian Ocean at relatively low latitudes, makes the North Indian Ocean geographically distinct. The Indian peninsula bifurcates the North Indian Ocean into two hydrographically and climatologically different water bodies – the Arabian Sea and the Bay of Bengal. The Arabia Sea occupies an area of 6.225×10^6 km^2 while the Bay of Bengal covers 4.087×10^6 km^2, excluding the Laccadive and Andaman seas. Seven major rivers flow into the Bay of Bengal (Brahmaputra, Ganges, Irrawady, Godavari, Mahanadi, Krishna and Kaveri) whereas three pour into the Arabian Sea (Indus, Narmada and Tapti). These rivers carry 1625×10^9 and 301×10^9 m^3 yr^{-1} of fresh water and 1387×10^6 and 195×10^6 tons yr^{-1} of suspended solids, respectively, into the Bay of Bengal and the Arabian Sea[11]. In addition to the smaller run-off, excess evaporation in the Arabian Sea leads to a negative water balance[12].

The North Indian Ocean is among the more productive parts of the oceans with a surface production (upper 1 m layer) amounting to 112 Mt C yr^{-1} (ref. 13). The productivity is particularly high in the Gulf of Oman and off the coasts of Arabia, Somalia and Southwest India in the Arabian Sea and off the Southeast Indian Coast, Visakhapatnam, Sri Lanka and Burmese coasts in the Bay of Bengal. An anomalous feature of the oceanography of the Indian Ocean is that the zones of intense upwelling occur not along the eastern boundary, as happens in the Pacific and the Atlantic Oceans, but in the northwestern parts off the Somali and the Arabia coasts. Consequently, the column productivity in the Arabian Sea is much higher compared to that in the Bay of Bengal. The high productivity causes intense oxygen demand in the subsurface layers. Due to this, the water column in the Arabian Sea experiences severe oxygen depletion, resulting in the onset of reducing conditions, thus making the North Indian Ocean one of the most important denitrification sites[14–18] in the world.

Carbon dioxide in the North Indian Ocean

A higher rate of biological production in the Arabian Sea compared to that in the Bay of Bengal coupled with the different hydrographies of the two regions causes vast differences in the biogeochemical cycling in subsurface waters. Although the entire North Indian Ocean experiences a severe oxygen depletion at mid-depths, the oxygen minimum layer is not only much more thicker in the Arabian Sea but is also far more intense. Consequently, while the Arabian Sea experiences denitrification within a large volume of intermediate waters, the Bay of Bengal is not an active water column denitrification site[18]. Denitrification is the most intense in the northeastern and central parts of the Arabian Sea. An intermediate particle maximum (as inferred from the vertical profiles of the beam attenuation coefficient,

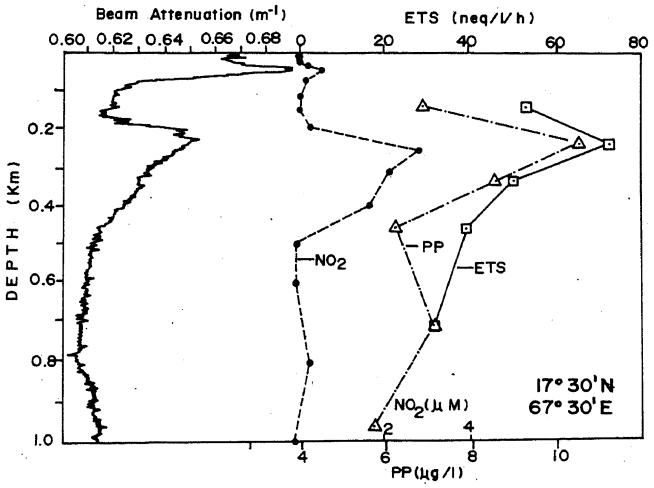

Figure 2. Profiles of beam attenuation coefficient (BAC), nitrite (NO_2^-), particulate protein (PP) and electron transport system (ETS) activities at a station in the central Arabian Sea.

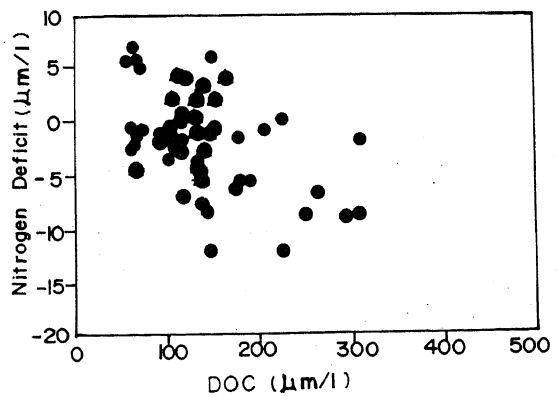

Figure 3. Relation between dissolved organic carbon (DOC) and nitrate deficit in the Arabian Sea.

BAC) has been found[19] to be associated with denitrification in the Arabian sea; particulate protein (PP) and activity of the respiratory electron transport system (ETS) also showed maxima (Figure 2; data collected during February 1992 on FORV Sagar Sampada Cruise 98) within the denitrifying layer. The raining particulate organic carbon from the overlying waters seems to be insufficient to support the measured metabolic rates, thus underscoring the role of organic carbon supplied through lateral processes in fuelling subsurface respiration within the oligotrophic central regions of the Arabian Sea[19]. This view is augmented by the observed negative relation[20] between DOC and inorganic nitrate deficits (Figure 3). The DOC levels are lower in the north than in southern Arabian Sea probably owing to the faster utilization and turnover of this form of carbon. Consequently, the total carbon dioxide (TCO_2) is also found to be inversely related to the DOC in the Arabian Sea[20].

In the subsurface layers the TCO_2 is higher in the North than in the South Arabian Sea because of the increased respiration rates in the northern region and also due to the aging of waters as they move northward. In the Bay of Bengal, on the other hand, there occur negligible north–south gradients in TCO_2 and O_2, presumably due to a much lower rate of organic decomposition within the water column from a combination of lower biological productivity and rapid settlement of organic matter through the water column, consequent to its incorporation into rapidly sinking terrigenous material. The increase in TCO_2 with depth is due to the decomposition of organic and inorganic materials. Surprisingly, in spite of the differences in productivity between the Arabian Sea and the Bay of Bengal and the rapid settlement of organic matter in the latter region, the levels of TCO_2 are almost the same (Figure 4 *a*,*b*). Sinking fluxes of organic matter ranged between 2.04 and 3.59 g C m^{-2} yr^{-1} in the Bay of Bengal[21], while they varied from 1.53 to 1.80 g C m^{-2} yr^{-1} in the Arabian Sea[22]. These differences, due to organic matter decomposition, could be balanced by increased contribution of skeletal dissolution to TCO_2 in the Bay of Bengal deep waters. Approximately 40–50% of the TCO_2 difference (at depths >1 km) between latitudes 10° and ~20°N in the Arabian Sea is accounted for by skeletal dissolution, but this mechanism is responsible for ~85% of TCO_2 increase between latitudes 11° and 18°N in the Bay of Bengal[23]. The prevailing reducing conditions lower the pH levels in the Arabian Sea as compared to those in the Bay of Bengal. As a result, the intermediate waters in the former region are more corrosive to skeletal carbonate materials than those in the latter[23]. Interestingly, skeletal dissolution is relatively more in the north and eastern parts than in the south and western regions of the Arabian Sea[24].

The pH within the oxygen minimum zone is generally lower than in other layers and hence the carbonate

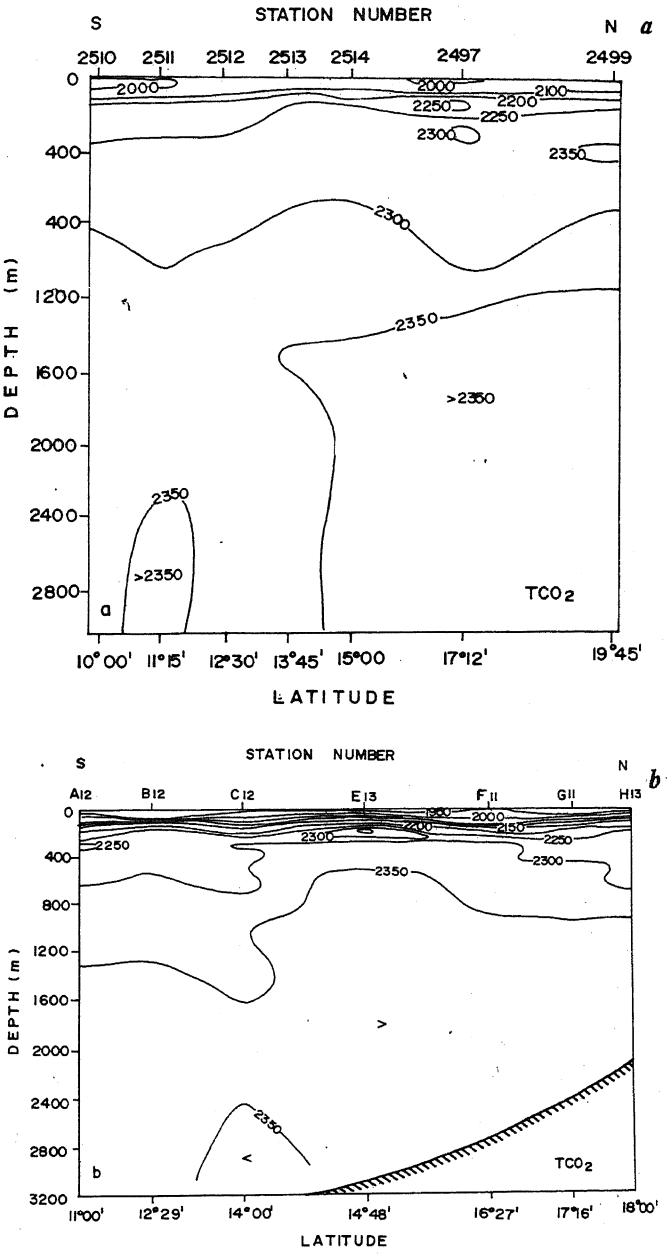

Figure 4. Distribution of total CO_2 (μM) in: *a*, Arabian Sea; *b*, Bay of Bengal.

equilibrium tends to shift relatively more towards the formation of carbonic acid. This increases the partial pressure of CO_2 (pCO_2) in this zone, although the TCO_2 concentrations are higher in the deep and bottom waters than in the oxygen-minimum zones (Figure 5 *a*,*b*). As the pH is considerably lower in the Arabian Sea than in the Bay of Bengal, the computed pCO_2, based on pH and TCO_2, is relatively higher in the former region[23]. A maximum pCO_2 of 1200 μatm occurs in the oxygen-minimum zone of the central Arabian Sea while it is 1100 μatm in the central Bay of Bengal. The pCO_2 is higher by about 100 μatm at any depth in the Arabian Sea than in the Bay of Bengal.

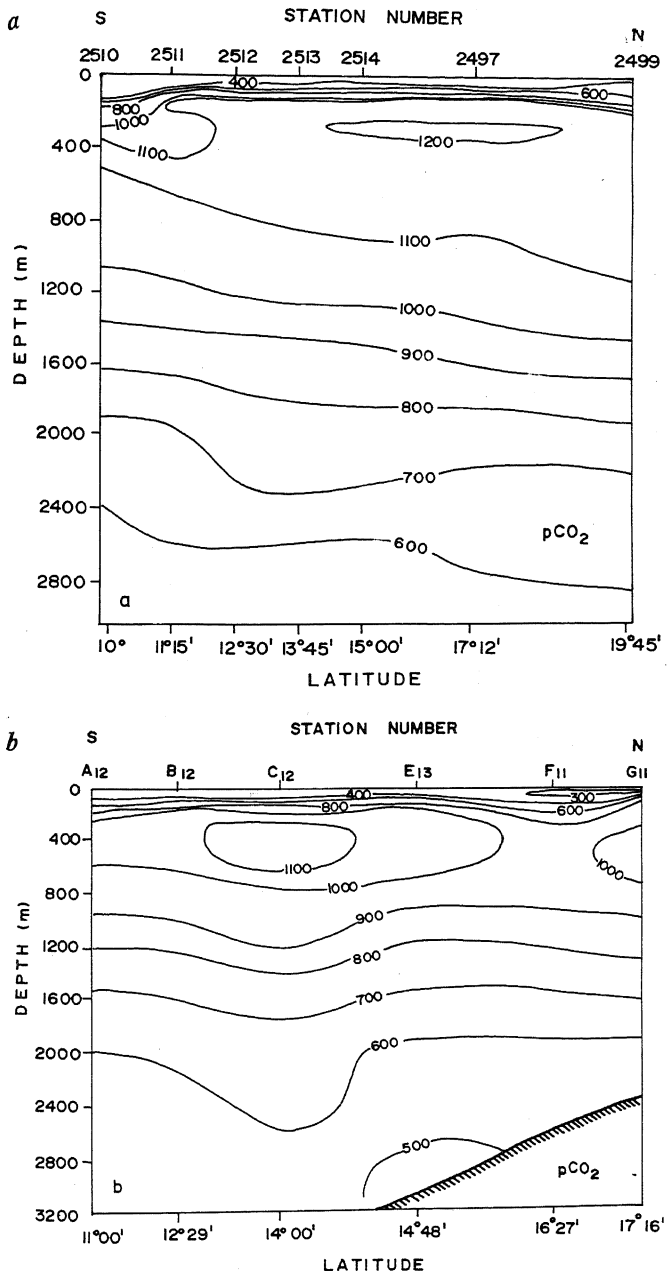

Figure 5. Distribution of pCO_2 (μatm) in: *a*, The Arabian Sea; *b*, Bay of Bengal.

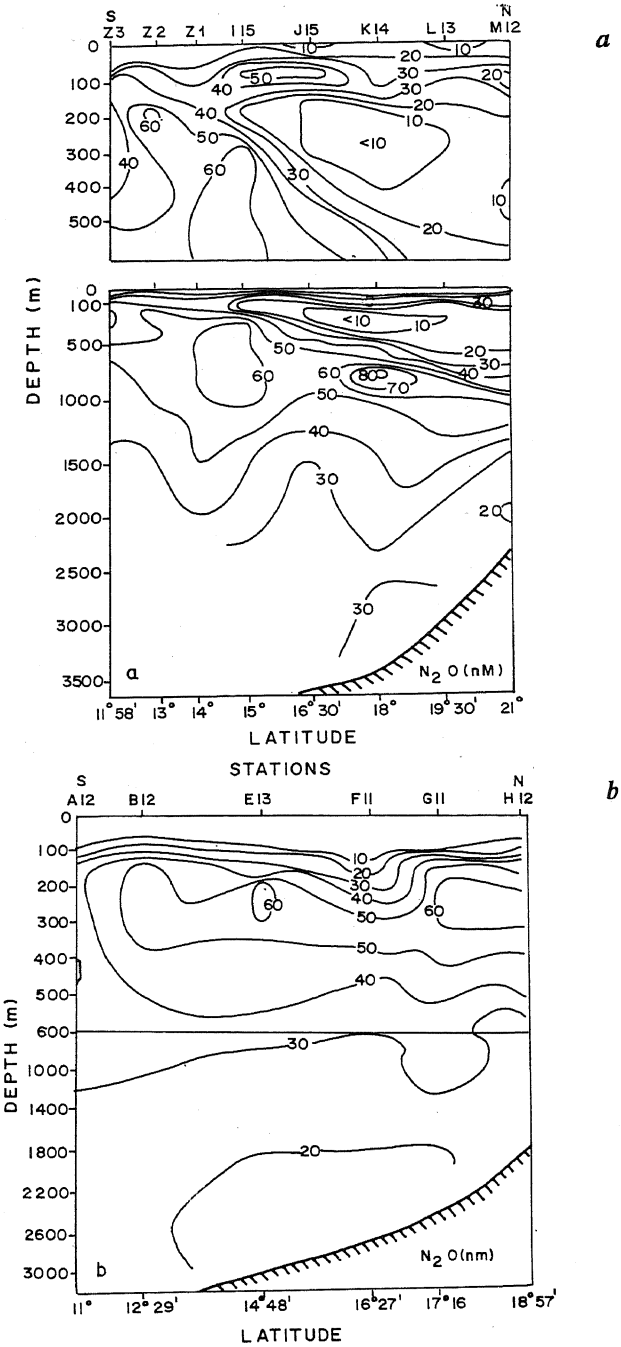

Figure 6. Nitrous oxide (nM) distribution in: *a*, The Arabian Sea; *b*, Bay of Bengal.

Nitrous oxide in the North Indian Ocean

Vertical profiles of N_2O generally exhibit maxima within the oxygen-minimum zones. The most significant point revealed by Figure 6 (data from ref. 25) is the occurrence of double maxima in N_2O with a minimum in the intensely reducing intermediate waters of the north-eastern Arabian Sea[25,26]. Outside the denitrification zone, N_2O exhibits a single peak coinciding with the oxygen minimum[25,27]. Consumption of N_2O within the strongly reducing zones appears to produce the minimum in N_2O within the denitrifying zone of the north-eastern Arabian Sea, while the maxima in N_2O occur at the boundaries of this zone, particularly at the lower boundary with concentrations as high as 80 nM (Figure 6 *a*). The N_2O concentrations increase in the northward direction (Figure 6 *b*) in the Bay of Bengal, with a maximum of 80 nM (occurring to the west of the transect shown in the figure). Maximum in the north corresponds to oxygen minimum. Although very low levels of oxygen are observed in subsurface layers of the northernmost Bay of Bengal, the absence of a secondary nitrite shows that denitrification may not occur within the water column in this region. The occurrence of strong

sources and sinks of N_2O in close proximity to each other is expected to lead to a very rapid turnover of N_2O in this region, which may have important implications for the residence time and isotopic composition of oceanic N_2O. The relations between apparent N_2O production and the apparent oxygen utilization are positively linear in different depth ranges in the Arabian Sea[25] and the Bay of Bengal[27]. The slopes estimated for the Arabian Sea are higher than those for the other oceanic regions, implying that the rate of N_2O production in this region is much higher[25]. Based on the horizontal gradients and that expected from oxygen utilized, significant quantities of N_2O are expected to be consumed within the sediments[25,27].

The enhanced production of N_2O in the subsurface layers leads to large vertical gradients within the upper thermocline and the consequent large fluxes into the surface layers through eddy diffusion. The Arabian Sea surface waters are relatively more supersaturated (average of 186%; refs 25, 26) as compared to those in the Bay of Bengal (125%; ref. 27). This higher saturation is related to higher vertical diffusion coefficients in the Arabian Sea (0.55 $cm^2 s^{-1}$; ref. 25) than in the Bay of Bengal (0.16 $cm^2 s^{-1}$; ref. 27), in the thermocline region. The suppressed vertical mixing in the Bay of Bengal is caused by strong thermohaline stratification caused by river run-off.

Sea-to-air fluxes in the North Indian Ocean

The differences between the concentrations observed at sea surface and those expected from the solubility calculations, based on the abundance of these gases in the atmosphere, determine the magnitude and direction of gas fluxes between the atmosphere and the sea. The abundance of N_2O and pCO_2 in surface layers will be governed by the gradients in these properties below the surface mixed layer and the rate of vertical mixing. The levels of pCO_2 (Figure 5) and N_2O (Figure 6) are higher within the oxygen-minimum zones in the North Indian Ocean sustaining large upward fluxes of these gases across the thermocline.

The fraction of CO_2 in air, in equilibrium with surface waters, over the Arabian Sea is calculated to be >0.6, which increases northward[24]. This also indicates that the Arabian Sea acts as a source of CO_2 to the atmosphere, in accordance with the earlier predictions[28–30]. The higher pCO_2 gradient between the deep and surface layers in the Arabian Sea than that in the Bay of Bengal (Figure 5) results in higher average exchange rates in the former region (2.0 mmol $m^{-2} d^{-1}$) than in the latter (0.17 mmol $m^{-2} d^{-1}$); here an atmospheric CO_2 of 350 µatm was used. Within the Arabian Sea the fluxes are higher in the north than in the south. The overall atmospheric fluxes of CO_2 are much larger from the Arabian Sea (55 Mt C yr^{-1}) compared to those from the Bay of Bengal (3 Mt C yr^{-1}). This difference arises from a combination of lower pCO_2 gradient, lesser vertical diffusion coefficients and smaller area of the Bay of Bengal.

A high degree of supersaturation of N_2O in the surface waters of the North Indian Ocean results in significant evasion of this gas to the atmosphere. As in the case of CO_2, the N_2O in surface layers is also controlled by upward diffusion from the subsurface layers. The average emission rates for this gas are 4.46 µmol $m^{-2} d^{-1}$ in the Arabian Sea and 0.65 µmol $m^{-2} d^{-1}$ in the Bay of Bengal. These rates amount to N_2O fluxes of 0.28 and 0.03 Mt N yr^{-1} from the Arabian Sea and the Bay of Bengal, respectively[25,27]. Hence, relatively large amounts of these greenhouse gases are emitted from the former region than from the latter.

Budgets for CO_2 and N_2O in the North Indian Ocean

In order to understand the biogeochemical cycling of an element it is essential to quantify its fluxes between various major reservoirs as well as between various compartments within a reservoir. The situation in the

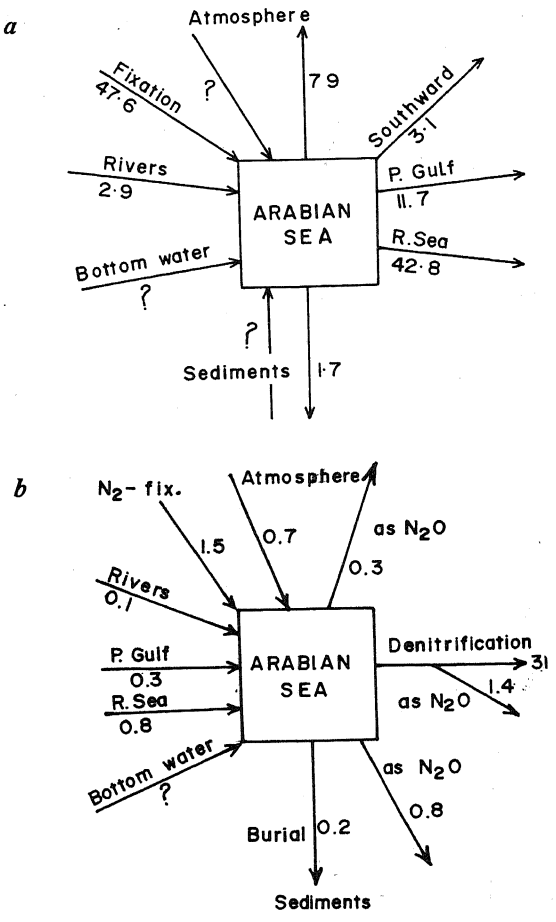

Figure 7. Budgets for: *a*, carbon; *b*, nitrogen (including N_2O) in the Arabian Sea.

Indian Ocean is complicated by the presence of marginal water bodies that continuously exchange water and solutes with the Arabian Sea and with river run-off that brings in enormous amounts of inorganic and organic substances into the Bay of Bengal. Recently, attempts have been made to quantify the fluxes between various reservoirs in the Arabian Sea[30,31]. Figure 7 depicts the estimated net carbon and nitrogen fluxes into and out of the Arabian Sea. The flow of carbon into the Arabian Sea from the rivers is the only estimated external input (using an annual discharge rate of 238 km^3 and an average HCO_3^- concentration[32] of 12 mg C l^{-1}), which is close to that (2.3 Mt C yr^{-1}) evaluated earlier[30]. The unknowns are its influx from the atmosphere, inflow from the south of equator and upward diffusion of regenerated CO_2 from the sediments. The biologically fixed carbon transported to subsurface Arabian Sea layers, through sinking of particulate organic material, is estimated[31,33] to be about 47.6 Mt C yr^{-1}. The estimated fluxes (Figure 7) reveal that the Arabian Sea serves as a source of CO_2 to the atmosphere and the surrounding bodies, the Persian Gulf and the Red Sea. Carbon is also supplied to the underlying sediments and to some extent to the South Indian Ocean. These estimates indicate that the Arabian Sea is constrained by a CO_2 deficit of ~88 Mt C yr^{-1}. In order to maintain the CO_2 in the Arabian Sea at steady state, this amount must be supplied from the south, through the inflowing bottom water, and from the atmosphere.

As our state of understanding of the processes regulating N_2O in the Arabian Sea is still rudimentary, it is difficult to work out the budget for this gas. Figure 7 shows the net fluxes of N_2O together with those of nitrogen[25,30,31,33]. In contrast to their negative contribution to CO_2, the Persian Gulf and the Red Sea act as net sources of nitrogen to the Arabian Sea. The losses of nitrous oxide from the Arabian Sea amount to 2.5 Mt N yr^{-1}. Hence, the Arabian Sea should produce an equal amount annually.

The estimated carbon fluxes into the confluence zones of the rivers Ganges and Brahmaputra are 14.6 Mt C yr^{-1} and 17.1 Mt C yr^{-1}, respectively[34]. The carbon input through dissolved and particulate organic forms from the Ganges amounts[34,35] to 1.5–2.0 Mt C yr^{-1}. The Bay of Bengal serves as a mild source of atmospheric N_2O and CO_2 during the southwest premonsoon[23,27] but as a sink for CO_2 during the northeast monsoon[36].

Contribution of the North Indian Ocean to global air–sea fluxes

The contribution of the North Indian Ocean to the global sea-to-air flux[2] of CO_2 of 90 Gt C yr^{-1} appears to be small (0.06 Gt C yr^{-1}). However, it amounts to about 5% of the efflux from global equatorial oceans. On the contrary, the N_2O emission from this region is globally significant as it is about 8% of the estimated atmospheric input from the oceans. However, the region under study is significantly influenced by the highly variable monsoonal winds and intermittent cyclones. The transfer velocities of gases across the air–sea interface increases with increase in wind velocity. These transfer velocities have been computed to be enhanced seven times during the monsoon season compared to those during the non-monsoon seasons[37]. However, all the estimates made so far, including those for global fluxes, are derived from observations made during the calm seasons and do not consider the stability of sea surface as well as contributions from bubbles, and, hence, should be considered as underestimates. Further, the Arabian Sea experiences strong upwelling seasonally associated with the monsoons. Hence, the dynamics of these gases need to be studied in detail in order to make more accurate estimates of sea-to-air fluxes from this most dynamic region of the world oceans.

We present here a novel opto-electronic technique to directly measure the internal wave oscillations, created by systematically disturbing a density stratified water column with a rotating propeller in a laboratory wave tank. The technique, based on the principle of laser beam deflection (LBD), apart from being noninvasive and highly sensitive, does not have the customary constraints on the sampling frequency and the duration of data sampling, as is the case with conventional experimental procedures. The noninvasive nature of this technique has good potential in future studies of diffusion and mixing processes in different disciplines.

INTERNAL waves in the ocean are ubiquitous, being associated with wind and air pressure fluctuations, changes in ocean floor topography, wakes of moving bodies and instabilities in the water body. Studies on internal waves enable a better understanding of the various mixing processes in the ocean, which result in the redistribution of momentum, temperature (heat) and salinity, responsible for climatic changes and, nutrients responsible for biological productivity. The oceanic internal waves occupy a vast continuum of spatial and temporal scales[1]. Available data on oceanic motions suggest horizontal scales ranging from a few tens of meters to a few kilometers and temporal scales ranging from the inertial period f^{-1} (order of magnitude in days), to the Brunt Vaisala period N^{-1} (order of magnitude in minutes).

Internal wave measurements

To the best of our knowledge, only indirect eulerian field of internal waves were measured by monitoring a closely related physical parameter like temperature or current velocity. Lagrangian field measurements of internal waves involve neutrally buoyant floats that are tracked, or sensor arrays towed horizontally through water. The literature[2–6] points out the limitations of the indirect eulerian measurements, whereas the established Lagrangian techniques are constrained by the uncertainties in understanding the underlying physics[7].

The electrical conductivity of salt water in the ocean was earlier considered to provide a convenient way of

measuring density in a stratified fluid. In this technique, the total impedance between a relatively large fixed electrode and a much smaller, movable platinum electrode is measured in an A.C. bridge network. However, two difficulties are encountered in practice. First, the probe impedance tends to drift with time. Second, time response of the probe is limited, roughly by the time required to convect material across the probe volume[8].

Remote sensing of oceanic internal waves from airborne synthetic aperture radar (SAR) imagery, a state-of-art measurement technique, involves intricate calibrations and signature extraction techniques. As the patterns on SAR imagery caused by mesoscale oceanic features are only a surface manifestation of subsurface physical processes, it is imperative to develop a robust theoretical model which links the subsurface processes to SAR-observed surface patterns. Both the manner in which SAR data are calibrated and the techniques used to extract the signatures associated with the surface patterns of interest can significantly influence the magnitude and structure of the SAR signature[9].

Laboratory investigations of internal waves primarily utilize noninvasive flow visualization techniques, as *in situ* monitoring of the complex internal wave dynamics is difficult[8]. Though flow visualization techniques give a comprehensive picture of the processes involved, they are primarily qualitative in nature. Flow visualization techniques are broadly subdivided into those that make use of light scattered by tiny particles in the fluid and those that make use of variations in the refractive index. Among the former, laser Doppler anemometry is now a standard means of obtaining fluid velocities. The fluid velocity can be measured with a high degree of accuracy as a function of time but only at a single point in the fluid at any given time[10]. Although, recent studies have shown that the instantaneous velocity field over a complete plane of interest in the fluid is now possible with speckle photography, the potential applications to fluid mechanics have not yet been fully explored.

Of the methods making use of refractive index variations, the laser beam deflection (LBD) or the mirage effect has been increasingly used in recent years for various applications[11,12], in which, the optical probe beam deflection due to an *artificially* generated refractive index gradient (RIG) is generally monitored.

Novel opto-electronic technique to monitor internal waves

Internal waves in a stratified fluid involve changes of refractive index across the field to be investigated, which may be visualized or photographed using optical methods that depend on the effects of the refractive index changes on the transmission of light. Several techniques are available of which the Schlieren techniques have been extensively used. The main use of Schlieren and direct shadow methods is to show the position and shapes of regions of density changes, such as those occurring in high speed flows, mixing problems and problems of free and forced convection.

Concept

In this section we present a novel optical technique, based on the principle of LBD, to directly quantify internal waves in the laboratory, generated by the rotating propeller of a self-propelled body submerged in a stratified water column.

In an inhomogeneous medium as in the presence of internal waves in a stratified water column, a laser beam gets deflected because of the *naturally* occurring, time-varying changes in the density of the medium (and therefore, the RIG) at a particular location. For laser beams with a gaussian intensity profile, the output voltage change monitored by a small area photo detector system is closely related to the changes in beam deflection[13]. Using this principle we were able to directly monitor internal waves generated by the rotating propeller of a stationary body placed inside a 6 mm thick perspex tank (1.8 m × 0.3 m × 0.5 m) containing an exponentially stratified salt water column.

The technique depends on the deflection of a ray of light from its undisturbed path when it passes through a medium in which there is a component of the gradient of the refractive index normal to the ray. The deflection of light ray is a measure of the first derivative of density with respect to the distance, i.e. the density gradient and therefore, it can be shown that the curvature of the ray is proportional to the refractive index gradient normal to the ray. If the Y axis is taken in the direction of the undisturbed ray, the curvatures in the XY and ZY planes respectively are given by

$$\frac{\partial^2 x}{\partial y^2} = \frac{1}{\mu}\frac{\partial \mu}{\partial x}. \qquad (1)$$

$$\frac{\partial^2 z}{\partial y^2} = \frac{1}{\mu}\frac{\partial \mu}{\partial z}.$$

If the total angular deflections in the XY and ZY planes are denoted by ε'_x and ε'_z respectively, then

$$\varepsilon'_x = \int \frac{1}{\mu}\frac{\partial \mu}{\partial x}\mathrm{d}y, \qquad (2)$$

$$\varepsilon'_z = \int \frac{1}{\mu}\frac{\partial \mu}{\partial z}\mathrm{d}y.$$

If the optical disturbance is in the working section of the wave tank, the ray of light will be deflected on leaving the tank so that

$$\mu \sin \varepsilon' = \mu_0 \sin \varepsilon, \qquad (3)$$

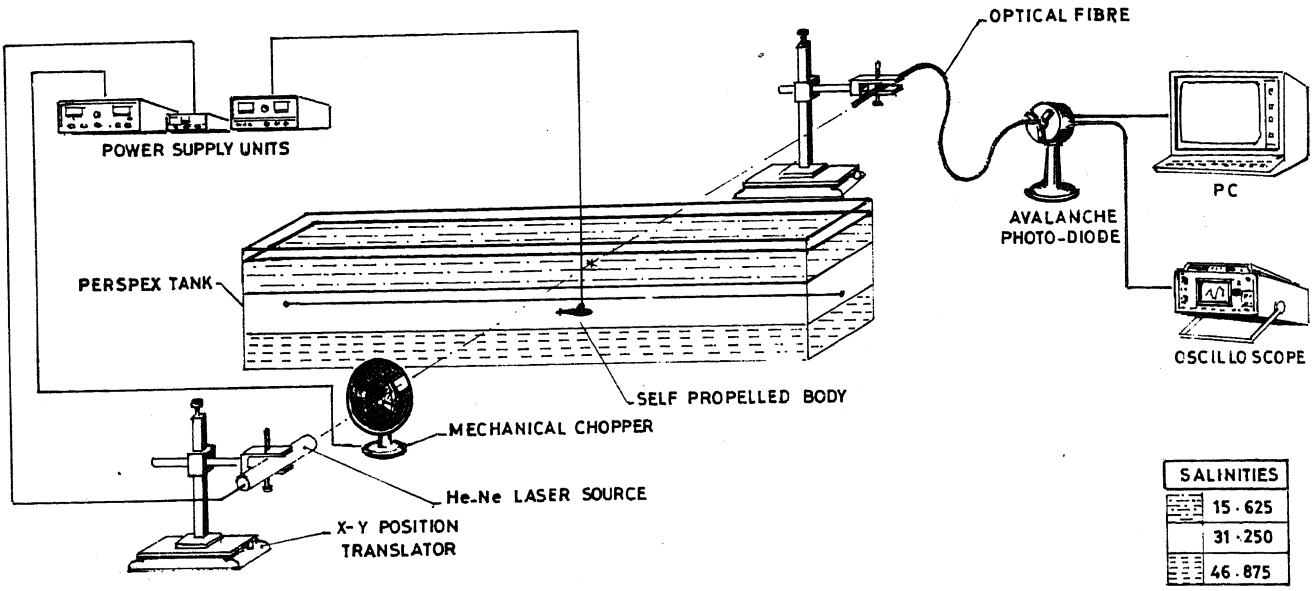

Figure 1. Schematic diagram of the experimental set-up to monitor internal waves in a stratified fluid employing the laser beam deflection technique.

where μ_0 is the refractive index of the air surrounding the tank, and μ is the refractive index in the working section. Thus, the final angular deflection ε measured beyond the tank is given by

$$\varepsilon_x = \frac{1}{\mu_0}\int \frac{\partial \mu}{\partial x}\,dy, \qquad \varepsilon_z = \frac{1}{\mu_0}\int \frac{\partial \mu}{\partial z}\,dy, \tag{4}$$

where the integrals are taken over the width of the working section. In the case of two-dimensional flow in a wave tank of width L these expressions simply become

$$\varepsilon_x = \frac{L}{\mu_0}\frac{\partial \mu}{\partial x}, \qquad \varepsilon_z = \frac{L}{\mu_0}\frac{\partial \mu}{\partial z}, \tag{5}$$

the deflections being in the direction of the RIG, i.e. towards the region of higher density.

The noninvasive nature of this technique has potential application in the study of diffusion and mixing processes in different disciplines, especially biofluid mechanics. The technique can be adapted for oceanographic field applications.

Laboratory studies

Experimental set-up. An intensity stabilized 5 mw, He–Ne continuous-wave laser beam (half power beam width of 0.84 mm) was used as the probe. The deflections of the probe beam caused by the induced RIG in the medium were detected by a position sensitive detector (PSD). The polished tip of a multimode optical fibre (80/120 μm) served as the sensor head of the PSD. The other end of the optical fibre was coupled to an avalanche photodiode (APD, *Thorn EMI* make), which was incorporated into an appropriate detector circuit of very low noise level. The output voltage from the APD circuit is piped into a personal computer using a high speed analogue to digital conversion data acquisition card. The resolution of the analogue to digital voltage conversion was 0.0024414 V. As the probe beam is continuous, the sampling frequency and duration of the data sample can be chosen without any constraints. The experimental set-up is shown in Figure 1.

Prior to each experiment, a mechanical chopper placed between the laser source and the tank was used to maximize the output signal by properly aligning the probe beam and the PSD. During the actual experiments, however, the chopper was removed. Initially, experiments were carried out to ascertain that temporally and spatially varying beam deflections occur only due to changes in the RIG of the medium in the wave tank, but not due to the RIG at the air–perspex–water interfaces. Hence, the time-varying beam deflections or changes in the output voltages can be attributed to the internal wave (density) fluctuations, generated by the propeller motions of the stationary body inside the stratified water column.

Calibrations. Utilizing known density samples in the perspex tank, the output voltages of the laser beam propagating through the samples were monitored. An output voltage of 3.62 V was observed for a sample density of 1.0043 g/cc and an output voltage of 1.08 V

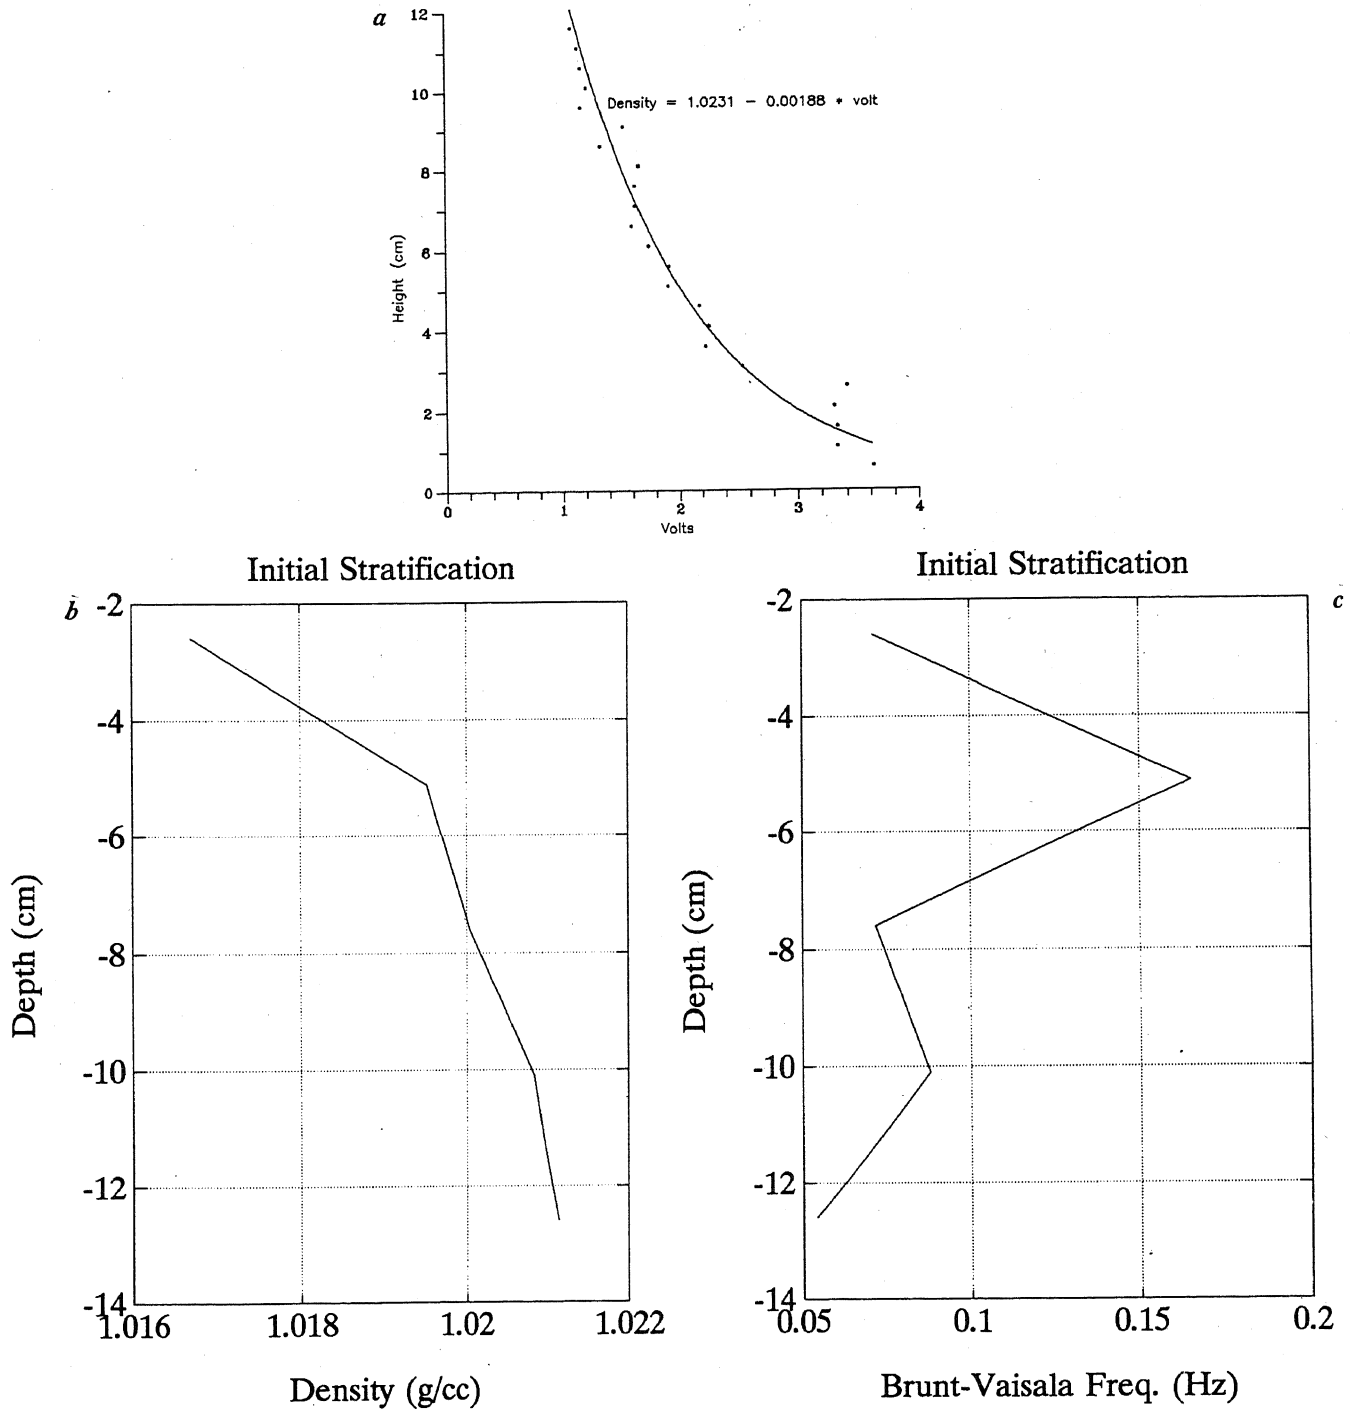

Figure 2. Initial output voltage distribution (*a*), calibrated density stratification (*b*), and the associated Brunt-Vaisala frequency [$N(z)$] profile (*c*), in the laboratory tank before the start of the experiment, where $N^2(z) = g/\rho_o\{\partial\rho/\partial z\}$.

was observed for a sample density of 1.0231 g/cc. Initially, a step-distribution was obtained by sequentially introducing the bottom layer (1.0231 g/cc), the middle layer (1.0113 g/cc) and the top layer (1.0043 g/cc) into the tank. Before introducing the middle and top layers, a wax paper was stretched on top of the water in the tank and the next layer added, after which the wax paper was rolled up from one end of the tank ensuring minimal disturbance. Molecular diffusion was allowed to take place for about a day, which resulted in the exponential distribution.

The output voltages of the laser beam propagating at different levels of the tank, in the vertical direction were monitored. Figure 2 *a* shows the vertical profile of output

voltages approximately a day after introducing the three layers in the tank. The exponential distribution is an artifact of the molecular diffusion. The calibration constants were obtained after solving the simultaneous (straight line) equations relating density and voltage. The gain and offset calibration constants were found to be 0.00188 and 1.0231 respectively. Figures 2 *b* and 2 *c* show the corresponding density and Brunt-Vaisala distributions in the tank. The output voltage from the APD circuitry which is piped into the PC as digital data is finally calibrated as density fluctuations.

Experiments. At the start of each experimental run the propeller was switched on. The sampling frequency was chosen as 100 Hz. In order to avoid reflections from the end walls of the tank, the duration of sampling for each run was limited to 2 min, the monitored travel times of hydrodynamical signatures from source to the end wall being greater than 2 min. Four major experiments covering 80 data runs in total were conducted with the laser source-detector system and the stationary body with its rotating propeller placed at different positions, for the same stratification. Detailed studies on different aspects of internal wave dynamics and mixing are being reported elsewhere. In this article, however, we present data from one of the typical experiments. During this experiment, time series observations of density fluctuations were monitored at 24 different locations along the wall of the tank forming a vertical array of time series observations as shown in Figure 3. In this article, however, data from the first vertical array of observations are only being reported. For all the observations, the position of the stationary body with its rotating propeller was fixed and only the position of the laser source-detector system was varied. Before each observational run, the propeller was switched on and after each observational run of 2 min duration, the propeller was switched off, allowing the water to settle down to its equilibrium position. As the forcing imparted to the water inside the tank was not strong (just sufficient to create internal wave fluctuations only) it is assumed that the mixing created by propulsion of the stationary body does not alter the characteristics of the stratified water column in the tank in a significant manner. The wake generated by a submerged body moving through a density-stratified medium is a turbulent region of mixed fluid of homogeneous density. The observations of earlier researchers that due to the stabilizing effect of the stratification, turbulence near the wake boundary is rapidly damped and does not cause appreciable mixing of the fluid with its surroundings, give ample support to our assumption. Therefore, as the mixed fluid seeks to return to its equivalent density level, the region collapses vertically and internal waves are consequently generated. At each location, the mean density value obtained during calibration experiment was deducted from the time series observations at that location to ensure that the observations reflect the actual density fluctuations caused by internal wave dynamics.

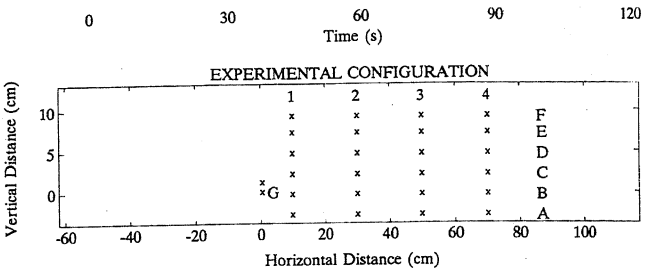

Figure 3. Experimental configuration. The crosses denote the exact locations where measurements were made. The *X*-direction is denoted by 1, 2, 3 and 4. The *Z*-direction is denoted by A, B, C, D, E and F. The propeller (origin) was lying 0.5 cm to the left of G.

Conventional Schlieren techniques – Limitations

Our technique is similar in principle to the Schlieren system[14,15]. However, the primary difference is that a conventional Schlieren system enables only qualitative flow visualization based on frame-to-frame observations, whereas our technique provides quantitative point-probe diagnostics continuously.

Conventional Schlieren techniques tend to become ineffective in monitoring smaller density changes of a medium. Indeed, when the density changes are very low (as in our study), conventional Schlieren methods can no longer be used as there is a progressive loss of contrast in the records that cannot be overcome by any normal modification to the apparatus or in the photographic processing.

In addition to limitations to the dimensions of mirrors and lenses used in conventional Schlieren techniques, the effects of diffraction may result in a change of illumination on the viewing screen, which differs appreciably in both extent and magnitude from that expected on the basis of geometrical optics. These effects may considerably affect the accuracy of the Schlieren technique when used to quantify density variations.

Even when high-speed cine cameras are used to quantify complicated dynamical processes (like internal waves in stratified fluid), the picture sharpness is usually less satisfactory in a direction along the film than across it[16].

Toepler–Schlieren photography can only offer the phase configurations, but our technique can determine the amplitude and phase of the signature using standard signal processing techniques. Moreover, the fact that none of the limitations associated with conventional Schlieren techniques arise when internal waves are monitored using the present method justifies that the technique reported here is more effective and sensitive.

Results and discussion

Typical time series plots of the density fluctuations, i.e. the raw data, along with a plot depicting the noise in

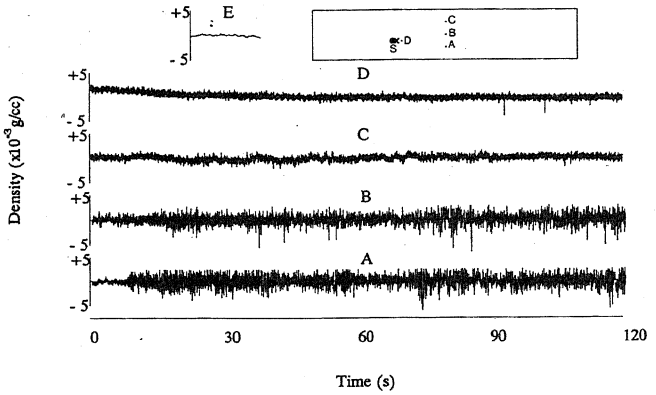

Figure 4. Time series of the observed density fluctuations caused by the turbulent wake and internal waves at different vertical locations A, B, C, D. Data run E depicts the ambient noise level at the location of A when the propeller was inoperative. Inset is a schematic diagram showing locations of runs A, B, C, D and the body S.

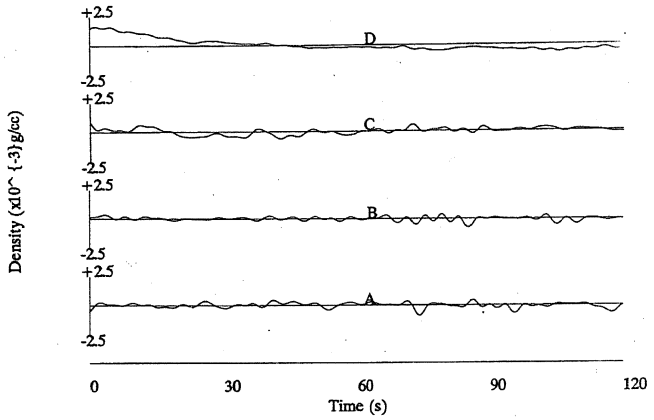

Figure 5. Time series of the low passed density fluctuations at different vertical locations. The data are the same as those shown in Figure 4.

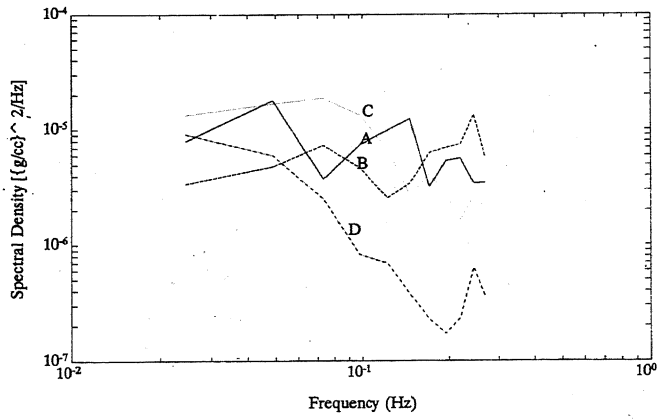

Figure 6. Spectral densities of the low passed density fluctuations recorded at different vertical locations A, B, C, D. The units on Y-axis are $[(g/cc)^2/Hz]$. Frequency resolution is 0.0244 Hz. Degrees of freedom ≅ 10.

measurements (i.e. when the signatures were observed while the water in the tank was undisturbed, the propeller being stationary) are shown in Figure 4. Two inferences become evident from Figure 4. One, the amplitudes of the fluctuations are small, indicating the minimal forcing applied on the propeller of the stationary body to avoid reflections and significant mixing; and two, the technique is very sensitive having minimal noise as can be seen in the uppermost plot of Figure 4. The maximum Brunt-Väisala frequency for our stratification was of the order of 0.2 Hz as reported earlier. Hence, the raw time series data were low passed using a Chebyshev filter with a cut-off frequency at 0.2 Hz to remove extraneous signatures, presumably associated with nonlinearities and turbulence, from analysis of internal wave dynamics. However, it may be noted that the detector does not yield any output corresponding to that part of the turbulence which does not induce any change in RIG in the medium. Figure 5 shows some typical time series plots of the low passed density fluctuations considered in the present study. Spectral density plots of the low passed raw data are shown in Figure 6. Spectral computations were performed using a Hanning window with 50% overlap. The spectral estimates have approximately 10 degrees of freedom with a frequency resolution of 0.0244 Hz. The spectral observations have been resolved into eight frequency bands. Significant spectral energy levels at different frequency bands can be observed in Figure 6.

A	–0.259	0.190	0.074	0.158	–0.071	0.067

The origin of the horizontal distances is the source of forcing. A – F denote vertical locations separated by 2.5 cm.

Tables 1 and 2 show the scalar wavenumbers, corresponding to two frequencies in the internal wave band, computed as $k_x = \Delta\phi_x/\Delta x$, and $k_z = \Delta\phi_z/\Delta z$, where k_x is the horizontal wavenumber in the X-direction and k_z is the vertical wavenumber in the Z-direction and $\Delta\phi_x$, $\Delta\phi_z$ are the autospectral phase differences in the respective X and Z directions. Although k_x and k_z computations do not correspond to the same location, they do suggest that those in the X-direction are of an order of magnitude less than those in the Z-direction. This is consistent with the laboratory set up of a vertically stratified water column in the wave tank, which inhibits propagation in the vertical. As a result, the spatially inhomogeneous turbulence undergoes a transition to two-dimensional motion under the action of stratification, and there would be a propensity for a stronger horizontal propagation, as suggested by the recent stratified shear flow experiments[17,18].

However, the basic observations which suggest that turbulence dominates in the near field of the source and

internal waves generated by the collapse of the turbulent wake dominate in the far field (see the raw time series plots in Figure 4 and low passed plots in Figure 5) are consistent with earlier studies[19,20]. Close to the centre of the disturbance, internal waves generated due to the displacement effects of the propeller propagate in a narrow region along the axis of the generating source[21]. This feature is reflected in the time series plots of run D.

The spectral observations in Figure 6 show that near the source (runs A & B), turbulence manifests (broad band spectra) and along the axis of the source (run D), internal wave signatures manifest as higher energy in the lower frequencies of the spectra, rapidly decaying towards higher frequencies. The spectral peaks associated with different frequencies at different locations are indicative of the multiple interactions between various components creating nonlinear energy transfers[22,23].

Conclusions

A novel optoelectronic technique to directly monitor internal waves in the laboratory was demonstrated. The technique is highly sensitive and is free from the conventional experimental constraints. It can be easily adapted for use in field experiments.

With the decreasing size of habitat and increasing fragmentation, it has become essential to develop species-specific habitat suitability maps. Such an approach for endangered species is a priority task for India's conservation programme. The mountain goat (goral) is an endangered species. The viable population of goral (*Nemorhaedus goral*) on Siwalik mountain is now confined to only Rajaji National Park, Uttar Pradesh. The goral habitat is restricted to specific land attributes, viz. landcover, slope, water availability and human habitation. Human settlements, biotic pressure (grazing and lopping) and erosional subsidence on hills have threatened goral habitat. The study is an attempt to model habitat suitability using spatial landscape patterns (interspersion and juxtaposition) and specific habitat requirements (restrictive factors). The approach has been tested in the part of Rajaji National Park for goral.

HABITAT is a place occupied by a specific population within a community of populations[1]. Habitat selection is an important part of an organism's life history patterns. The worldwide destruction of the natural environment is reducing the number of species and the amount of genetic variation within individual species. Major threats to biodiversity include habitat alterations, overharvesting, pollution, climate change, introduced species and human population increase. Of these, habitat alterations due to overuse, deforestation and consequent habitat loss, fragmentation and degradation are the primary factors[2]. There is a need to identify priority areas for conserving wildlife habitat. India's conservation effort is evolved around the UNESCO protected area concept by creating biosphere reserves, national parks, and sanctuaries. About 3.4% of India's geographical area is under protection for '*in situ*' biodiversity conservation. The approach takes into account endangered species and habitats. However, with mounting pressure on the protected areas and species, the approach is under review. It is now considered imperative to analyse baseline data on the physical set-up, vegetation and socioeconomic environment to ensure the effectiveness of the conservation effort.

Unfortunately, the study area (Rajaji National Park, Uttar Pradesh, India) has suffered from habitat loss, near fragmentation and degradation. The area around Rajaji National Park has had a twofold increase in human population from 1951. The increase in the human population has accentuated the biotic pressure on the forest[3].

The most characteristic Himalayan mammal of this park is the goral, a mountain goat. Johnsingh[3] has described the animal and its habitat requirements. The goral (*Nemorhaedus goral*) is a stocky goat antelope, 65–70 cm at the shoulder and 25–30 kg in weight. Both sexes have horns and a conspicuous white throat patch.

Goral habitat

Three species of goral inhabit the Himalaya, northeast part of India, Burma, China and Thailand[4]. The Himalayan goral (*Nemorhaedus goral*) is found from 200 msl in the Siwalik Hills to 4000 msl in the main Himalayan range[5]. The Siwalik forest landscapes of the Himalayas are exposed to various degradational processes due to their fragile geomorphology and heavy human dependency. Rajaji National Park is an attempt to protect the representative biogeographic unit (Gangetic plain). Goral habitat has been extensively studied and it is established that goral has a very specific habitat requirement[3,6–10]. The habitat size has been shrinking due to fast degradation caused by the lopping of trees, grazing and cutting of grass, and erosional subsidence of slopes. This has threatened the survival of goral.

The habitat parameters required for goral were summarized based on the field observations and literature:

– Goral is not seen near human habitation.

– Goral is a grazer. It selects vegetation with good grass cover.
– It avoids lesser slope angle categories and prefers areas with higher slope.
– Escape terrain is either a cliff, steep slope or '*nalah*'/gully followed by broken/rocky terrain. But cliffs are one of the most important escape terrains; forest cover seems to be the next highly used escape routes[8].
– Goral avoids areas with extensive shrub cover. This was related to forage availability as well as its anti-predatory strategy.

In spite of the species being endangered, no attempts have so far been made to analyse spatial habitat suitability and the available habitat size.

Habitat evaluation approach

The colonization pattern of the animals is related to the following parameters: cover, physical set-up and land use. The habitat suitability analysis based on these parameters is considered essential to protect the species. Since long time, ground methods have been used to evaluate the habitat using habitat suitability index based on ground observations[11,12]. However, these methods do not provide any spatial information. Aerospace remote sensing has been used effectively to characterize the habitat[13–15]. Subsequent attempts have also been made in India to evaluate wildlife habitats and related parameters using remote sensing data[16–18]. These studies, however are subjective and do not take into account spatial patterns and diversity of landscape. Researchers have used Geographic Information System (GIS) to handle multi-layered data and analyse spatial patterns statistically[19]. The model can be driven for different combinations of the controlling factors identified from a GIS database to predict suitability[20].

This study presents an approach to identify goral (*Nemorhaedus goral*) habitat based on analysis of spatial patterns of landscape. A remote-sensing-derived vegetation map, water sources, human settlement, road infrastructure and digital terrain model are the basic inputs for the study. The habitat suitability has been derived based on spatial patterns of landscape and the specific habitat requirements of goral.

Study area

The study area is located in Dhaulkhand range of the Rajaji National Park (77°55′35″E to 78°4′42″E longitude and 29°59′45″N to 30°8′48″N latitude) covering an area of 149.6 km^2 (Figure 1). The topography of the area varies with altitude, ranging from 320 m above msl in submontane area to above 800 m in the Siwalik ranges. The climate is subtropical. Rainy season commences from late June and continues up to the middle of September with the heaviest rainfall recorded in August (range 1200–1500 mm). The average annual rainfall is about 1270 mm. The temperature varies from 13.1°C (in January) to 38.9°C (in June). The vegetation mainly belongs to the northern tropical dry deciduous forest and sub-tropical forest[21]. Among fauna, herbivorous game animals of the deer family, cheetal (*Axis axis*), hog deer (*Axis pornicus*) are common. Large mammals like elephants are abundant.

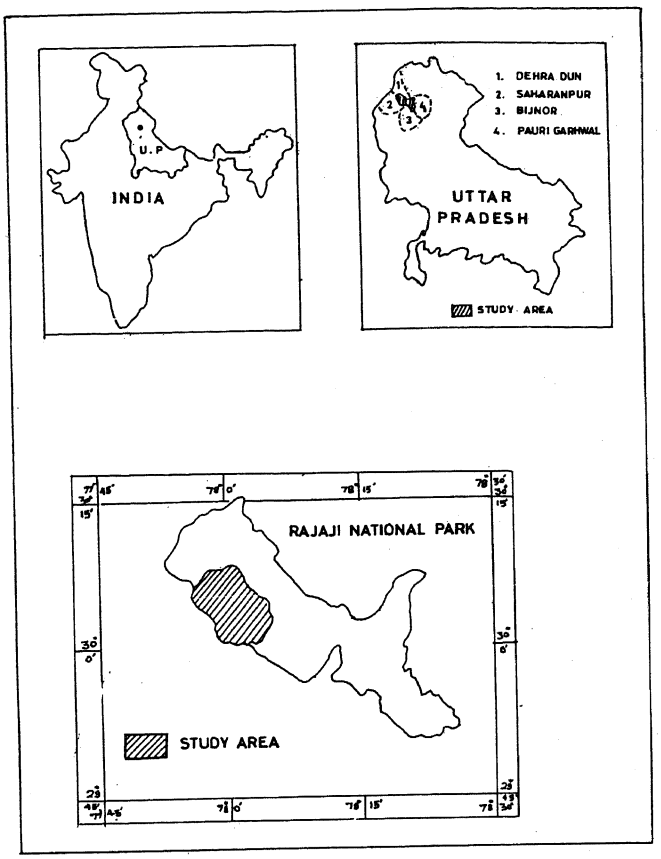

Figure 1. Location map of the study area.

Materials and methods

Input data

Indian Remote Sensing Satellite-1B Linear Imaging Self Scanning Sensors (IRS–1B LISS II) (with ground resolution of 36.25 m) false colour composite (FCC) of bands 4, 3 and 2 have been used to prepare the vegetation map on a 1:50,000 scale. The vegetation types and associated land use details interpreted are sal (*Shorea robusta*) (S), sal mix (SM), miscellaneous (M), miscellaneous with grass (MG), chir (*Pinus roxburghii*) (C), chir with grass (CG), scrub (Sc), riverine (r), plantation

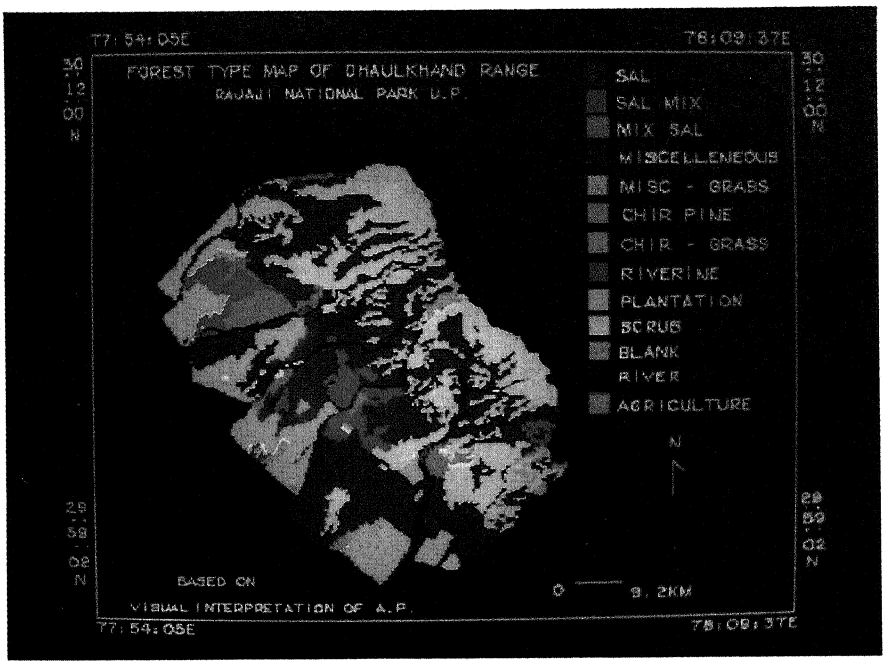

Figure 2. Forest type map of Dhaulkhand Forest Range, Rajaji National Park, UP.

Table 1. Locations where gorals were sighted either feeding/resting

	Habitat parameters			
Location	Slope (degrees)	Forest type	Water	Habitation
Dhaulkhand ridge near Sayyawala point	35–60	Misc. with grass, Misc.	Within 1 km	Nil
Dhaulkhand ridge about 200 m NW from point 1	35–60	Misc. with grass, Misc.	Within 1 km.	Nil
Ridge between Gularia and Tangsot towards Tangsot	>70	Misc. with grass	Within 100 m	Nil
Gulari ridge	>60	Misc.	Within 100 m	Nil
Ridge between Gulari and Tangsot point towards Dhaulkhand road	>50	Misc. with grass	Within 100 m	Nil

(Pt), agriculture (Ag), drainage and water bodies (Figure 2). The terrain features like contours and roads were obtained from Survery of India toposheets. The known habitat parameters for goral (from field and literature) were used along with the spatial information in GIS.

GIS approach

PAMAP GIS configured on PC-based platform has been used in the present study. The maps showing vegetation/land use, contours, water and human habitation were digitized. The contours were interpolated to calculate digital terrain model (DTM) and the slope map was derived. Finally, the spatial information along with restrictive factors (Table 1) were modelled using overlay and neighbourhood techniques. The study approach is presented in Figure 3.

Results

Spatial pattern analysis

The vegetation landscape is analysed to determine habitat interspersion and juxtaposition. The interspersion (Is) is a measure of the spatial intermixing of habitats/land use and is calculated in a nonspecies-specific

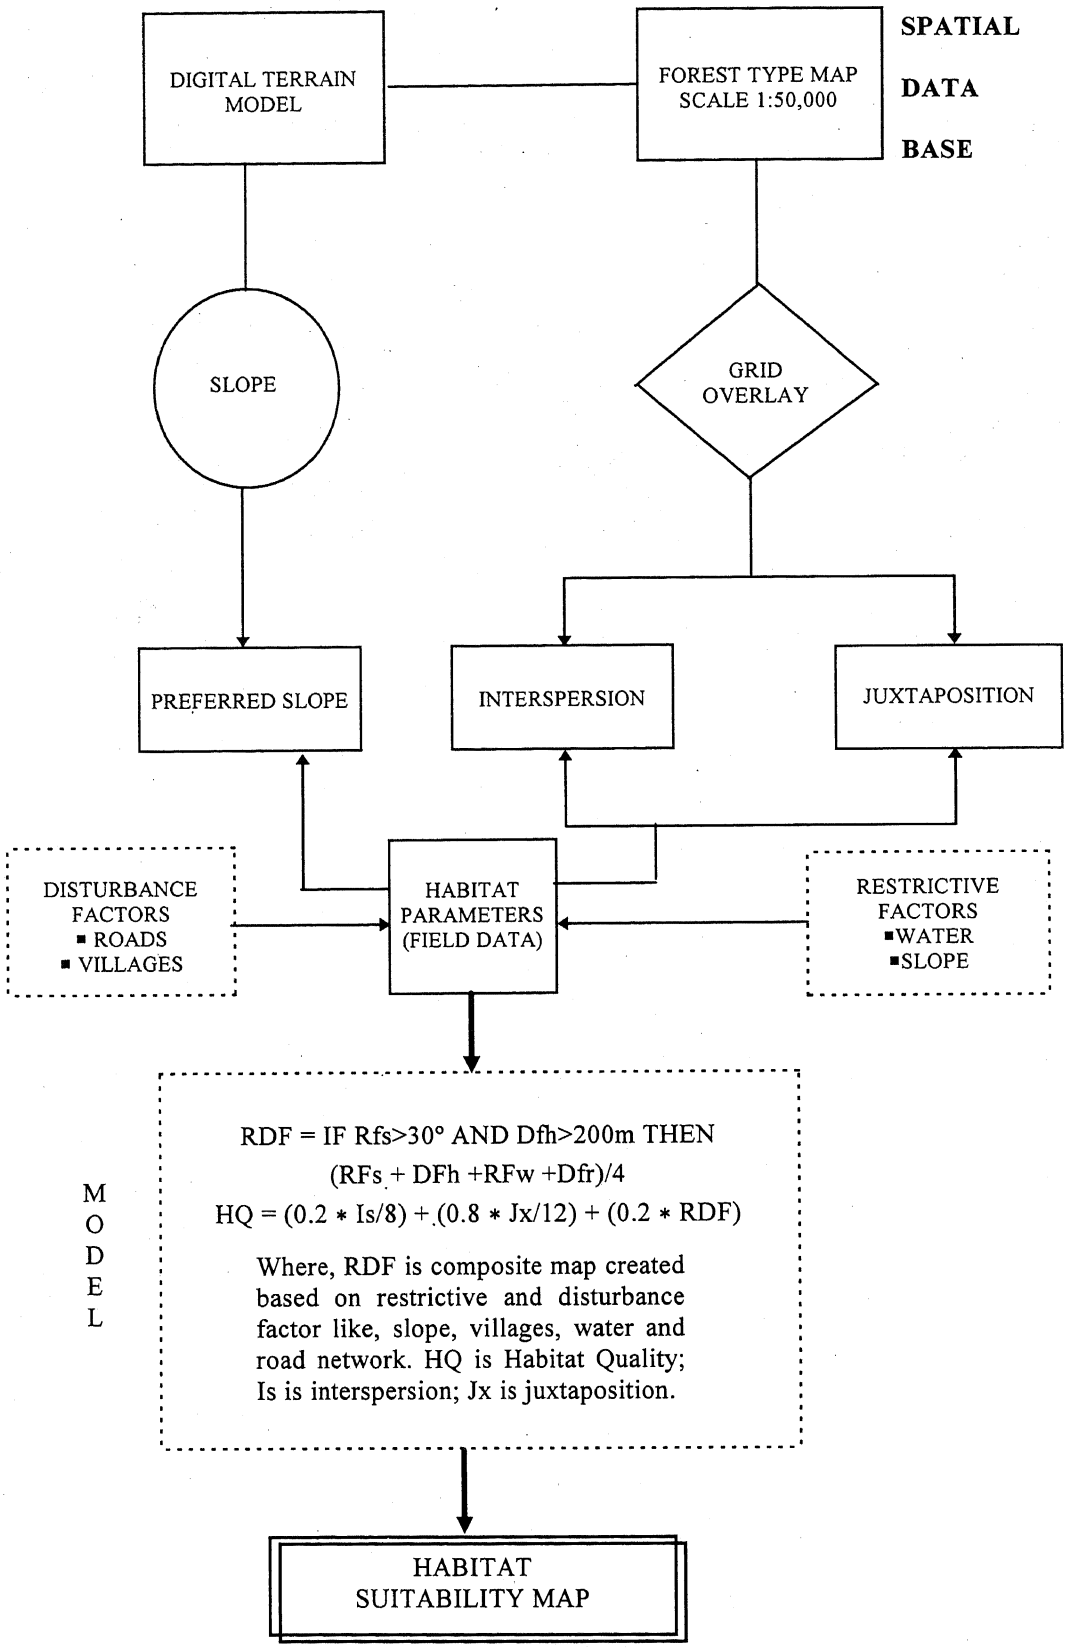

Figure 3. Approach for habitat suitability analysis.

manner[12,22]. The juxtaposition (Jx) is a measure of the proximity of habitat types and relative importance of adjacency[12,23]. Thus, Jx is a measure species-specific to goral. This was accomplished by defining a grid which was placed on a forest type map. Based on the field observation on the habitat size, grids of 20 s × 20 s were used for the present study. Grid sizes can be changed as per the required level of details. Gridwise interspersion and juxtaposition were calculated using a software developed in database management system (dBase III+) interfaced with PAMAP GIS. The weightage factors were assigned to different edges based on the order of preference by goral.

Measure of interspersion

A window of size 3 × 3 grids panned over vegetation map and an interspersion value was assigned to the central grid to prepare the interspersion map. Interspersion of central cells is calculated as the number of surrounding grid cells that differ from the central cell. The interspersion of a given window is 6. The maximum limit of interspersion is 8.

MG	MG	M
S	MG	M
S	Sc	S

Measure of juxtaposition

The juxtaposition of the central grid cell is calculated by comparing the class of the central cell with an adjacent cell as per the weighted preference of the species on use of the habitat. The length of the edge (diagonal or horizontal/vertical) is also provided as a weightage. The habitat preference and weightage criteria are given as follows.

Goral habitat preference of vegetation cover in descending order is:
Miscellaneous forest with grasses on slopes (MG) – Chir-Pine with grasses on slopes (CG) – Miscellaneous (M) – Chir-Pine (C) – Miscellaneous sal (MS) – Sal miscellaneous (SM) – Scrub (Sc) – Blanks (B) – Riverine (R) – Sal (S) – Plantation (Pt) – Agriculture (Ag). The weightages assigned to different edges are given in Table 2. Calculation

Table 2. Weightage assigned to different edges of vegetation types

Vegetation type factor	Association	Weightage
Miscellaneous forest with grasses on slopes	Any cover	0.9
Chir-pine with grasses on slopes	Any cover	0.9
Miscellaneous forest	Chir-pine with grasses, miscellaneous, scrub and blanks	0.9
Miscellaneous forest	Any other cover	0.6
Miscellaneous sal	Any cover	0.6
All other combinations		0.2

Table 3. Measure of juxtaposition

Edge combination	Weightage factor (specific to goral)	Quantity	Juxtaposition (Jx)
M/Sc	0.6	3	1.8
MG/Sc	0.9	3	2.7
C/Sc	0.2	2	0.4
R/Sc	0.2	1	0.2
Sc/Pt	0.2	2	0.4
Sc/Ag	0.2	1	0.2

Note: Diagonal count as 1, while vertical or horizontal count as 2.

of juxtaposition for the central grid of the given window is given in Table 3 and is equal to 5.7.

M	M	MG
S	Sc	C
Ag	Pt	R

The juxtaposition in the study area ranges from 2.4 to 10.8. The maximum limit of juxtaposition is 12.

Restrictive (RF) and disturbance (DF) factors

The factors that are essential for wildlife species are called restrictive factors. The presence of this factor is indicated by value one and has no impact on habitat suitability index; otherwise the factor is zero and, consequently, habitat suitability index becomes zero. Intermediate values can also be assigned based on field conditions and habitat requirements of wildlife. Based on habitat use by goral, four restrictive factors were determined.

Water availability (RFw). The availability of water within 1 km is the most important requirement of goral habitat. This was accomplished by generating the map showing a distance buffer around water sources and assigning ratings (0 to 1) based on the proximity.

Slope (RFs). Ratings (0 to 1) were given for slope classes. The rating values are 0, 0.8 and 1 for slope classes <30°, 30°–50° and >50°/cliffs, respectively.

Remoteness from human habitation (DFh). The human habitation is considered a disturbance factor. The presence of villages may alter the suitability of the grid. This was accomplished by generating the map showing a distance buffer around village locations and assigning ratings (0 to 1) based on proximity.

Remoteness from roads (DFr). The roads, although do not have significant impact on habitat, are considered a potential habitat disturbance factor. This was also accomplished by generating the map showing a distance buffer around roads and assigning ratings (0 to 1) based on proximity.

The cost surface developed using these four factors is called restrictive and disturbance factor map (***RDF***). This map was generated using the logic given below:

CREAT **RDF** IF RFs >30° and IF DFh > 200 m THEN (RFs + DFh + RFw + DFr)/4

Figure 4 displays the quality of habitat based on slope and proximity to water, road and human habitation. This map was used along with interspersion and juxtaposition maps to determine the final habitat suitability map.

Habitat suitability index

The habitat suitability is a function of interspersion, juxtaposition and restrictive factors. It is determined based on different weightages assigned to each parameter. The equation used for calculating the habitat suitability index is given below.

habitat index = (0.2*Is/8) + (0.6*Jx/12) + (0.2*RDF).

Thus, each cell was assigned a habitat suitability index ranging from 0 to 1. Histogram equalization was followed to cluster showing different habitat quality zones, viz. highly suitable, moderately suitable, less suitable and not suitable (Figure 5).

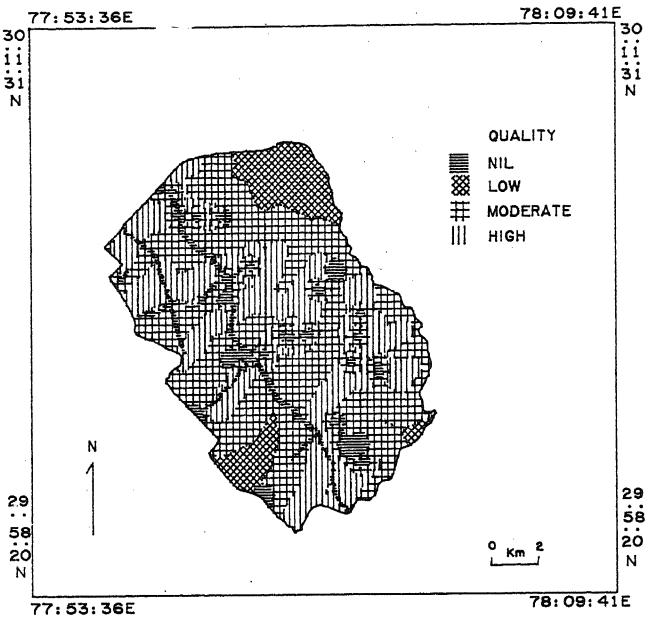

Figure 4. Cost surface created using restrictive and disturbance factors.

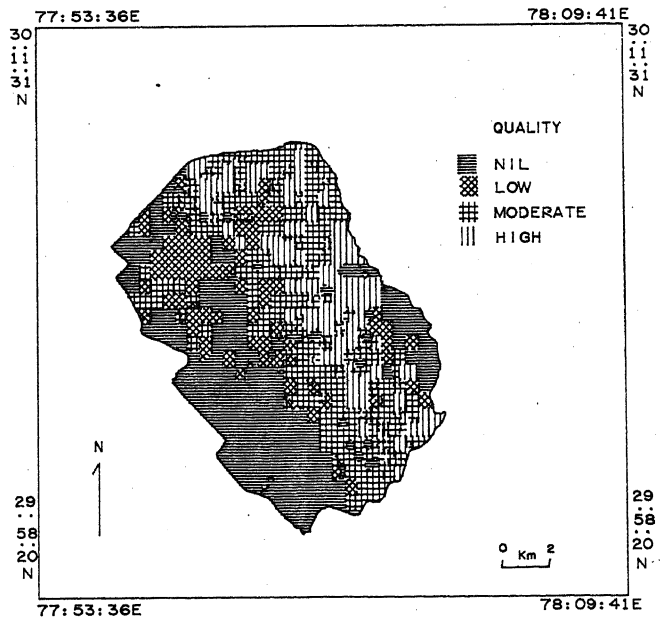

Figure 5. Habitat suitability map for goral in Dhaulkhand range, Rajaji National Park, UP.

Model comparison with field data

The suitable locations for goral noted down during the field work were superimposed on the habitat suitability map. Out of 10 locations, 5 are in most suitable areas, 3 in moderately suitable areas, 2 in less suitable areas and none in unsuitable areas.

The area under each category in percentage is as follows:

Habitat quality	Percentage area
Most suitable	35.22
Moderately suitable	15.15
Low suitable	29.47
Not suitable	20.16.

Discussion

With decreasing habitat and increasing fragmentation, it has become essential to develop species-specific habitat suitability maps. Such an approach for endangered species is a priority task for India's conservation programme. The mountain goat is an endangered species. The viable population of goral on Siwalik mountain is now confined only to Rajaji National Park. In the recent years, increasing human impact within the national park has threatened the very existence of goral in Siwalik. The present study is an attempt to develop an approach for habitat suitability mapping using spatial landscape patterns and specific habitat requirements. The model uses goral habitat parameters reported by Green[8] and Johnsingh[3].

The habitat studies indicate that homogeneity/heterogeneity of landscape, vegetation types, their association and edges characteristics are important parameters. Abundance of these species may be considered a consequence of edges where types of food and cover come together. The edge effect may be defined as the tendency for an increase in variety and density of an organism at a community junction. The present study tries to model it through measurement of interspersion and juxtaposition. The weightages of these two are based on species habitat preference. The conceptual framework on the use of these parameters has been discussed by Mead *et al.*[22] and Lyon[23]. Since the animal is shy to human presence, human habitation and road

proximity are also used in the model as parameters. The topographical habitat features and the availability of water have also been used as restrictive factors in the present model. The present study attempts to implement habitat suitability approach for the mountain goat.

Conclusion

India has large biodiversity. However, recent population growth trends have put tremendous pressure on the habitats. The situation calls for urgent need to develop comprehensive database of the protected areas, which are temples of *in situ* conservational efforts. It is necessary to evaluate the available habitat size, quality and socioeconomic constraints. The present approach can provide information about the suitability of endangered species having very specific habitat requirements. There is need to implement such an approach for the species which are dwindling and becoming endangered due to shrinking habitat size.

Carbon and oxygen isotopic records of planktonic and benthic foraminifera from a new deep-sea core of the northeast Indian Ocean

S. Masood Ahmad

National Geophysical Research Institute, Hyderabad 500 007, India

Stable carbon and oxygen isotopic records of the planktonic foraminifera (*Globigerinoides ruber*), covering the past ~100,000 years, have been obtained from a new deep-sea core of the Bay of Bengal. High glacial-to-interglacial $\delta^{18}O$ amplitude (2.0‰) in the surface waters of this region provide evidence for the increased salinity (by ~2‰) in the glacial surface waters of this region[1,2]. In contrast, the surface water $\delta^{13}C_{TIC}$ did not change significantly during the glacial-to-interglacial transition.

Examination of the isotopic record of benthic foraminifera (*Cibicidoides* and *Uvigerina*) shows higher (1.7‰) glacial-to-interglacial $\delta^{18}O$ amplitude. This is attributed to the decrease in deep-water temperature arising from changes in source characteristics during the LGM. The glacial-to-interglacial shift in $\delta^{13}C_{TIC}$ (~0.3‰) in the deep Bay of Bengal is close to the global

$\delta^{13}C$ change, in conflict with the previous reports that suggested marked enrichment of nutrients in deep waters of the northeast Indian Ocean.

STABLE carbon and oxygen isotopic analyses in the planktonic and benthic foraminifera from the deep sea cores of the northern Indian Ocean have shown significant changes in the chemical characteristics of the surface and deep-water masses since the last glacial maximum (LGM)[1–7]. Previously published oxygen isotopic records of the planktonic foraminifera from the Northeast Indian Ocean (NEIO) are suggestive of much higher salinity as compared to today in the glacial surface waters of this region due to a reduction in riverine input[1,7]. A large influx of pollen from the Irano–Turanian Steppe and high percentage of quartz observed in the glacial sections of sediment cores also support prevalence of high aridity in the region and a weakening of the southwest monsoon during the last glaciation[8,9].

Heavy precipitation during the southwest monsoon over the Indian subcontinent is collected by the major rivers (Ganges, Brahmaputra, Salween and Irrawady) which drain into the northeast Indian Ocean. As a result, a strong north–south salinity gradient forms in the Bay of Bengal, which is reflected in the $\delta^{18}O$ distribution pattern of the Holocene planktonic foraminifera[1]. The deep Bay of Bengal is filled with water originating in the circumpolar region and transported northward by the two western boundary currents[10]. The water found at the site of the core SK-72 (water depth 3246 m) has an important component from the relatively warm North Atlantic Deep Water (NADW).

The hydrographic structure of the deep and intermediate water in the northern Indian Ocean experienced considerable changes during the last glacial maximum[3,5]. The $^{13}C/^{12}C$ and $^{18}O/^{16}O$ ratios in shells of benthic foraminifera showed that, during the last glaciation, water column in the northern Indian Ocean was highly stratified, with a well-marked boundary between the intermediate- and deep-water masses[3], in contrast to the present conditions, when the $\delta^{13}C$ gradient is very small (0.1‰)[11]. To explain this glacial stratification, a mechanism involving the transfer of nutrients from the intermediate to deep waters was suggested[12,13]. But more recent data from intermediate-depth cores of the NEIO showed that the glacial $\delta^{13}C$ gradient was not as high as reported earlier[5,6]. The temperature of glacial intermediate- and deep-water masses in NEIO was also lower by at least 1–1.5°C compared to the present bottom water of this region[3,5,14].

The distribution of carbonates in deep-sea sediments is controlled by the depth of the lysocline, where the rate of calcite dissolution increases sharply and by the carbonate compensation depth (CCD), below which calcium carbonate does not occur. The biological productivity, water depth, chemistry and dilution by non-carbonate components are the main factors influencing

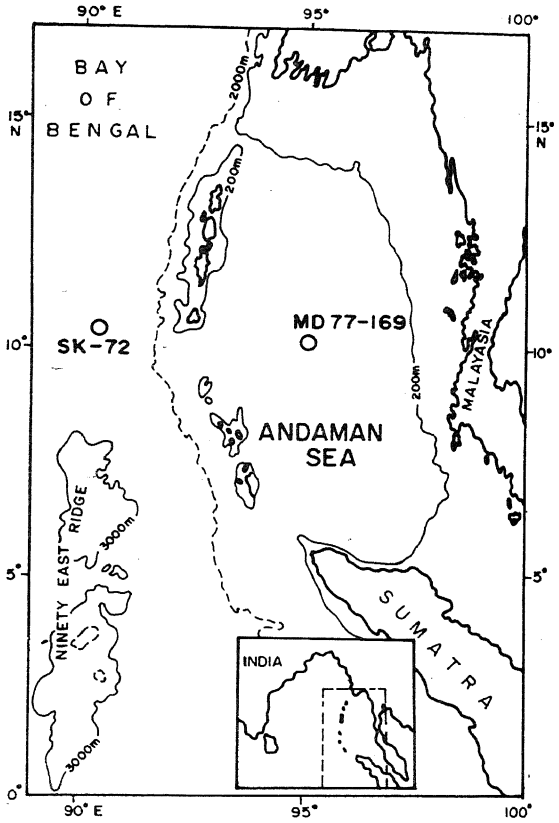

Figure 1. Location map of the cores SK-72 and MD 77-169.

carbonate content of the sediments[15]. In addition, the deep-water circulation pattern also plays an important role in determining carbonate distribution[15,16]. As a result of these changes, the depth of the lysocline varies considerably, both locally as well as globally.

The box core SK-72 was retrieved from the Bay of Bengal (10°43′N and 90°27′E) during February/March 1992 at a water depth of 3246 m (Figure 1). The core was subsampled for this study at 10–20 cm intervals except within the Holocene section, where samples were taken at 5 m intervals. The sediment samples were soaked in distilled water overnight and subsequently washed through a 150 μm sieve and dried at 60°C. About 15–20 foraminiferal tests in the size range of 250–315 μm were then picked under a microscope for isotopic measurements.

The separated specimens were ultrasonically cleaned to remove adhering particles and roasted under vacuum at 400°C for 1 h. The CO_2 was extracted by the reaction of foraminiferal calcite with 100% phosphoric acid at 50°C on an on-line system and the isotopic ratios were measured using a VG Micromass 903 mass spectrometer. The precision based on the replicate measurements of the internal laboratory standard MMB for both carbon and oxygen was better than ±0.1‰. The results are expressed relative to PDB standard (Table 1). *Cibicidoides* oxygen isotopic values were converted into *Uvigerina* scale by adding 0.64‰ (ref. 17), while carbon isotopes

Table 2. Age against depth data for core SK-72. Ages are estimated from the time scale derived for the normalized SPECMAP curve by Imbrie *et al.*[19]

Event	Sub-bottom depth (m)	Age 10^3 yr
1.1	0.2	6
2.0	0.4	12
2.2	0.8	18
3.1	1.2	24
3.3	2.0	53
4.0	2.39	59
4.2	3.0	65
5.1	3.4	80
5.2	3.6	87
5.3	3.8	94

of *Uvigerina* were brought to the *Cibicidoides* scale by adding 0.83‰ (ref. 18). Carbonate contents were determined by weight loss after leaching the samples with dilute (50%) hydrochloric acid. The reproducibility of the carbonate abundance estimate is better than ±2% based on six replicate measurements.

Age assignments and correlation of cores are based on the planktonic oxygen isotopic stratigraphy by using graphic correlation of the SPECMAP $\delta^{18}O$ record (Table 2)[19]. The average sedimentation rate in SK-72 is about 4.1 cm/ka. The planktonic record of SK-72 correlates well with another core (MD 77-169) of the northeast Indian Ocean[7].

The results of the oxygen isotopic analyses of the surface-dwelling planktonic foraminifera *Globigerinoides ruber* in SK-72 are plotted against time in Figure 2. The observed glacial-to-interglacial $\delta^{18}O$ amplitude exceeds the ice volume effect of ~1.2‰ (ref. 20) by 0.8‰. This could arise from either a cooling of surface waters by about 3°C (ref. 21) or from an increase in salinity by ~2‰ (ref. 22), or from a combination of both the factors. However, earlier studies have shown that the glacial surface temperature in the Bay of Bengal did not differ by more than 1°C from the present SST[1,22]. Therefore, the glacial enrichment in $\delta^{18}O$ could be attributed mainly to the increased salinity. Comparison of the $\delta^{18}O$ records between SK-72 and the Andaman Sea core MD77-169 indicates generally lower ^{18}O in the Andaman Sea, because core MD77-169 comes from a region which is greatly influenced by runoff from the rivers Irrawady and Salween.

The LGM to core top change in $\delta^{18}O$ for the benthic foraminifera (~1.7‰; Figure 3) is also considerably higher than the ice volume effect[20]. Since there is no evidence for any local deep water formation in NEIO during the last glaciation, the higher glacial–Holocene shift in benthic $\delta^{18}O$ in this region should be due to a decrease in deep-water temperature as a result of the changes in source waters[14,23]. It is quite likely that the glacial deep water in the Bay of Bengal had a greater contribution from the Antarctic Bottom Water (AABW) at the expense of warmer NADW as production of the latter was greatly reduced during the glacial times. The additional $\delta^{18}O$ enrichment (~0.5‰) in SK-72 implies a cooling by about 2°C; this is somewhat higher than the previous estimate (1.5°C)[3]. However, it must be noted that these computations assume no local salinity change in excess of that included in the global ice volume effect. If there was a local increase in salinity as well (which is likely given the dramatic increase in surface salinity during the LGM and the consequent downward diffusion of salt through the water column), the magnitude of cooling would be smaller.

The present geographic distribution of $\delta^{13}C$ in the deep sea is related to the oxygen and nutrient contents

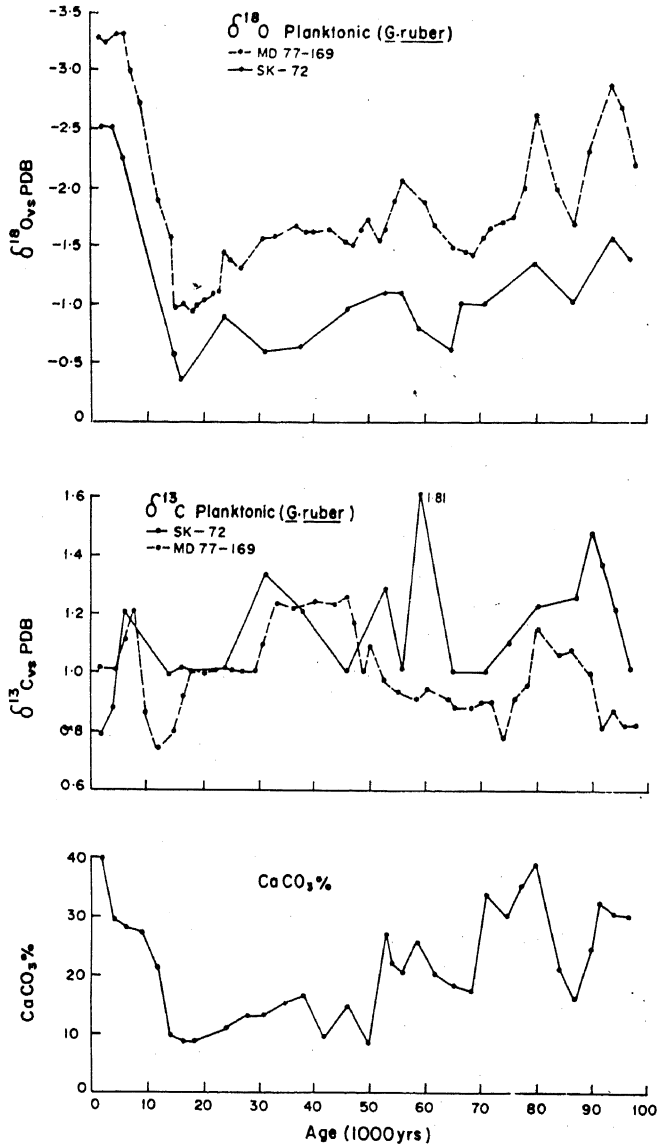

Figure 2. Carbon and oxygen isotopes in planktonic foraminifera (*Globigerinoides ruber*) and $CaCO_3$ percent in the cores SK-72 and MD 77-169 plotted against age.

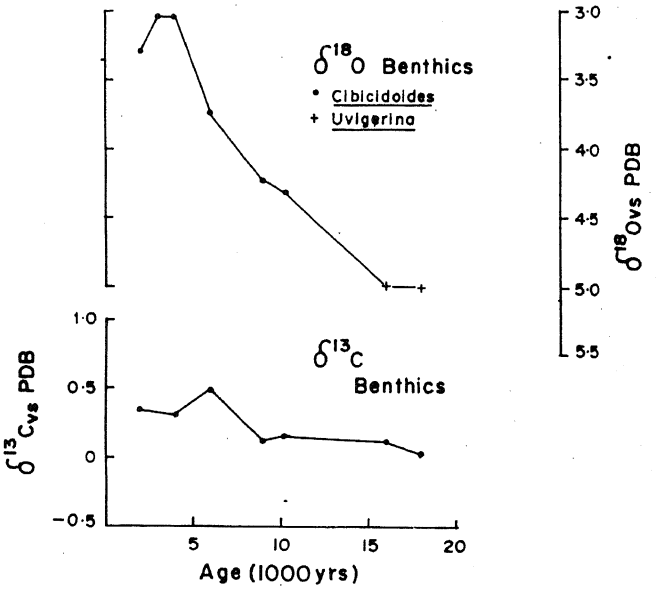

Figure 3. Stable isotopic record of the benthic foraminiferal genus *Cibicidoides* and *Uvigerina*. Oxygen isotopes of *Cibicidoides* corrected by adding 0.64‰ and carbon isotopes of *Uvigerina* corrected by adding 0.83‰.

and circulation pattern of the water masses[11]. However, during the last glaciation the deep-water circulation probably experienced considerable changes because of the decreased production of NADW[24,25]. Carbon isotopic data on benthic foraminifera belonging to the genera *Cibicidoides* and *Uvigerina* have shown that during the LGM deep-ocean $\delta^{13}C$ was lower by 0.32–0.46‰ compared to the late Holocene[4,18]. In SK-72 the maximum $\delta^{13}C$ difference (0.45‰) was observed between 20 and 100 cm levels. However, the mean glacial–interglacial $\delta^{13}C$ shift is only ~0.3‰ (Figure 3), which is very close to the global deep-water $\delta^{13}C$ shift. Recent studies from the intermediate-depth water cores from the North Indian Ocean have clearly demonstrated that the glacial mid-depth water masses in NEIO are also similarly depleted in ^{13}C by 0.3–0.4‰, compared to the Holocene[5,6]. Hence, the $\delta^{13}C$ gradient between the intermediate and deep waters was very similar to that observed today. It can, therefore, be concluded that the glacial NEIO did not experience a dramatic change in the vertical chemical structure (acute oxygen depletion and nutrient enrichment in the deep waters) as reported previously[3].

The carbonate content of SK-72 varies from ~8% to ~40% by weight (Figure 2). The carbonate content is high (39.4%) in the top portion of the core (0–5 cm), decreases rapidly to 8.5% at 100–105 cm and remains low down to 200 cm depth. Thereafter, the variation was relatively small. High carbonate contents correspond to interglacials (oxygen isotope stages 1 and 5), whereas low values are seen during the glacial stages 2 and 4. The carbonate content during isotopic stage 3 is also low. This $CaCO_3$ abundance pattern is consistent with the carbonate data of other cores in the North Indian Ocean[26,27]. The low $CaCO_3$ abundance during the glacial times could be attributed to the decrease in lysocline as well as dilution by terrigenous matter. As stated earlier, the glacial deep waters probably received a greater contribution of cooler AABW. The decrease in sea water temperature favours carbonate dissolution and this would have contributed to the observed decrease in sedimentary $CaCO_3$ content during glacial times.

Resistance to *Bacillus sphaericus* in *Culex quinquefasciatus* Say 1823

T. Adak, P. K. Mittal, K. Raghavendra, Sarala K. Subbarao, M. A. Ansari and V. P. Sharma

Malaria Research Centre, Indian Council of Medical Research, 22, Sham Nath Marg, Delhi 110 054, India

Biological control of *Culex quinquefasciatus* using *Bacillus sphaericus* was considered a practical solution because of its specific and prolonged killing action against mosquito larvae. To study the feasibility of *B. sphaericus* ('Spherix') in mosquito control, multicentric trials were undertaken. Initially, *B. sphaericus* was very effective but within a year, after 20–25 rounds of application, field populations of *Cx. quinquefasciatus* developed resistance up to 150-fold. Genetic studies revealed that resistance was recessive, autosomal and controlled by more than one gene. This is the first report on nature and mode of inheritance of resistance against *B. sphaericus* in mosquitoes.

CULEX quinquefasciatus Say, 1823, is the major vector in the transmission of lymphatic filariasis caused by the nematode *Wuchereria bancrofti* in the tropics. To control *Cx. quinquefasciatus*, *Bacillus sphaericus* is emerging as a promising larvicide[1,2]. Extensive multicentric field trials carried out by Malaria Research Centre in India showed that the spraying of 'Spherix' (a commercial preparation of *B. sphaericus* Russian strain B-101, Serotype H5a 5b;) at the rate of 1 g/m^2 provides control of *Cx. quinquefasciatus* breeding for 2–4 weeks[3,4]. After 20–25 rounds of continuous field application of *B. sphaericus* within a year, reduction in its efficacy against *Cx. quinquefasciatus* was noticed. In this communication we report the development of resistance against *B. sphaericus* in field populations of *Cx. quinquefasciatus* and its mode of inheritance in this species.

Adult mosquitoes from *B. sphaericus* sprayed and unsprayed areas of Farrukhabad and Ghaziabad (Uttar Pradesh), Madras (Tamil Nadu) and Panaji (Goa) were collected and transported to MRC laboratories in Delhi for colonization[5] and further studies. In addition to these field populations, two laboratory strains maintained since 1988, one each from Delhi state and Sonepat (Haryana) were also used in bioassay and genetic crosses. Bioassays were performed following the method of WHO[1] with necessary modifications[6]. One per cent stock suspension of Spherix in dechlorinated water was prepared fresh and was used immediately for the bioassays. Twenty-five late III/early IV instar larvae were placed in 250 ml of water containing the required dose of *B. sphaericus* for 24 h and scored for mortality. All the tests were carried out in two replicates at 27± 1°C. Dose–mortality responses of treated lines were analysed using probit regression method of Finney[7].

Dose–mortality regression of the field populations and two laboratory strains are given in Figure 1 and Table 1.

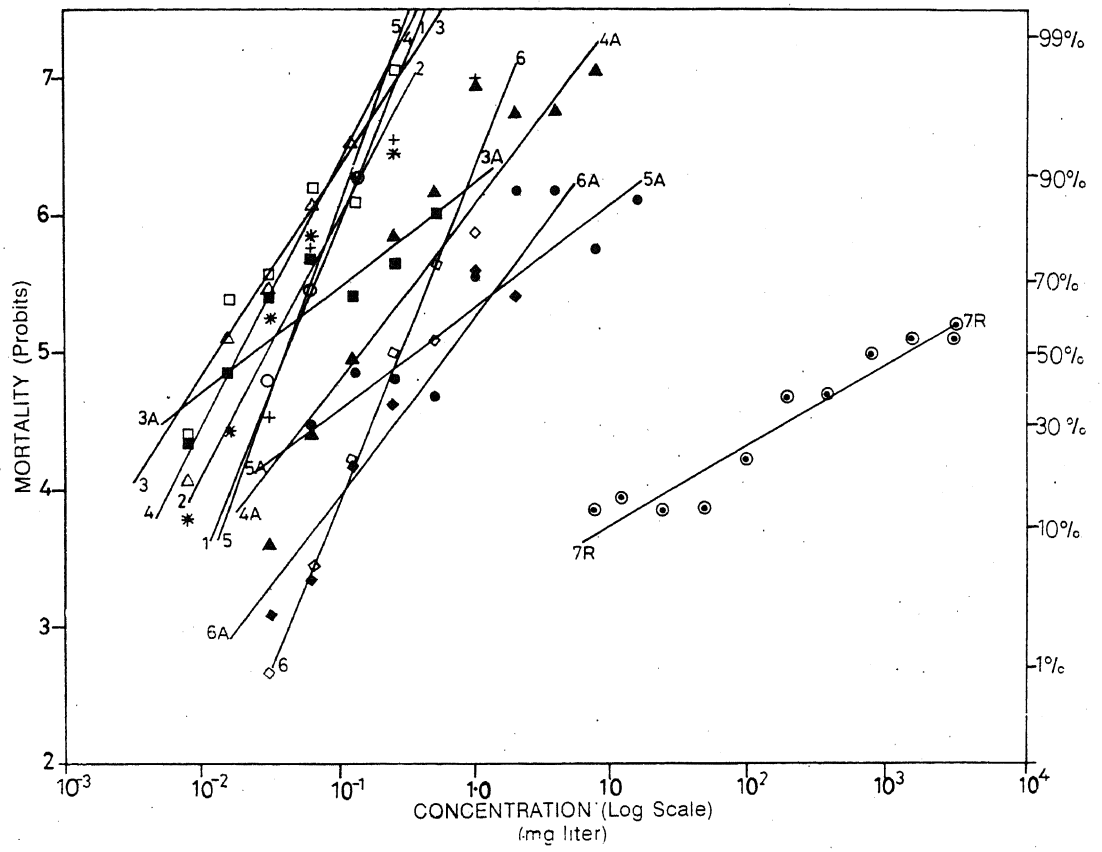

Figure 1. Dosage–mortality responses of susceptible laboratory strains from Delhi (1) and Sonepat (2) unsprayed (3–6) and sprayed (3A–6A) field populations: Farrukhabad (3,3A), Ghaziabad (4,4A), Madras (5,5A), Panaji (6,6A), and of homozygous *B. sphaericus*-resistant strain isolated from *B. sphaericus*-sprayed area of Ghaziabad (7R). Each point represents observed mortality after 24 h of treatment. At each dose 2–4 replicates (25 larvae/replicate) were used.

The LC_{50} and LC_{90} values in mg/l for Delhi and Sonepat strains were 0.04 and 0.032, and 0.134 and 0.137 respectively. These values are considered as those of susceptible populations, since these lines were established from areas where *B. sphaericus* was never sprayed. From the dose–mortality response, a dose of 2 mg/l, which was approximately double the value of $LC_{99.9}$ of susceptible strains, was calculated and subsequently used as diagnostic dose in the present studies.

The LC_{50} and LC_{90} values of the unsprayed field populations were similar to the two susceptible strains except those of Panaji, which were higher (Table 1). The higher LC_{50} and LC_{90} values in Panaji unsprayed areas could be due to the possible vigour tolerance as indicated by nonsignificant chi-square values tested for heterogeneity of response and also by the slope values which were similar to other unsprayed areas (Table 1, Figure 1). However, the LC_{50} and LC_{90} values of populations from unsprayed areas were significantly different from those of the populations from the sprayed areas. This was supported by the nonoverlapping 95% fiducial limits of LC_{50} and LC_{90} values[8] as given in Table 1. Of the four *Cx. quinquefasciatus* populations collected from *B. sphaericus* sprayed areas, chi-square values of the dose–mortality responses of Madras and Ghaziabad populations were significant ($P < 0.05$), indicating the heterogeneous nature of these populations (Table 1).

Data on LC_{50}, LC_{90}, slope values and resistance ratios as given in Table 1 clearly indicate the selection of resistance to *B. sphaericus* in field population of *Cx. quinquefasciatus*. A homozygous *B. sphaericus*-resistant strain of *Cx. quinquefasciatus* was isolated from a population collected from the sprayed areas of Ghaziabad. This strain is being maintained in the laboratory without further selection pressure. The LC_{50}, LC_{90} and slope values of the selected resistant strain in the F_6 generation were 1663 mg/l, >3200 mg/l and 0.5794, respectively (Table 1). The LC_{50} value of this strain was ~52000-fold higher than the value of the susceptible Sonepat strain. The resistant strain continued to remain resistant in subsequent generations, indicating the selection of a pure homozygous-resistant *Cx. quinquefasciatus* line. This homozygous-resistant line was subsequently used in genetic crosses.

To establish the genetic basis of resistance, the homozygous-resistant strain was reciprocally crossed with susceptible Sonepat strain. The LC_{50} (0.031 and 0.032 mg/l), LC_{90} (0.12 and 0.14 mg/l) and slope (2.26

and 2) of F_1 progeny from the reciprocal crosses were almost similar to those of the susceptible strain and all the progeny died within 24 h at the diagnostic dose (2 mg/l), indicating the recessive nature of *B. sphaericus* resistance.

In backcrosses with susceptible strain, mortalities ranged between 55.68 and 74.4%, which are well below the expected 100% at the diagnostic dose; however, mortalities reached 90–97% when scored after 48 h (after 24 h of treatment, larvae were kept in normal water). Data from crosses of F_1 progeny with resistant strain and F_1 inbreeding are given in Table 2. In backcrosses with resistant strain (crosses 1, 2, 4 and 5), mortalities were significantly below the expected 50%, and in both the F_1 inbreeding (crosses 3 and 6), dead and alive larvae deviated significantly from the expected 3:1 ratio. In all the crosses delayed effect of the larvicide was noticed. It is not clear why there was delayed mortality in all crosses, when no delayed effect of *B. sphaericus* was observed in the homozygous-resistant line and 100% mortality was observed among F_1 and susceptible progeny within 24 h of treatment. Data from the above crosses do not fit with the hypothesis that resistance to *B. sphaericus* in *Cx. quinquefasciatus* is monofactorial.

Table 2. Results from backcrosses and F_1 inbred crosses of *Cx. quinquefasciatus* strains resistant and susceptible to *B. sphaericus*

R: Resistant strain isolated from Ghaziabad.
S: Susceptible strain from Sonepat.
†Based on the hypothesis that resistance is monofactorial, expected number of larvae that would die at the diagnostic dose of 2 mg/l for 24 h.
*Significant at $P < 0.001$; ♀ = female ♂ = male.

In both F_1 inbreeding and backcrosses, among the larvae that survived, males and females were in 1:1 ratio, which indicated the linkage of the resistant gene to autosomes. In this context it may be mentioned that in *Cx. quinquefasciatus*, sex karyotype of males and females is the same, and the sex is determined by a pair of alleles, *m* and *M*. Females are homozygous for *m* (*m/m*) and males heterozygous (*m/M*). Though the F_1 progeny from the reciprocal crosses exhibited similar responses, to rule out sex linkage, surviving larvae from backcrosses and F_1 inbreeding were examined for sex by dissecting the reproductive organs. If the gene is sex-linked in F_1 inbreeding and in backcrosses, where F_1 males are heterozygous for the resistant gene, depending upon whether the resistant gene is introduced into the crosses along with *M* or *m* gene, the sex of the surviving progeny would respectively be either male or female. However, the recombinants would include the other sex. As in all the crosses males and females are in 1:1 ratio, linkage of resistant gene to sex chromosomes is ruled out.

The study has thus established that the resistance to *B. sphaericus* in *Cx. quinquefasciatus* is recessive, linked to autosome/s and is controlled by more than one gene. No maternal effect was observed in the expression of resistance. Further, the homozygous resistant strain was found fully susceptible to *B. thuringiensis israelensis*, the other commonly used biolarvicide, the LC_{50} and LC_{90} values being similar to those of the susceptible strain.

It is well established that a rare dominant gene is selected more rapidly than a recessive gene[9]. Since the gene for resistance in *B. sphaericus* is recessive, theoretically it should have taken a long time to develop resistance in the field populations. However, resistance appeared shortly after a year of spraying (20–25 rounds) in all sprayed areas. The probable reason for this could be that during larviciding, large population of immatures are continuously exposed, increasing the selection pressure[10].

Contrary to the presumption that insects are unlikely to become resistant to microbial pesticides[11], resistance in lepidopterans to *B. thuringiensis*[12] and now resistance in the mosquito *Cx. quinquefasciatus* to *B. sphaericus* has developed.

Lead impairs hepatic type I-5′-monodeiodinase activity and thyroid function in cockerels

S. S. Chaurasia, P. Gupta, A. Kar and P. K. Maiti

School of Life Sciences, Devi Ahilya University, Vigyan Bhawan, Khandwa Road, Indore 452 001, India

Chronic exposure of cockerels to 1.5 mg/bird/day of lead nitrate for a period of 30 days impaired thyroid function. Lead decreased serum triiodothyronine (T_3) concentrations, inhibited hepatic type I-5′-monodeiodinase enzyme activity and marginally increased serum thyroxine (T_4) concentrations. Our findings demonstrate the lead-induced inhibition of hepatic type I-5′-monodeiodinase enzyme activity in avian system, leading to decreased production of T_3, the most potent metabolic hormone.

TYPE I-5′-monodeiodinase (5′-D) is a microsomal membrane-bound enzyme[1]. The most potent thyroid hormone, triiodothyronine (T_3), is predominantly produced in extrathyroidal tissues by 5′-monodeiodination of phenolic ring of thyroxine (T_4), the hormone that is known to be the prohormone of the former[2]. Although 5′-D enzyme system is present in almost all tissues, liver and kidney are known to have the highest T_4 to T_3 conversion activity[3]. Regulation of the 5′-monodeiodination in pe-

ripheral tissues is an important control point with respect to thyroid hormone action[4].

Lead is being increasingly recognized as an important environmental contaminant[5,6]. Many animal studies have been carried out on the toxic effects of this metal, particularly on hemopoietic, nervous, renal, cardiovascular and reproductive systems[7–10]. However, its effect on thyroid function has received very little attention of the scientists. That too, they are mostly based on simple thyroidal histology and ^{131}I uptake studies in mammal and fish[11,12]. Until today, not a single report is available on the lead-induced alteration of 5′-monodeiodination in any animal model. In the present investigation an experiment was conducted to reveal lead-induced alteration in hepatic 5′-D activity, if any, in cockerel. In addition, changes in serum T_3 and T_4 concentrations were also studied to reveal the thyroid dysfunction.

One-day-old broiler chicks were purchased from a local supplier and were acclimatized to standard laboratory conditions (14L:10D, 27 ± 1°C) for seven days. They were provided with commercial grower feed and water *ad libitum* throughout the experiment.

The birds were divided into two groups of eight birds each. Group I birds, receiving 0.1 ml of distilled water served as control. Group II birds were administered lead nitrate (1.5 mg/bird/day) subcutaneously and the treatment was continued for 30 days. The dose and the number of days were chosen from the earlier studies[13–15]. On the last day, blood was collected and the serum stored at –20°C for the estimation of T_3 and T_4 concentrations. They were estimated by the radioimmunoassay (RIA) method as described earlier, with little modification[16]. RIA kits were purchased from Bhabha Atomic Research Centre, Bombay. The lowest detection limit for T_3 assay was 0.05 ng/ml and for T_4 0.01 ng/ml. Interassay coefficient of variation was less than 5% for both the hormones.

5′-D was estimated by the method of Decuypere *et al.*[17] with little modification. The birds were sacrificed and the liver of each animal was removed and homogenized in 4 volumes (wt/vol) of phosphate buffer (0.15 M, pH 6.5, with 0.25 M sucrose and 5 mM EDTA). After centrifugation at 2000 *g* for 30 min at 4°C, the supernatant was incubated with T_4 (400 µM) and dithiothreitol (DTT, 4 mM) for 60 min. The reaction was stopped by the addition of 95% ethanol. The amount of T_3 generated was measured by RIA. Generation of T_3 was expressed as ng of T_3 generated per hour of incubation per mg protein. Liver protein was estimated by the method of Lowry *et al.*[18].

The data were expressed as mean ± SE. Significance level between two groups was calculated using Student's *t* test.

The results (Figure 1) clearly indicate lead-induced inhibition of hepatic 5′-D activity. Lead also decreased serum T_3 and marginally increased serum T_4 concentrations.

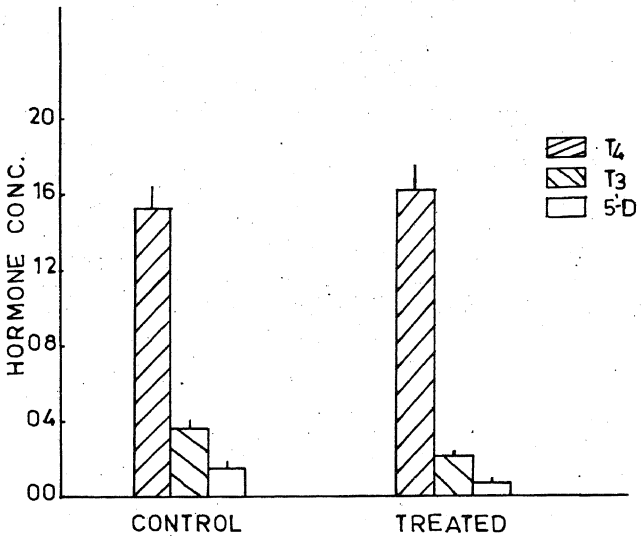

Figure. 1. Effects of lead nitrate (1.5 mg/bird/day) for 30 days on serum T_3, T_4 concentration (ng/ml) and on hepatic type I-5′-D enzyme activity (ng T_3 generated/h/mg protein) in cockerel. Vertical lines indicate the standard error of the means.

Earlier report in rat also shows a slight increase in serum T_4 concentration but a significant decrease in serum T_3 following the treatment of another heavy metal, i.e. cadmium[19]. Lead is known to induce inhibition of thyroidal iodine uptake in rats[20] and in adult patients[21]. Although at present, few reports are available on the effects of lead on thyroid function in mammals[22,23], not a single report is available on lead-induced alteration in 5′-D activity in any of the animal models. Particularly in birds, practically nothing is known on the lead-induced alterations in thyroid metabolism.

In the present study, a marginal increase in serum T_4 and a significant decrease in serum T_3, the most potent metabolic hormone, was observed following lead treatment in cockerel. The marginal increase in the serum T_4 concentration may be due to the inhibited 5′-monodeiodination (catabolism) of T_4 to T_3. This increase was not significant probably because T_4 was utilized in the other metabolic pathways[24–26]. The lead-induced decrease in serum T_3 concentration was further supported by the inhibition of 5′-D enzyme activity that is responsible for the conversion of T_4 to T_3. Earlier reports on cadmium- and mercury-induced inhibition of 5′-D in rat also support our findings[19,27].

Type I-5′-D is a sulphydryl (–SH) group-bearing enzyme and contains selenocysteine at its active site[28]. Lead has been found to inhibit a number of enzymes by either binding to its active site or to the free –SH groups of the enzyme[29,30]. Therefore, in the present study two possibilities exist for the metal-induced inhibition of 5′-D enzyme activity. Either lead replaces selenium in the enzyme or it combines with the free –SH groups, which are essential for the enzyme function, thus making it inactive.

In the present experiment, whatever may be the mechanism of action of lead on hepatic type I-5′-D enzyme, our findings for the first time reveal clearly lead-induced inhibition of the aforesaid enzyme in an avian model.

Speaking Minds: Interviews with Twenty Eminent Cognitive Scientists. P. Baumgartner & Sabin Payr, eds. Princeton University Press, Princeton. 1995.

The realization that living organisms are really information-processing systems and, therefore, the proper framework for the study of their behaviour is the information processing (i.e. computational) framework, has brought about a major revolution in the West in traditional academic disciplines such as psychology, linguistics, education, anthropology, and even sociology. The information-processing framework as a conceptual and theorizing framework, and computer simulation studies as laboratory techniques for evaluating partially articulated theories, have been playing essential roles in drawing several of these traditional disciplines together and giving rise to interdisciplinary programmes of far-reaching consequence. Two such programmes that are beginning to have major impacts on behavioural studies are: Cognitive Sciences Programme and Neurosciences Programme.

Gardner[1] presents a very readable and a detailed historical account of the development of cognitive science which he refers to as 'the mind's new science'. According to his account, the core disciplines constituting cognitive science are: psychology, philosophy, artificial intelligence/computer science, linguistics, neurosciences, and anthropology. Gardner's definition of cognitive science is used as a guideline by the editors of *Speaking Minds*, a book of interviews with 20 academic research scientists identified as 'eminent cognitive scientists'. All the interviewees are from the United States. Their names, disciplines and institutional affiliations are as follows.

Philosophy: Patricia & Paul Churchland (UCSD); D. Dennett (Tufts); H. Dreyfus (UCB); J. Fodor (Rutgers); J. Haughland (Pittsburgh); J. Searle (UCB).
Computer Science: A. Newell (CMU: deceased): H. Simon (CMU); S. Weizenbaum (MIT: retired); R. Wilenski (UCB); T. Winograd (Stanford); L. Zadeh (UCB).
Psychology/Biology: J. McClelland (CMU); S. Palmer (UCB); D. Rumelhart (Stanford): T.Sejnowski (UCSD).
Linguistics: G. Lakoff (UCB).
Math Logic: H. Putnam (Harvard).
Sociology: A. Cicourel (UCSD).
(Note: UC, University of California; B, Berkeley; SD, San Diego; CMU, Carnegie Mellon University)

The choice of persons to be interviewed seems to have been based as much on logistic factors such as time, travel budget, availability of interviewees at the time fixed for the visits, and so on, as on the work in cognitive science these persons are engaged in and the centrality of the role they are playing in the development of this interdisciplinary field.

'Why a book of interviews?' The editors claim 'This dynamic personal discussion seemed to us – at least in some respects – much more powerful and concrete than the more general, and often more moderate and balanced, considerations in the written publications of the same scientists'. However, there are major difficulties with an interview format of the kind the editors have chosen, especially when, as in this case, the person conducting the interview is not himself/herself a practising scientist in the field being discussed critically. The most that can be done is to opt for a somewhat gossipy approach to the issues: 'So-and-So says such–and-such, what is your view on that?' or, alternatively, 'What is your view on such-and-such a controversy?', and so on.

Issues like 'Turing test', 'the chinese–room argument', 'connectionism versus physical symbol system approach', 'whether AI has made (is making) progress or is becoming irrelevant', and so on, lend themselves readily to a format of this kind – especially where the interviewees are academic philosophers with interest in AI and cognitive science. 'Listening' to arguments (gossip?) at a personal level on such issues is illuminating (or even fun) only to the extent the persons involved in the dialogue are interesting personalities in themselves. Unfortunately, this is not always the case and the dialogue pretty soon becomes rather repetitive and tiresome (especially if the personal views being thrown around are already well known to the practioners in the field). To outsiders, quite often, the discussions are likely to be of no value unless they are already 'literate' about the issues being argued about. The editors have tried to help by appending a reasonably detailed glossary of terminology. Another helpful gesture is a reading list of his/her own publications suggested by each interviewee.

In my opinion the participants in the discussions have thrown away a good opportunity to 'educate' aspiring entrants to the field of cognitive science, as well as outsiders, about the really *deep* problems that need to be addressed if cognitive science is to make any substantive contribution to our understanding of the agentive aspects of agents and how the brain/mind plays its central integrating role to enable agents to behave the way they do. What are the deep technical (i.e. computational) and theoretical (*not* philosophical) issues that need to be addressed in understanding vision, language behaviour, perception, motor behaviour (e.g. object manipulation, navigation, controlling body movements. maintaining balance, etc)? What new issues arise when behaviour involving two or more of these modalities has to be deployed to achieve some given end? Babies, only a few months old, have been shown to be capable of imitating facial expressions they are exposed to. How do they achieve this (especially since they cannot watch their own faces)? We still do not know how to construct a robot that can watch somebody else (or another robot) going through an assembly operation and imitate it. Young children are capable of accomplishing this. What are the computational issues involved here?

There are some discussions in the book about how to build up interdisciplinary programmes and why such programmes are generally more successful in the United States than elsewhere – Europe, for example. These discussions are of some relevance in the Indian context, in that in our universities (and elsewhere too) the disciplinary walls continue to remain as thick and impenetrable as ever. It may be useful to close this review with the following remarks by Patricia Churchland on why she chose to go to UCSD:

'The cognitive science community here . . . is large, diverse and lively. At some point or other, everybody passes through, so there is lots of contact, and that means there is opportunity to learn

a lot and keep abstract of new developments. There is also considerable interest and activity in computational neuroscience, so I feel much at home. I am an adjunct at the Salk Institute, and I currently work in . . . Sejnowski's laboratory. The lab has tea every afternoon, and various people drop by – often Francis Crick, and some of the visual psychologists, such as Ramachandran – and we discuss everything from consciousness and free will to apparent motion to NMDA receptor.'

Development of Ideas in Physics. Nils Ryde. Almqvist & Wiksell International, P. O. Box 4627, Alsnogatan 7, S-116, 91, Stockholm, Sweden. 196 pp. Price: Not known.

The rapid strides made during the first half of this century and a little earlier, have been the subject of numerous books in physics. Indeed, for several decades now, an introductory description of this area commonly known as 'Modern Physics' is an integral part of undergraduate physics curriculum in every university. It includes topics such as the discovery of electron and atomic nucleus, optical and X-ray spectroscopy, discovery of electron spin, neutron, nuclear fission and fusion and introductory quantum mechanics. The well-known textbook by Richtmyer, Kennard (and Cooper in later editions) gives an excellent exposition of these topics. Recent textbooks on modern physics like the one by Kenneth Krane also include more contemporary topics such as nucleosynthesis in stars, quark model of elementary particles and so on.

This book is a collection of a dozen partly didactic and partly historical essays on topics in modern physics. The author has been a participant in the events that unfolded in the 'golden age of physics', and his familiarity with them comes through clearly in his writing. His prose is direct and unostentatious. Most of the essays are well written, especially the ones on 'optical spectroscopy' and 'origin of the elements'. Some, however, are sketchy and need additional material for completeness (for example, the essay on matter and antimatter). The narration could have been made much more interesting with some illustrations and biographical sidelights on the main characters of the story. The quality of production is good, though a few errors remain. (For example, eq. (12) on p. 37 and eq. (21) on p. 44 contain printing errors.)

The main limitation of the book is that the essays are too 'dense' in the subject matter to be comprehensible to a beginning student. For example, in the space of some 15 pages, the author describes the rise of quantum mechanics from Heisenberg's 'arrays', deBroglie's matter waves to the successful QED explanation of the Lamb Shift in hydrogen. Such a compact description is obviously suitable only for those who are already broadly familiar with the theme. Despite this, the book does fill a certain need, since the more authoritative and complete historical accounts of modern physics (such as *The Conceptual Development of Quantum Mechanics* by Max Jammer and *Inward Bound* by Abraham Pais) are too expansive to be read with ease. The book provides short and useful historical summaries of several interesting topics, which teachers and physicists can profitably use for enrichment and recapitulation of what they already know.

A Modern Introduction to Ancient Indian Mathematics. T. S. Bhanu Murthy. Wiley Eastern Ltd., New Delhi, 1992, 214 pp. Price: Not mentioned.
Indian Mathematics and Astronomy. S. Balachandra Rao, Jnana Deep Publications, 2388, 13th Main, A-Block, Rajajinagar, II Stage, Bangalore 560 012, India. 1994. 234 pp. Price: Rs 75, $17.00.

A man is known by the company he keeps. I suppose a similar statement holds for books as well. One of the books under review (*A Modern Introduction to Ancient Indian Mathematics*) suffers because of its unqualified association with Swami Bharati Krishna Tirtha's *Vedic Mathematics*. The author mentions in the preface that the initial purpose of the book was to present proofs of certain propositions stated in *Vedic Mathematics*, thus subtly authenticating it. (It is more an error of omission than of commission as he fails to warn the readers about the doubts expressed by scholars in respect of many of Swamiji's claims.) First, a few words about *Vedic Mathematics*. It is more or less established that its contents are not of vedic origin (the Swamiji has failed to produce a reliable reference) and its mathematical contents do not, by a long chalk, justify the tall claims made in the book. Take the example of the algorithm to write down the decimal expansion of reciprocals of certain integers. As has been pointed out by S. G. Dani in his excellent two-part article ('Myths and Reality – On Vedic Mathematics', *Frontline*, 22 October 1993 and 5 November 1993), there is no evidence in the available vedic works or even in the works of other Indian mathematicians for over 2000 years later, of any knowledge of writing a fraction in decimal form. Unfortunately, this is one of the propositions Bhanu Murthy chooses to prove in his book.

Apart from these proofs (of Swamiji's propositions), Bhanu Murthy's book contains a well-written account of the *Pell's* equation (which he prefers to refer to as Brahmagupta–Bhaskara equation). There is also a chapter entitled 'Selected Topics in Geometry' and the reviewer fails to understand why some of the topics which are featured are there at all; for instance, Morley's theorem [which would have had some meaning at least if he had given the elegant proof due to M. T. Naraniengar in 1909 (see *Geometry Revisited*, Coxeter and Greitzer)].

On the other hand S. Balachandra Rao's book, *Indian Mathematics and Astronomy*, provides a good introduction to the development of mathematics and astronomy in India since vedic times. Each mathematician's contribution is preceded by a discussion on his place and times according to available records. In fact, one of the praiseworthy features is that statements made are justified with references and different viewpoints are sincerely reproduced. There is an excellent bibliography at the end.

One of the main points that Balachandra Rao (as also Bhanu Murthy) wants to emphasize is that it is not true, as is generally believed, that Indian mathematics entered a dark age after Bhaskara II (*ca* 1120 AD). There were substantial contributions even after him, specially by the Kerala school. In fact, to quote Dani '... The sustained development of mathematics in India in the post-Greek period was indirectly instrumental in the revival in Europe after its "dark ages" '.

Though the achievements of mathematicians in ancient India may look impressive, there were serious deficiencies also. They have noticed that π cannot be calculated exactly but nothing seems to have been done to investigate this aspect further in contrast to the amount of time and effort that have gone into *squaring the circle* in the Greek civilization. Indian mathematicians have handled surds with ease but the notion of irrational numbers escaped them. The deductive reasoning which characterized the Greek mathematics and which really gave the impetus for the phenomenal development of mathematics outside India is conspicuous by its absence in Indian mathematics. Another significant factor which impeded the progress was that mathematics mostly served as the hand-maid of astronomy whose needs it soon outgrew. One also has to consider the fact that physics had not developed much, since it was in trying to answer the needs of physics that calculus was discovered and several other areas of mathematics developed. As Balachandra Rao rightly observes, the perfection to which Indian logic (tarka) was developed seems to have had no influence on the thinking of ancient Indian mathematicians. To quote him further: 'The over-emphasis on utilitarianism of mathematics seems to have had unfortunate results in the development of the subject in this country... The nonchalance with which the splendid achievements of the Greek geometry were ignored while the pseudoscience of Greek and Babylonian astrology was received with open arms is indeed the worst of these.'

For further serious study of history of mathematics in India it is very much necessary to bring out authoritative translations of the original works. For most of them the translations available are more than 60 years old and so do not have the benefit of research done on the subject in recent times, which is quite substantial. Also, some positive attempts should be made to educate the public about the facts concerning *Vedic Mathematics*. It has acquired a large following and there are even correspondence courses on the subject! There is a danger, a very real one at that, of this having undesirable consequences on mathematics education in our country. Already the Uttar Pradesh government has introduced 'vedic mathematics' in school textbooks based on the Swamiji's book. While it is important to create an awareness of our past achievements (based on authentic sources) it is also necessary to confront and expose baseless constructs such as these.

Leks. Jacob Hoglund and Rauno V. Alatalo. Princeton University Press, 41 Williams Street, Princeton, New Jersey 08540, USA. 1995. 248 pp. Price: Not known.

Blazes of swarming fireflies in the woods, synchronized arm-waving of fiddler crabs on estuarine mudflats, incessant nocturnal choruses of crickets, katydids and frogs/toads in our neighbourhoods and dancing peacocks are familiar yearly events in India. These male aggregations are meant to attract females for the purpose of mating. However, not all these events are treated in the strict sense as 'lekking'.

Lekking has been defined as 'males aggregating for the purpose of mating'. In lekking animals the male's contribution to parental care is none, females have the option of mating with males of their choice and female gathering on the leks is not a response to some resource such as food or ideal breeding site that the male actively defends. Thus by the above definition, many mating aggregations of animals such as that of fiddler crabs, some fishes and frogs cannot be treated as typical lekking, as males of these animals are known to defend egg deposition sites simultaneously as they display.

Almost 200 years ago, naturalists observed and reported mating aggregations on natural 'arenas' in vertebrate animals. Somewhere in the late 1800s, the term 'lek' was first coined to describe the arena and 'lekking' for the rather deviant mating system. Lekking is now reported in many groups of lower organisms including insects and spiders. Nevertheless, the most typical and well-studied forms of lekking are those that the birds and a few ungulate mammals demonstrate. And probably the most intensively studied of animals is the temperate sage grouse, a galliform bird that mates on leks throughout its range.

Field study of animal behaviour has not gained the same momentum in India as it has in the western world. In India there have been some attempts to study the breeding ecology and behaviour of animals in the field starting with Salim Ali's work on the weaverbirds in the nineteen thirties. Although there have been a few casual reports of lekking in peacocks and blackbucks in the past, the only real attempt to study the ecology of lekking in Indian animals *in situ* is a recent Master of Science dissertation from the Wildlife Institute of India, Dehra Dun. This rather illuminating piece of work on lekking blackbucks in north-western India is however unpublished.

The book under review is easily the most complete treatise on this special subject relating to animal mating systems in recent times. It is written in a very simple and readable style. The authors have been considerate in keeping the more complex mathematical modelling as a latter chapter without depriving the uninitiated reader the pleasure of going through the book.

The organisms listed as observed lekking in chapter 2 are surprisingly many and spread across taxonomic groups. Taking a variety of general and detailed case studies from this spectrum of animals, the authors discuss the broad causal factors of lekking. Although detailed discussions of sexual selection, female mating strategies and a number of models that attempt to explain the advantages and disadvantages of lekking, including predation risk, sharing information, etc., are invoked, what ultimately perplexes the reader is the fact that there has not been one gen-

eral governing principle that has hitherto been identified without ambiguity.

Lekking has best evolved in birds. Interestingly, of the nearly 100 species of birds (as listed in the book) in which this behaviour has been documented/studied in detail, 78% are forest birds, especially tropical, as that in families Paradiseidae (New Guinea/ Australasia), Cotingidae and Pipridae (both Neotropical). Similarly, it is noteworthy that 62% and 20% of all lekking birds belong to the New World and Australasia respectively. These patterns are suggestive enough to start speculating the role of biogeography and habitat on the origins of this particular mating system, at least in birds.

Tropical rainforests in New Guinea and America are very dense and dark within. Male birds of paradise, cotingas and manakins with their elaborate and strikingly irridescent plumage will certainly attract females better by aggregating and displaying than being solitary. Although related ideas, viz. 'visual stimulus' and 'passive attraction' to females offered by aggregating males have been addressed and dismissed as causal factors in the book, these ideas have not been put to good test in the tropics.

Whether this behaviour is 'relict' in animals has not been addressed in the book. Considering the biogeographical and habitat-related pattern of distribution of lekking behaviour in birds, it is also tempting to invoke the argument of patchy habitat availability in the tropics during the Pleistocene glaciations. Works in the early 1970s and 1980s have discussed the possible influences that reduced availability of forest habitats had on the diversity and speciation of neotropical birds. If reduced habitat availability had forced breeding birds to aggregate and display during the long periods of climatic fluctuations, such traits could not have been eliminated during the last 10,000 more or less steadily warm years. When ecology fails to explain an observed pattern in nature, scientists have resorted to history. The book under review fails to do this.

More examples of birds, especially the migratory waders such as snipes and ruff/reeve in which lekking is reported, are compelling enough to invoke historical explanations to the origin and persistence of lekking. Migration in birds is itself considered a climate change-induced relict behaviour. Future studies should probably look at the lower animals, especially the invertebrates in the light of the existing theories on lekking, not ignoring the importance of history. Any further knowledge on animal mating systems will not only be of academic interest but of great value in the conservation of biodiversity.

Samanta Chandra Sekhar: Life and work

P. C. Naik and L. Satpathy

Mahamahopadhyaya Sri Chandra Sekhar Simha Hari Chandan Mahapatra Samanta (1835–1904), generally known as Samanta Chandra Sekhar and more popularly as Pathani Samanta in Orissa, worked in astronomy following the traditional methods and composed a treatise entitled 'Siddhanta Darpana' in Sanskrit verse. It is a valuable work that records innumerable improvements over the ancient classics, namely, 'Surya Siddhanta' and 'Siddhanta Siromani', by incorporating original observations, calculations, instrumentation and theories. The aim of this paper is to outline and bring to the notice of a wider audience the genius of Chandra Sekhar and his contribution to astronomy. In addition, we also present a brief life-sketch of the astronomer.

India has a rich heritage of astronomy having produced great astronomers like Aryabhata, Varahamihira, Brahmagupta and Bhaskara. The genius of these luminaries bloomed at various places spread all over the country, scaling a time span of nearly 1500 years beginning with 5th century AD. Mahamahopadhyaya Chandra Sekhar Simha Harichandan Mahapatra Samanta, referred to hereafter as Samanta Chandra Sekhar, seems to be the last link of this long order of great Hindu astronomers. *Surya Siddhanta*, *Aryabhatiya*, *Panca Siddhantika*, *Brahmasphuta Siddhanta* and *Siddhanta Siromani* are prominent among the numerous astronomical works of our illustrious ancestors. *Siddhanta Darpana*[1], composed by Samanta Chandra Sekhar, looks to be the latest valuable classic of high order. It is a systematic record of Samanta's lifelong research in astronomy with substantial original contribution to the field. The treatise, written in beautiful Sanskrit verse after the time-honoured Hindu tradition, has great scientific value and is also a fine piece of literary work.

Chandra Sekhar was born in the royal family of one of the princely states of Orissa, at Khandapara in 1835. He is also fondly called Pathani Samanta in the state. Chandra Sekhar, when a child, was initiated to identify stars by his father. He received primary education from a Brahmin teacher. Thereafter, he started teaching himself *Lilavati*, *Bijaganita*, *Jyotisha*, *Siddhanta*, *Vyakaran* and *Kavya* using his family library. He was more attracted by mathematics and astronomy.

At the age of fifteen, he began to check the predictions of the *Siddhantas* with his observations. Ancient Indian works do not give details of instruments or methods of measurement explicitly, excepting hints here and there. So young Chandra Sekhar devised his own instruments. He noticed that, even classics like *Siddhanta Siromani* of Bhaskara and *Surya Siddhanta* did not agree with his observations, for the stars and planets did not appear in the sky as per their predictions.

Hence, young Chandra Sekhar assigned the job to himself and set out for observations night and day, checking every figure occurring in the earlier works.

He began recording his observations and formulations at the age of 23, and in the form of treatise, two years later. The manuscript of *Siddhanta Darpana* was ready in 1869 when he was 34. But it took another 30 years for the work, originally written on palm leaves in Oriya characters, to appear in Devanagari script printed on paper in 1899. Chandra Sekhar had *Surya Siddhanta* for his prime reference and *Siddhanta Siromani* as his guide.

This remarkable scholar and scientist, being confined to a small hilly state in a remote corner of Orissa, far away from the sphere of English education, was virtually doomed to obscurity but for his chance acquaintance with Mahesh Chandra Nyayaratna, Principal of Sanskrit College, Calcutta, who probably later on introduced him to Jogesh Chandra Ray of Cuttack College (today's Ravenshaw College). Nyayaratna's efforts[2] brought him the title of Mahamahopadhyaya, conferred by the British Government in 1893.

Ray was the key person under whose supervision and involvement *Siddhanta Darpana* was published in 1899 from Calcutta with the financial support of the kings of Athmallik and Mayurbhanj. It must be noted that the scholarly introduction of 56 pages in English therein by Ray[3] formed the window through which the outside world could get a glimpse of the valuable treasures contained in this monumental work couched in hardly accessible Sanskrit verse. The international journals *Nature*[4] and *Knowledge*[5] acknowledged the greatness of this contribution to astronomy by Chandra Sekhar and eulogized him in glowing terms. This Sanskrit classic underwent two Oriya translations[6,7] in 1975 and 1976. We present in the following a brief discussion of this work citing only a few important original contributions of its author.

Siddhanta Darpana

Chandra Sekhar in the 17th *Sloka* of the first chapter of the treatise enumerates the requisite characteristics of a *Siddhanta*. The work that deals with the theoretical division of time from the smallest unit of *Truti* (0.274348×10^{-6} s)

Table 1. Summary of the contents of *Siddhanta Darpana*

Name of section	Chapter number	Chapter content	Number of *Slokas* in the chapter
Madhymadhikara	1	Description of time	55
	2	Description of *Bhagan*, etc.	25
	3	Mean planet positions	77
	4	Various corrections	57
Sphutadhikara	5	True planet positions	221

	24	Conclusion	156
Total			**2500**

to *Pralaya* (10^{13} solar years), along with the motion of the celestial objects, their rotations, orbits, alignments, occultation and eclipses, etc., with the relevant mathematics like algebra, arithmetic, geometry and trigonometry and also concerns with the question of the origin of the universe is called a *Siddhanta*. One will notice that *Siddhanta Darpana* with 24 chapters and 2500 *Slokas*, out of which 2284 are Samanta's own composition and 216 are citations from the ealier authors, falls short of none of these qualifications. Chandra Sekhar has made original contributions to most of the aforesaid topics dealt with in his astronomical treatise.

It will not be out of place here to give a brief contentwise description of *Siddhanta Darpana*. It is broadly divided into two parts, viz. *Purvardha* (first half) and *Uttarardha* (latter half). The first half contains 15 chapters and the latter half 9. The chapters are further grouped under five sections, namely, *Madhyadhikara*, *Sphutadhikara*, *Triprasnadhikara*, *Goladhikara* and *Kaladhikara*. The first two sections deal with the mean motion and the true positions of the planets, respectively. The third section deals with motion described in terms of space, time and direction. The fourth section gives an account of the relevant mathematics like spherical trigonometry and geometry, etc. The fifth section describes different ways of reckoning time. The distribution of chapters and *Slokas* along with the title of the topic dealt with in each chapter, is given in Table 1.

The contents of *Siddhanta Darpana* look amazing as the achievement of a single mind. Chandra Sekhar has observed, verified and corrected wherever necessary all that was known to the Hindu astronomers for thousands of years. Very often he has gone beyond them to discover new phenomena and to give new formulations and comes out with predictions supposed to remain valid for at least 10,000 years to come. We give below an outline of his contributions to the four important aspects of astronomy, namely (i) observation, (ii) calculation, (iii) method of measurement and instrumentation and (iv) theory and model.

Observation

As indicated in the introduction, the discrepancy between predictions of the ancient *Siddhantas* and his own observations prompted Chandra Sekhar to embark upon serious investigation. He has made it clear that, apart from purely theoretical questions, nothing has been recorded in the *Darpana* without verification through observations.

In the third chapter of the treatise, Samanta enters into discussion on the planets. Let us look at the sidereal periods (time taken for a complete revolution with respect to 'a fixed' star) of the planets as ascertained by him. For comparison, the periods given in *Surya Siddhanta* and *Siddhanta Siromani*, the

Table 2. Sidereal periods of the planets in mean solar days. The data in the last column are taken from ref. 19 and the remaining ones from refs 3 and 20

Planet	*Surya Siddhanta*	*Siddhanta Siromani*	*Siddhanta Darpana*	European values as in 1899	Modern values
Sun	365.25875	365.25843	365.25875	365.25637	365.25636

Moon	5 2 46	5 1 10	6 3 41

European values as known in 1899, and the modern ones are presented side by side in Table 2. It may be noted that Chandra Sekhar has arrived at the same values for the periods of the sun and the moon as in *Surya Siddhanta*, which agree with the modern values up to second and third decimal places, respectively. But in the case of the slow-moving planets like Jupiter and Saturn, his results are surprisingly in closer agreement with the modern values than those of the other two *Siddhantas*. Table 3 gives a comparison of the mean inclination of the orbits of the planets to the ecliptic. It can be seen that, of the three classical works quoted here the values of *Siddhanta Darpana* are the closest to those of modern astronomy.

The angular position of a planet in its orbit, with respect to the force centre, is called the 'true anomaly'. The eccentric angle of the planet on the auxiliary circle is the 'eccentric anomaly'. Their difference is the equation of anomaly, the greatest value of which is a measure of eccentricity. The greatest equations given by Samanta in the case of the sun and the moon agree within seconds with the Western astronomy (Table 4). The intersection positions of the moon's orbit with the ecliptic are called *Rahu* and *Ketu* in the traditional Indian astronomy. In the Western astronomy they are called the nodes of moon. The minimum distance position of the moon from the earth is called the *perigee*. Table 5 shows a comparison of the sidereal periods of these nodes and the perigee.

Further, Chandra Sekhar gives a correction to be applied to *Mandocca* (the farthest position on the orbit from the force centre) of Mercury, Mars and Saturn and calls it '*Parocca correction*'. The maximum values of these corrections are 12°20′, 7°30′ and 5° for the above three planets, respectively.

In observation of the moon, Samanta Chandra Sekhar noticed three important irregularities. They are *Tungantara* (evection), *Pakshika* (variation) and *Digamsa* (annual equation). In terms of modern understanding[8,9], recognition of these three irregularities is as follows:

(i) *Tungantara* (evection) is the largest of the irregularities. It depends on the changing position of the apse line (the line joining the maximum and the minimum distance positions from the force centre, i.e. the earth) in successive lunar months. It further has the following two effects:

(a) The apse line advances as a whole while undergoing oscillatory motion. However, it retrogrades when the perigee (maximum distance from the earth) occurs at the first and third quarters of a lunar month.

(b) The eccentricity also oscillates, attaining a maximum of 0.066, when perigee occurs at new or full moon, and a minimum of 0.044, when it occurs at first or third quarter. This perturbation effectively puts the moon forward or backward from the expected position by about a degree. The maximum of this irregularity according to modern astronomy is 1°17′, whereas Samanta Chandra Sekhar observed it to be at most 2°40′.

(ii) *Pakshika* (variation): From new moon to full moon, i.e. during the bright fortnight of the lunar month, the attractive force of the sun on the moon retards it. And during the dark fortnight, the effect is opposite and the moon is accelerated. This causes a maximum shift in the position of the moon by 39′31″ according to modern astronomy. Samanta's value of 38′12″ for maximum of this effect is surprisingly close to the modern value.

(iii) *Digamsa* (annual equation): This is another irregularity in the position of the moon, which arises due to variation in sun–moon distance as the earth orbits round the sun. Obviously, its period is one year. The maximum value of this correction is 11′9″ as per modern astronomy, and Samanta's value of 12′ is fairly close to it.

Chandra Sekhar has clearly mentioned in *Siddhanta Darpana* that *Tungantara* was known to his predecessors. However, J. C. Ray in his introduction to *Siddhanta Darpana* says: 'In computing the moon's place, Chandra Sekhar has discovered some original corrections – original in the sense of their having been unknown to the ancient astronomers of our country'[3]. Even Burgess[10] in his English translation of *Surya Siddhanta* says that the Hindus did not take any notice of evection. However, the latest view on this issue is that of P. C. Sengupta[11], who concludes that evection and variation were introduced by Munjala and Bhaskara. Nevertheless, it is definite that Samanta Chandra Sekhar was the only Indian astronomer of traditional school to have discovered *Digamsa* and took into account all the three irregularities and measured them with utmost accuracy. In passing, it will not be out of place to mention that Tycho Brahe was the first

Table 5. Sidereal periods of the nodes (*Rahu* and *Ketu*) and the perigee in mean solar days (see text). The data in the last column are taken from ref. 19 and the remaining ones from refs 3 and 20

Entity	*Surya Siddhanta*	*Siddhanta Siromani*	*Siddhanta Darpana*	European values as in 1899	Modern values
Moon's nodes	6794.3948	6793.2535	6792.644	6789.270	6793.470

		0 30 10.8055	0 03 10.7946631769

Western astronomer to have detected and measured all these three irregularities.

Another improvement made by Chandra Sekhar was in the case of parallaxes of sun and moon. Parallax is defined as the angle subtended by the radius of the earth at a heavenly body. The earlier *Siddhantas* took it to be 3′56″at sun and 52′42″at moon. But since these are the quantities that enter into calculation of eclipses, Chandra Sekhar changed them to make the predictions agree with the observations. The ancient Indian astronomers place the sun at a distance not more than 14 times that of the moon from the earth. Chandra Sekhar hiked this ratio by more than ten times, to 154, which is much closer to the modern value of 390.

Calculation

Astronomy is a science in which observation goes hand in hand with calculation. Besides a thorough knowledge of the motion of the celestial objects, it requires sufficient computational skill to tackle the vast multitude of big numbers We will see in this section that Chandra Sekhar was extraordinary in this respect. Very often he has gone beyond his predecessors in precision of computation and in giving new methods of calculation.

To get positions of planets one has to do extremely careful calculations. In the traditional method one first calculates a mean position and then applies corrections to arrive at the true position. The calculation of mean position requires a mean rate of motion. Works in traditional astronomy clearly give these rates as accurately as possible. The earlier works are found to give these rates (mean angular displacements per day) at best to five places in the sexagesimal system. But Chandra Sekhar gives these rates to ten places in the same system. For comparison, we have presented in Table 6 the modern values of these rates in the decimal system and also given the traditional data converted into decimal system.

Chandra Sekhar recognized that, in addition to the usual correction to the mean position, further finer corrections are needed from time to time to make accurate predictions. For each planet, he has provided such a correction to be applied for hundred million (one *Arbuda*) years. There are as many as 55 tables, each on an average having 50 numbers, sometimes given up to five places in sexagesimal system. These tables appear to be a challenge for one's unaided computational skill.

Regarding the measurement of longitudes of the celestial bodies, there is a fundamental difference between the Western system and that of the Hindus. In the former system, it is measured with respect to the vernal equinox, i.e. one of the point of intersection of the celestial equator with the ecliptic. The Hindu system measures it with respect to a fixed point (a particular star) on the ecliptic. It is the starting point of zodiac and its longitude is the *Ayanamsa*. But it may be pointed out that the axis of the earth undergoes a precessional motion with a period of about 25,800 years. This causes a shift in the position of the equinox and also in that of the reference star, which according to the traditional Indian astronomy is called *Ayanacalana*. So, this effect must be taken into account in fixing the *Ayanamsa* of the reference point. A correct determination of the *Ayanamsa* involves a number of factors like the rate of pre-

cession, the exact length of a year, the year of the zero *Ayanamsa* and the star of reference. A critical discussion of the matter is found in the introduction to *Siddhanta Darpana*[3]. *Surya Siddhanta, Soma Siddhanta, Sakalya Siddhanta*, and *Laghu Vasistha*, etc., have given the rate of precession as lying in the range 54″ to 46″.25 per year. However, *Bhasvati* and *Graha Laghava* have found the value to be nearly 60″. But Chandra Sekhar's value is 57.615″ per year.

The modern value of the precessional rate is, however, 50.3″ per year. Thus, it appears that the Indian rates quoted above are in disagreement with the modern value. Therefore, it is desirable to understand how such varying rates of precision which sensitively affect the fixation of *Ayanamsa* could give meaningful prediction in the ancient Indian astronomy. Ray gives a solution to this puzzle. He points out that the Indian astronomers take the sidereal year for calculation of the rate of precession, in contrast to the tropical year, taken in the West. Since the sidereal year is longer by a few minutes, the sun advances by an amount of 8.4″ during this interval of time difference. This has an effect on the calculation of precession of equinox and the amount has to be deducted from the rates given by various authors. When this correction is taken into account, Samanta's value turn out to be 49″.179 per year, which is much closer to the modern value.

Chandra Sekhar has devised a diagramatic or graphical method (*Parilekha*) for calculations of eclipses and many other phenomena. In this method, when the nature and periodicity of the motion of the heavenly bodies are known, one can simulate the phenomena by constructing geometrical diagrams on the plain surface and use them for computation of dynamical quantities. This method might be akin to the numerical evaluation of integrals. Especially, he tackles the calculations of the three well-known irregularities of the moon with simple geometrical arguments. It is needless to say that his calculations of eclipses are accurate and agree with observations. It may be noted here that this has been the guide in the preparation of the almanac used in Orissa since about 1870.

Before concluding this section, we would like to point out at least two facts of mathematical interest from *Siddhanta Darpana*. Samanta does not accept the value of π as 22/7; instead, he takes it to be 3927/1250 and also 600/191. He seems to have provided a new method for computing the cube root of numbers which is different from that of Bhaskara.

Measurement and instrumentation

Chandra Sekhar was unaware of the scientific and technological developments that had already taken place in the West. He had not seen or even heard of a telescope until his very old age. So he employed the traditional methods for astronomical measurements. He had devised some new instruments for the purpose. It is a remarkable point that Jai Singh in the 18th century built a number of observatories in the northern part of the country. His instruments for measurements in these observatories are rather gigantic. In sharp contrast, Chandra Sekhar, who worked about 150 years later, fabricated quite simple and small devices and made accurate observations.

Before attempting to give an account of his astronomical *Yantras*, we would like to mention an interesting fact about Chandra Sekhar's ability for measurements. The children at primary schools in Orissa today read it as a myth that Samanta measured the heights of distant mountains with a pair of tiny sticks. The simplest of his stick instruments is the *Sanku* (pole). Of course, it was used also by the Greeks under the name '*gnomon*'. It is not difficult to find out the latitude of a place by observing the shadow of the *Sanku*, cast by the sun. But more interesting is, Chandra Sekhar's calculation of local time from the shadow.

Chandra Sekhar's most talked of instrument is the *Mana Yantra*. Details of construction of this instrument have been described in *Siddhanta Darpana*. Chandra Sekhar used this *Yantra* as a multipurpose device. A simpler version of this *Yantra* is a two-stick arrangement in the form of 'T', which he could fabricate quickly, and measure the height and distance of mountains, etc., whenever occasion demanded.

Samanta has described in detail the construction techniques for varieties of *Gola-yantra* that he used to measure the positions of planets. There is a mention of as many as ten different devices for measurement of time in *Siddhanta Darpana*. Models of some of these, including a *Gola-yantra* have recently been exhibited at the Regional Science Centre, Bhubaneswar. Samanta Chandra Sekhar has devoted a full chapter of *Siddhanta Darpana* to describing the construction and use of instruments. Such instruments, by today's standard, are crude, but using them he could arrive at results in close agreement with modern values, primarily due to his skill, attained through long years of dedication and practice.

Theory and model

The most prominent of Chandra Sekhar's theoretical contributions is his model of the planetary system, which is different from those of his predecessors in India. Samanta supported a stationary-earth hypothesis, with sun, moon and stars revolving around the earth. But it has the novel feature that planets like Mercury, Venus, Mars, Jupiter and Saturn go around the sun, and the sun moves around the earth together with these companions. This is evident from the following *Slokas* of *Siddhanta Darpana*:

तन्नमध्यम-मार्त्तण्डः परितोमण्डलंभुवः
भ्रमन् ताराखेचराणां कक्षामध्यस्थ उच्यते।
तं भ्रमन्तो महीजाद्यास्तत्सङ्गेन भुवं पुनः
परिक्रामन्ति यत्तस्मात् स प्रोक्तः सर्वकर्षकः।

S. D. Ch. V Slokas 6 and 7

Thus, he assigned heliocentric motion to the planets. Incidentally, a similar model was proposed by Tycho Brahe in the West in the late sixteenth century. A recent work by Ramsubramanian *et al.*[12] brings to light that a similar model of the planetary system was given by Nilakantha Somasutvan of the Kerala school by 1500 AD.

Conclusion

We have attempted to give a brief sketch of the extraordinary life and work of Samanta Chandra Sekhar here. Unfortunately, due to various historical and geographical reasons, his true position in ancient Indian astronomy has not been ascertained so far. Ray has drawn a nice parallelism between the life and works of Samanta Chandra Sekhar and of Tycho Brahe. The journal *Nature* com-

ments[4]: 'Prof. Ray compares the author very properly to Tycho. But we should imagine him to be greater.' The importance of Samanta's work and the quality of his observations with naked eye have got true recognition through the comments made in the journal *Knowledge*[5]: 'Of all the numerous works on astronomy that have been published within the last few years, this is by far the most extraordinary and in some respects the most instructive. ....It is a complete system of astronomy founded upon naked-eye observations only. ....The work is of importance and interest to us Westerners also. It demonstrates the degree of accuracy which was possible in astronomical observation before the invention of telescope.' Here it will be probably fair to state that Samanta Chandra Sekhar belongs to the same class of Indian astronomers as Aryabhata, Varahamihira, Brahmagupta and Bhaskara.

It is unfortunate that Chandra Sekhar is almost unknown outside Orissa. This has so happened probably because he lived and worked during a period which was about 300 years after Orissa lost its pristine glory and preeminent position in the Indian subcontinent[13–16]. Although Orissa came under British rule in 1803, it continued to remain in virtual darkness during the lifetime of Samanta, being deprived of the advantage of modern education.

Almost a century has passed since the publication of *Siddhanta Darpana*. Its author passed away in 1904 living in the midst of poverty and struggle. The only recognition for the scientist during his lifetime was the acceptance of his astronomical prescriptions for regulation of the rituals at the Jagannath temple and the award of the title of Harichandan Mahapatra by Gajpati king of Puri in 1870. Of course, the title of Mahamahopadhyaya was conferred upon him by the British Government in 1893.

It is a matter of some relief that Kochhar and Narlikar[17] and SriRam[18] have recently referred to the work of Samanta Chandra Sekhar. Nevertheless, *Siddhanta Darpana* continues to serve the people of Orissa by providing the basis for the preparation of its almanac.

ACKNOWLEDGEMENTS. The English introduction to *Siddhanta Darpana* by J. C. Ray and the Oriya Translation of the Treatise by Pandit Bira Hanuman Shastri have been our prime source of reference in preparation of this article. We are grateful to Dr Ranatosh Chakrabarti of the Department of Physiology of Surendranath College, Calcutta, for having been kind enough to provide us with the copies of the articles on Samanta Chandra Sekhar from *Nature* 1899 and *Knowledge* 1899. We are thankful to Dr S. Torasia for his cooperation and encouragement.

P. C. Naik is in the Pathani Samanta Planetarium, Bhubaneswar 751 013, India and L. Satpathy is in the Institute of Physics, Bhubaneswar 751 005, India.

INSTITUTE FOR PLASMA RESEARCH

(An Autonomous Institute of DST, Govt. of India)
Near Indira Bridge, Gandhinagar Highway,
BHAT, GANDHINAGAR 382 424

ADVT. NO. 08/95

FACULTY AND POST-DOCTORAL POSITIONS IN PLASMA PROCESSING

The Institute for Plasma Research is an autonomous research institute established by the Department of Science and Technology, Govt. of India to lead the country's Plasma Physics and Magnetic Confinement Fusion Research Programme.

The Plasma Processing Group of IPR is involved in the development of advanced plasma-assisted material processing technologies for the Indian industry. The group interacts with industry through all the phases of technology generation; from conception to commercialization. It is a multidisciplinary activity and hence provides considerable scope for exposure to different areas of specialization.

Plasma processing is an emergent technology which utilizes exotic properties of the plasma state to effect physical, chemical and metallurgical transformation in materials to produce new materials or impart new properties to conventional materials. Plasma processing has already entered the industrial arena in advanced countries.

The Plasma Processing Group of the Institute for Plasma Research exploits the IPR expertise plasma and allied technologies in developing plasma-assisted material processing technologies for Indian industries. PPG interacts closely with entrepreneurs through all the phases of technology generation and transfer from concept to commercialization. A technology demonstration facility and a surface and material characterization facility with many advanced instruments are being set up.

FACULTY AND POST-DOCTORAL POSITIONS

The PPG invites applications for the post of Associate Professor – I, Fellow/Scientist – SD and Post Doctoral Fellows. The specific projects on which they would be working are:

1. Development of processes and techniques in plasma-assisted pyrometallurgy and mineral processing.
2. Plasma-based synthesis of ceramic and metal powders of industrial relevance.
3. Development of multi-function surface engineering techniques and systems.
4. Plasma source ion-implantation techniques and material evaluation.

Qualification and Experience: Ph D with adequate research experience in high voltage techniques, surface sciences, ceramics, process and physical metallurgy and related areas to contribute to the research and development programmes.

GENERAL INFORMATION

Scale of Pay :

1. Associate Professor – I	:	Rs. 3700–125–4700–150–5000 (Gross Rs. 9730/-)
2. Fellow/Scientist – SD	:	Rs. 3000–100–3500–125–4500 (Gross Rs. 8080/-)
3. Post Doctoral Fellow	:	Consolidated Stipend Rs. 4000/- per month + Rs. 1000/- House Rent Subsidy.

Higher starting salary in the scale may be considered in exceptional cases.

Post nos. 1 and 2 are of regular nature and 3 is for one year tenure which may be extended for another term.

AGE LIMIT: 35 years in respect of Fellow/Scientist – SD and PDF. Relaxable by 5 years in case of SC/ST candidates.

The above norms are relaxable in highly exceptional cases. The Institute offers excellent career opportunities to creative, innovative and result-oriented staff. In addition to pay and allowances, perquisites like Contributory Provident Fund, Gratuity, Medical Facility under its Contributory Health Service Scheme, LTC, Group-Linked Insurance Scheme, Subsidised Transport and Canteen facilities are admissible as per Institute rules.

Out-station candidates called for interview will be paid first class to and fro rail/ordinary class bus fare by shortest route in respect of Associate Professor – I, Fellow/Scientist – SD and second class rail/ordinary class bus fare by shortest route in respect of PDF on production of proof of journey such as Railway/Bus ticket or ticket no.

How to Apply: Typed application on plain paper strictly in the following format with one recent passport size photograph duly affixed on it along with copies of marksheets, certificates, testimonials, etc. should reach Prof. P. I. John, Institute for Plasma Research at the above address [FAX: 91-079-7864310 E-MAIL: JOHN @ PLASMA.ERNET.IN] within 20 (twenty) days from the date of publication of this advertisement. **The envelope should be strictly superscribed with Advt. No. and Post Applied for.**

APPLICATION FORMAT

1. Advertisement No., 2. Post Applied for, 3. Name (in block letters), 4. Date of Birth, 5. Place of Birth, 6. Age, 7. Marital Status, 8. Present Address, 9. Permanent Address, 10. Whether belongs to SC/ST if so, attach documentary evidence, 11. Qualifications [SSC onwards, indicating (a) exam. passed, (b) board/university, (c) subjects, (d) year of passing, (e) division, (f) percentage of marks obtained], 12. Experience [indicating (a) name of the organization, (b) nature of work in detail, (c) period, (d) scale of pay and total salary drawn], 13. References, 14. Any other relevant information, 15. Signature with date.

Candidates employed in Govt./Quasi Govt./Public Sector undertakings should forward their applications through proper channel. The Institute reserves the right to reject any application without assigning any reason. **Applications not in the above format are liable to be rejected.** No interim correspondence will be entertained.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Investigating cosmic rays and gamma ray bursts

The present century has witnessed many revolutions in astronomical techniques. Gone are the days when all the information about the Universe used to be collected through a narrow band of the electromagnetic radiation spectrum, for which we are endowed with a natural detector—the human eye. First to appear outside this restricted channel was cosmic rays, discovered by Hesse in 1912, followed by radio and infrared, and then higher energy radiations with the opening up of the space window. In this issue we have two excellent articles reviewing two of such new techniques, giving first hand knowledge from their own scientific efforts.

'Cosmic rays', named by Millikan shortly after the discovery, is not a happy choice, as the pair of words conceal two misconceptions about the phenomena: These are not rays, but streams of very high energy particles, and we are still at a loss to understand their origin. To confound the issue further 'primary cosmic ray' particles are not directly detectable from ground being extensively modified by our atmospheric envelope. So, efforts were made over decades to hoist instruments up by balloons, rockets, satellites and space probes beyond our near space environment. In this direction the Indian collaborative effort 'Anuradha' has been a remarkable success; the story of its conception, design, fabrication and flight in a space shuttle has been described (**page 721**) by the leader of the project team, unfolding some glimpses of new findings of the nature of these particles.

The second topic covers the very high energy radiations from some cosmic sources; the article has been written by a team of scientists from ISRO who themselves have made considerable contributions. Gamma ray bursts were serendipitously discovered from some satellite experiments in late sixties; the observations had posed a puzzle, and ever since efforts towards unfolding their secrets are being pursued. The Indian scientific team has designed, fabricated new instruments and have them installed in two of their multi-purpose satellites. The article (**page 732**) describes the mystery surrounding the phenomena and suggests new efforts needed for understanding them.

Going beyond the Born–Oppenheimer description

One of the greatest challenges to chemical theory is the derivation of molecular level understanding of macroscopic properties. Two types of computational methods are currently employed for this purpose. First, single molecules or small clusters of them are studied using quantum chemical methods. Although the systems consist of interacting nuclei and electrons, a common approach is to treat the problem in stages. For a given frozen nuclear configuration, the electronic energy is computed. The process is repeated for different geometries to obtain a multi-dimensional potential energy surface. The problem of what the nuclei do in such a surface is solved subsequently. When a large collection of molecules is involved, Monte Carlo and Molecular Dynamics represent the best methods to use. The range of geometric configurations the system can adopt is generated by a Boltzmann sampling or by solving Newton's equation of motion. Of course, these calculations often use empirical potential functions and do not necessarily rely on PE surfaces derived from quantum chemical calculations.

An alternative computational strategy is becoming increasingly popular. It is to treat nuclear and electronic motions at the same time. The energetics of a system as it dynamically responds to changes in nuclear and electronic coordinates is evaluated using Quantum Monte Carlo methods. Technical details as well as computational nuances of these procedures are reviewed by C. Chakravarty (**page 739**). Some representative applications of the methods to interesting chemical problems are also discussed.

Fighting oxidative damage with vitamin C

Linus Pauling's enthusiastic espousal of the use of mega doses of vitamin C for staving off the common cold and cancer may not have found much favour in the scientific establishment. The Pauling campaign however promoted the widespread use of vitamin C and millions around the world probably have their own tales to tell of the benefits of regular consumption. The vitamin itself was first discovered accidentally, with the discoverer, Albert Szent-Györgi having no pretensions to belonging to the heroic tribe of vitamin hunters of the early decades of this century. Indeed, Szent-Györgi irreverently christened the white crystals, 'ignose' ('ig' for ignorance and 'ose' for sugar). Hexuronic acid and ascorbic acid were names that came later. While vitamin C was originally identified as the anti-scurvy factor its biochemical functions are diverse, stemming almost exclusively from its anti-oxidant properties. Oxidative processes are associated with many degenerative conditions and aging; unsurprisingly antioxidants are frequently touted as the universal panacea against a wide spectrum of physiological disorders.

In India, research on the biosynthesis of ascorbic acid was pioneered in the 1950s by B. C. Guha in Calcutta. This tradition has been well maintained in many of the researches on vitamin C that are described by I. B. Chatterjee and coworkers on **page 747**.

One Day Symposium on GENOME ANALYSIS: RECENT TRENDS AND APPLICATIONS

16 January, 1996

Invited speakers

A Bhattacharya	JNU, New Delhi
S K Brahmachari	I I Sc., Bangalore
G Padmanaban	I I Sc., Bangalore
J M Robertson	Applied Biosystems, USA
S K Sen	Bose Institute, Calcutta
E M Southern	Oxford University, UK

(Symposium will be concludeded by Panel Discussion on legal and ethical issues arising out of Human Genome Analysis)

Registration Fee Rs. 300/-

Last date of registration
31 December, 1995

Hands-on Training Course on DNA FINGERPRINTING

17 January - 4 February, 1996

* Course covers topics such as bacterial, human and population genetics, structure and sequencing of DNA, principles and applications of DNA fingerprinting, detection of genetic disorders by RFLP, fluorescence *in situ* hybridization (FISH), etc.

* Course also offers hands-on training in isolation of plasmid and bacterial DNA, vector-host systems, molecular cloning, *FISH*, DNA fingerprinting of samples of human/animal/plant origin.

Registration Fee Rs. 20,000/-
(inclusive of registration fee for symposium)

Last date for submission of application
30 November, 1995

Organized by

Centre for Cellular and Molecular Biology (CCMB), Hyderabad 500 007, INDIA

Sponsored by

Centre for DNA Fingerprinting and Diagnostics (CDFD), Hyderabad 500 007

Microbiology in India

Ramesh Maheswari's article on 'Whither microbiology? (*Curr. Sci.*, 1995, **69**, 401–406) should be an eye opener to all those microbiologists in India who think that salvation exists only in gene cloning and genetic engineering. We have not even seen a tenth of the microbial world and there is a lot more to explore and understand. What we have understood so far should form the basis of future biology, as Maheswari points out. The lopsided support that microbiology receives is one reason for believing that microbiology is not dead but is moribund. Neglect of classical microbiology is the reason why our national committee on plague has so far been unable to say what exactly caused the Surat epidemic. Carl Woese's thesis is only partly correct. Such ups and downs are seen in every branch of science. The reemergence of some of the well-known diseases is one instance where the Western world has realized the importance of classical microbiology. Let us not be discouraged by all that people in the West have to say. After all, all that comes from the West need not be the best. Undoubtedly, there is a need to reorient our teaching and research in microbiology if we are to meet the challenges of the 21st century. It is a pity that although this subject has been taught in more than 40 Indian universities under the UGC cover both at undergraduate and postgraduate levels, there is as yet no attempt made to evolve a standard undergraduate curriculum. There is no need to despair but there is certainly a need to evolve a new trend in teaching microbiology to include both classical and modern aspects.

Feast of the Gods?

Total solar eclipse – October 1995 (J. C. Bhattacharyya, *Curr. Sci.*, 1995, **69**, 486–488), will indeed be a spectacular event, which is bound to be fascinating for astrophysicists and equally for enthusiastic viewers. The mention of the comments of Dr M. K. V. Bappu, on the total solar eclipse of 1980, is full of aesthetic sense of feelings but the attempt to mix science with the feast of the Gods or for that matter with God even, sounds a strange contradiction.

Nobel Peace Prize for 1995 to Joseph Rotblat and the Pugwash Conferences on Science and World Affairs

The Norwegian Nobel Committee has awarded the Nobel Peace Prize for 1995, in two equal parts, to *Joseph Rotblat* and to the *Pugwash Conferences on Science and World Affairs*, for their efforts to diminish the part played by nuclear arms in international politics and in the longer run to eliminate such arms.

It is fifty years this year since the two atomic bombs were dropped on Hiroshima and Nagasaki, and forty years since the issuing of the Russell–Einstein Manifesto. The Manifesto laid the foundations for the Pugwash Conferences, which have maintained a high level of activity to this day. Joseph Rotblat was one of the eleven scientists behind the Manifesto, and has since been the most important figure in the Pugwash work.

The Conferences are based on the recognition of the responsibility of scientists for their inventions. They have underlined the catastrophic consequences of the use of the new weapons. They have brought together scientists and decision-makers to collaborate across political divides on constructive proposals for reducing the nuclear threat.

The Pugwash Conferences are founded in the desire to see all nuclear arms destroyed and, ultimately, in a vision of other solutions to international disputes than war. The Pugwash Conference in Hiroshima in July this year declared that we have the opportunity today of approaching those goals. It is the Committee's hope that the award of the Nobel Peace Prize for 1995 to Rotblat and to Pugwash will encourage world leaders to intensify their efforts to rid the world of nuclear weapons.

A note on the occurrence of columbite–tantalite bearing pegmatite at Limboi, District Sabarkantha, Gujarat

Although some rare earth and rare metal minerals like gadolinite ($Be_2 FeY_2 Si_2O_{10}$) associated with distinct large crystals of tin, from some tourmaline pegmatite of Palanpur–Hosainpur area[1] and pyrochlore ($Na_2CaNb_2O_6$) from carbonatite of Ambadongar area[2] are recorded in Gujarat, the presently reported columbite–tantalite (Fe, Mn) O (Nb, Ta)$_2O_5$ mineralization, which occurs as a discrete mineral phase in the granitic pegmatite in the Limboi area, district Sabarkantha, is first of its kind located in Gujarat.

Columbite–tantalite mineralization in the deluvial/eluvial pegmatite gravel around the quartz core, with a grade of 0.03–0.06% of the mineral by weight, has been established by preliminary test-pitting and panning at Limboi. Columbite–tantalite pieces vary from 5 to 50 mm across and a sample analysed by X-ray fluoroscence (XRF) has 60.07% Nb_2O_5, 15.35% Ta_2O_5, 1.29% Y_2O_3, 1559 ppm Sn, 0.30% Ce_2O_3 and less than 20 ppm Ba. Columbite–tantalite (confirmed by X-ray diffraction studies) is radioactive and has assayed 1.2% eU_3O_8, 0.2% U_3O_8 and 2.4% ThO_2, by conventional radiometric methods. Chemical analysis of another columbite–tantalite sample from the Limboi occurrence has shown 53.6% Nb_2O_5, 12.1% Ta_2O_5, 1.5% TiO_2, 2.71% Y_2O_3, 1.3% WO_3, less than 0.1% SnO_2 besides 0.288% U_3O_8 and 1100 ppm ThO_2. Other ore minerals that are present at Limboi include fersmite (Ca, Ce, Na) (Nb, Ta, Ti)$_2$ (O, OH, F)$_6$, fluorite and beryl.

The Limboi columbite–tantalite pegmatite, emplaced within the Idar granite pluton is an interior type of zoned granitic pegmatite which trends NNE–SSW and measures 350 × 200 m (Figure 1) and forms two distinct mounds. It comprises a prominent and highly fractured quartz core surrounded by an intergrowth zone consisting of quartz, K-feldspar, muscovite and tourmaline with columbite–tantalite, fersmite, fluorite and beryl. This zone is largely covered by soil and eluvial gravels. High yttrium content up to 2.71% Y_2O_3 in the columbite–tantalite samples from this pegmatite may suggest possible presence of xenotime, in the vicinity.

In view of a close cluster of pegmatites and massive quartz veins in the Idar–Verabar ghat section, the area in the neighbourhood of Limboi pegmatitic occurrence was further examined, to explore the possibilities of locating some more columbite–tantalite occurrences. This resulted in the location of three more pegmatite occurrences, viz. Sarangpur, Sabalwada and Bhavangadh (Figure 2). Columbite–tantalite samples from Sarangpur (23°51′47″N : 72°57′41″E, Toposheet No. 46A/13) have shown 51.80 to 52.89% Nb_2O_5, 21.07 to 21.37% Ta_2O_5 and 1.87 to 2.01% SnO_2.

The proterozoic rocks of the north Gujarat comprise mainly the metasedimentary sequences of the Aravalli and Delhi Supergroups with associated synkinematic as well as post kinematic, (Post Delhi), late Proterozoic granites. Post tectonic suites of intrusive granitic rock with dominant pegmatitic phases characteristically mark the close of igneous activity. The intrusion of granitoids during the period 950–700 Ma also resulted in widespread migmatization of the preexisting rocks in North Gujarat and SW Rajasthan, in the southern part of Aravalli–Delhi fold belt. Such younger phases of granitoids are known to yield residual fluids, which could be anomalously rich in rare metals and rare earths, depending upon the degree of fractionation. The trace element geochemistry and geochronology of the Idar granite[3] clearly correspond with the Erinpura granitic suite of rocks, dated 740 ± 10 Ma (ref. 4), occupying large tracts in the adjoining Banaskantha district (Gujarat) and Sirohi district (Rajasthan). These are highly differentiated granites and constitute younger fertile phases which might have contributed rare metals and rare earths to the mid-Proterozoic metasediments of Delhi Supergroup, in the contact zones and peripheral parts of the granite batholith.

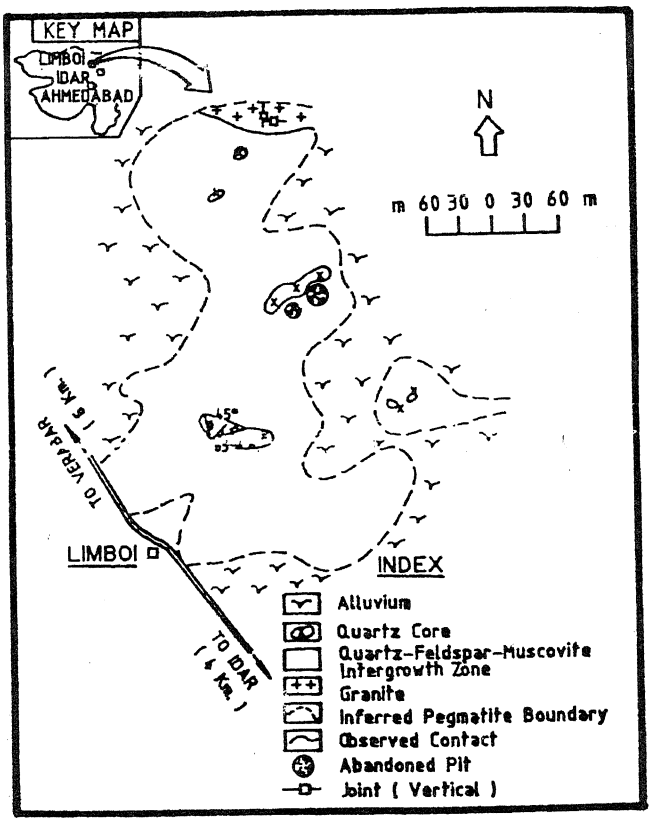

Figure 1. Geological map of Limboi pegmatite, Sabarkantha district, Gujarat.

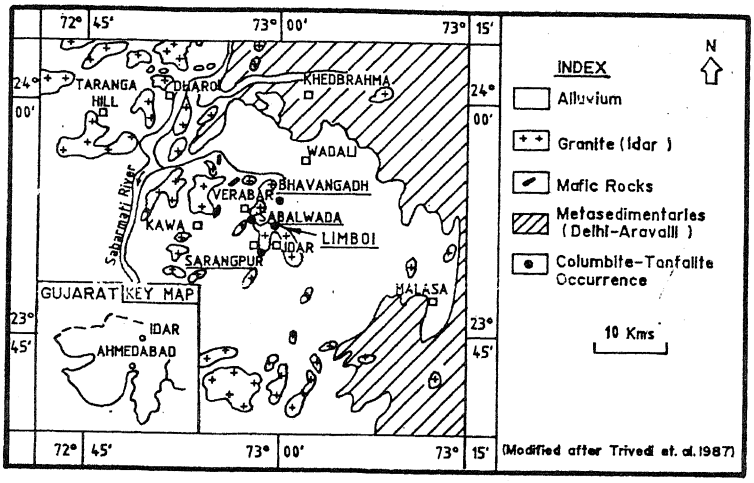

Figure 2. Geological map of Idar Area, North Gujarat, showing columbite–tantalite occurrences.

The presence of columbite–tantalite-bearing pegmatites around Limboi and granitic terrain occupying about 1200 km^2 have opened up vast area for exploration of rare metals and rare earths. Follow-up investigations in the area around Verabar, Kawa, Dharoi, Nadri, Nawawas, in the Sabarkantha district of Gujarat and also in the adjoining Banaskantha district of Gujarat and Sirohi district of southwestern Rajasthan are likely to be rewarding, as fertile granites are present in the area.

Discovery of the new radiation belt of the earth

Sukumar Biswas

The discovery of the new – the third-radiation belt of the earth has followed from the results obtained with the help of earth-orbiting satellites[1]. This discovery was made in three stages. The first evidence came in a striking manner in the Indian cosmic-ray experiment[2,3] in the SKYLAB-III mission of NASA during 1973–74. Further evidence was obtained from the results of the COSMOS satellites[4] of USSR flown in 1985–88. Finally, the confirmation and identification of the new belt was made from the results of the SAMPEX satellite[5] of NASA of USA in 1993.

Firstly, let us have a brief look at the two well-known radiation belts of the earth, the inner and outer belts discovered in 1958–59. These are also called Van Allen Belts after their discoverer, J. A. Van Allen of USA. A number of satellite experiments were needed to understand their properties and origin. The inner belt consists of energetic charged particles, mostly protons (of energy ~ 10 to 100 MeV) and some electrons which are confined in a dough-nut shaped volume around the earth by the earth's magnetic field. The charged particles travel in spiralling paths around the magnetic field lines and they oscillate between the north and south hemispheres. At the same time they circle around the earth, forming a belt-like structure. The centre of the inner belt is located at about 3,600 km altitude where intensity of fast protons is enormously high. Similarly, the outer belt, which is composed of mostly fast-moving electrons, extends from ~ 10,000 to 70,000 km altitude. It has extremely high intensity of fast electrons near its core at 20,000–30,000 km. These trapped radiation belts present serious radiation hazards to man and instruments in these regions of space.

A new kind of cosmic rays were first seen in interplanetary space in experiments on Pioneer 10 and 11 and IMP-8 spacecrafts of USA in 1973–74 (refs. 6–8). These new components of cosmic rays, called anomalous cosmic rays, were first seen in near-earth space, inside the earth's magnetic field in the Indian cosmic-ray experiment[2,3] on the Skylab-III mission of NASA. The surprising result found in this experiment was that the measured intensity in the solid state track detectors in Skylab was at least 25 times higher than the calculated value from the data in interplanetary space. How could it be possible?

It was proposed by the Indian group[3] that some of the anomalous cosmic-ray

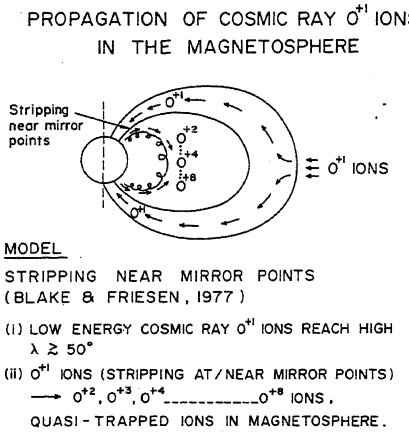

Figure 1. A sketch of the model of the origin of the newly-discovered radiation belt of the earth originating from the trapped anomalous cosmic ray particles, such as O^{1+} (from ref. 3). For details see text.

particles were trapped in the earth's magnetic field and these trapped or quasi-trapped particles were responsible for the excess flux. The mechanism for trapping was also suggested[3] by the Indian group. This mechanism, which is discussed a little later, is now accepted as the model for the origin of the trapped anomalous cosmic rays. In the Skylab experiment it was, however, not possible to locate the position of the new trapped component, for which more detailed experimentation was necessary.

A few attempts were made in early 1980s on this problem, but without success. In 1985–88, the USSR group made several COSMOS satellite flights with solid state track detectors, in some of which they noted double-peaked angular distributions of the oxygen ions of anomalous cosmic rays[4]. These were interpreted as arising due to the presence of a trapped component. Thus the evidence for the trapped component became stronger.

In 1992–94, the Caltech and NASA groups of USA flew a sophisticated mass spectrometer experiment in a NASA satellite, SAMPEX, whose orbit was at a higher altitude of 670 km. It was a polar-orbiting satellite with orbital inclination of 82° to the equator. The results from this experiment yielded the new evidence of the trapped anomalous cosmic rays[5], which confirmed earlier observations. It showed a distinct component which was due to trapped heavy ions of anomalous cosmic rays (ACR) and was composed mainly of oxygen ions of about 10–50 MeV/N. They located the new radiation belt of trapped ACR at a distance of about 6400 km above the equator. The trapped particles are confined in a torus-like region around the earth's equatorial region. From this volume a small fraction of trapped particles leaks out in high altitude regions of the upper atmosphere above the South Atlantic ocean region and these were detected by the earth-orbiting satellites when they passed through this region.

The mechanism for the formation of the trapped component of anomalous cosmic rays was proposed by the Indian group[3] and this is shown schematically in Figure 1, which is reproduced from the paper of Biswas and Durgaprasad[3]. In this model it is proposed that singly ionized ions of anomalous cosmic rays, such as O^{1+}, enter the geomagnetic field at high latitudes, say $\geq 50°$. Here a fraction of these suffer electron stripping process in the upper atmosphere near their mirror points according to Blake–Freisen mechanism[9]. The stripped ions having lower magnetic rigidities (i.e. momentum/effective charge) are trapped, forming the trapped component of anomalous cosmic rays. One may note that in this picture the ACR ions should be singly ionized; several experiments have determined that ACR ions of O, N, Ne are singly ionized[10]. The trapped heavy ions of ACR are stored in the belt for periods ranging from less than a day to about one year, depending on the ionization loss in the thin rarified regions of space where gas densities range from about 10^3 to 10^6 atoms/cm^3.

One may ask about the scientific usefulness or otherwise of this new radiation belt. The new belt is of weak intensity and so does not present any additional radiation hazard compared to the high intensity Van Allen belts. This belt, however, provides a new advantage. It is now established that ACR particles originate from neutral atoms of nearby interstellar space[10]; therefore the new belt of trapped ACR particles brings to us a sample of interstellar matter in near-earth space. Thus new properties of interstellar neutral matter, e.g. their isotopic composition, can be studied and new, important astrophysical knowledge may be obtained.

Gateways to the galaxy: New findings in cosmic rays from Spacelab-3 experiment 'Anuradha'

Sukumar Biswas and Jitendra Nath Goswami

The Anuradha cosmic-ray experiment, flown on board Space Shuttle Spacelab-3, remains one of the most successful Indian space science experiments conducted so far. This experiment provided the first direct and unambiguous results on the ionization states of the newly discovered anomalous cosmic rays that conclusively established the interstellar neutral atoms as their source. New and unexpected results on the properties and composition of low-energy cosmic ray heavy nuclei were also obtained. The scientific and technical activities that made this experiment a reality—from the planning stage to its operation during the Spacelab-3 mission, and the details of the post-flight data analysis and synthesis that provided the new results are described. Some new possibilities have emerged for future space experiments in this area.

Cosmic rays: A sample of galactic matter

LIKE many branches of science cosmic rays had a humble beginning. In the early part of this century, soon after the discovery of radioactivity, scientists were puzzled to note the leakage of electric charge from well-insulated bodies. To explore this problem, the German scientist H. Hess had flown well-insulated electroscopes in balloons in 1912, in one of which he himself was a passenger, and discovered that a penetrating radiation is impinging on the earth from extra-terrestrial sources. It was named cosmic rays by the American scientist R. A. Millikan, as the Sun could be ruled out as a source of this radiation. The energies of cosmic-ray particles are really astounding—it covers the vast span of about 10^6 eV to as high as 10^{20} eV. With instruments flown in high-altitude balloons it was discovered that cosmic-ray particles are composed of atomic nuclei of various elements such as hydrogen, helium, carbon, nitrogen, oxygen, etc. up to iron. In fact elements up to uranium are also present in cosmic rays with small intensities. The cosmic rays thus provide us with an unique sample of matter from interstellar space and opened to us a new window to the universe—to explore high-energy processes in the galaxy and beyond. On anticipating the fascinating discoveries in the field of cosmic rays, the eminent scientists, J. J. Thomson and J. P. Thomson remarked in 1928: 'It would be one of the romances of science if these obscure and prosaic minute leakages of electricity from well-insulated bodies would be the means by which the most fundamental problems in the evolution of the cosmos came to be investigated.' In the past decades many studies were made in spacecrafts to unravel the mysteries of the origin and acceleration of cosmic rays to high energies. In spite of spectacular progress, many of these problems still remain obscure and elusive. At present supernovae, their remnants, and pulsars are considered as likely sources of galactic cosmic rays; some of the radio-galaxies, quasars and active galactic nuclei could be possible sources of extragalactic cosmic rays. These studies have captured the fascination of numerous scientists in the world as high energy cosmic gateways to the galaxy and to the universe[1].

Sukumar Biswas is in the Tata Institute of Fundamental Research, Bombay 400 005, India, and Jitendra Nath Goswami is in the Physical Research Laboratory, Ahmedabad 380 009, India.

The discovery of anomalous cosmic rays

In the early 1970s, a new component of cosmic rays was discovered by analysing the data recorded in cosmic-ray detectors in Pioneer 10 and 11 spacecrafts that were on their way to Jupiter and in the interplanetary space probe IMP-8 orbiting the earth[2–4]. This component of low-energy cosmic rays of extra solar origin has some surprisingly new properties. In galactic cosmic rays, we normally have about 90% proton and ~ 9% of He, while C, N, O and heavier nuclei constitute ~ 1%. In contrast, in the new component of low-energy cosmic rays, protons were not detected, abundances of helium, oxygen, nitrogen and neon were enhanced, while other elements such as carbon, magnesium, silicon and iron had very low abundance or almost absent. As for

example, in the new component the abundance ratio of O/C is ≥ 5 in contrast to O/C ~ 1 in galactic cosmic rays (GCR). Because of its unusual composition and energy spectra, this new component of low-energy cosmic rays was called the Anomalous Cosmic Rays or ACR in short.

The ACR oxygen ions are the most well studied for their intensity and spectral characteristics in the energy range 4–50 MeV/n. The intensity of ACR oxygen and nitrogen ions decreases from ~ 5 to ~ 50 MeV/n, where it merges with galactic cosmic rays (see Figure 1). The ACR helium ions have intensities higher than the GCR component in the 10–100 MeV/n energy range. Another striking feature of the ACR that was revealed, as the two spacecrafts, Pioneer 10 and 11, travelled further away from the Sun, was that the intensity of the ACR oxygen ions increased continuously and near the orbit of Jupiter it was ~ 40 times higher than that near the earth. These data established that the Sun cannot be the source of the anomalous cosmic rays and they must originate from sources or processes located beyond the orbit of Jupiter. So what could be the origin of this new type of cosmic rays? Several new ideas were proposed in the seventies to explain the presence of the ACR component. Before discussing these, we shall have a quick look at the results obtained from another experiment conducted in 1973–74 using the Skylab spacecraft.

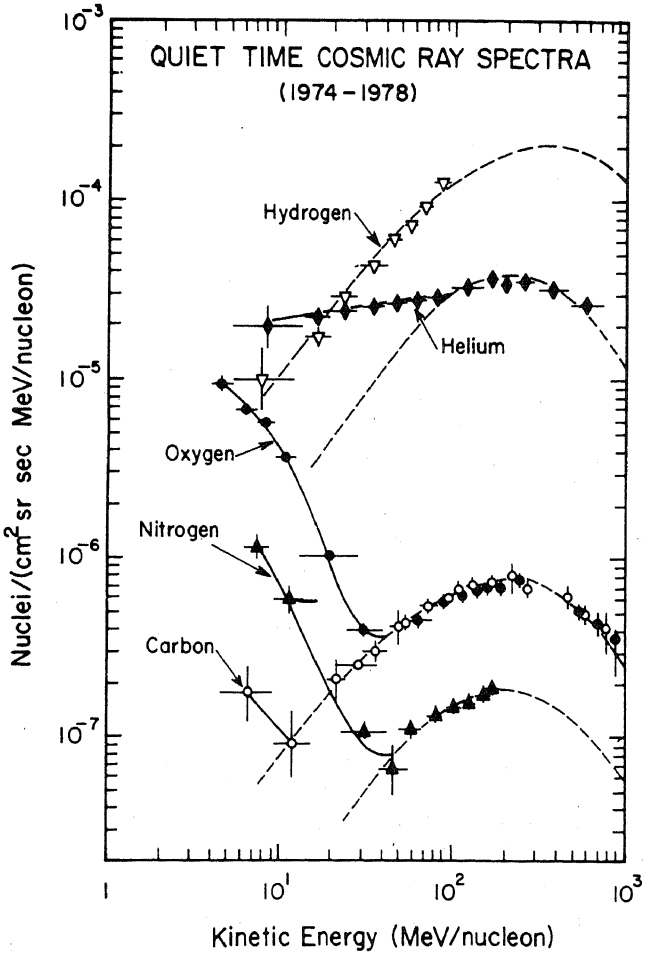

Figure 1. Energy spectra of H, He, C, N and O during solar quiet time of 1974–78. The solid lines indicate the ACR component; the dashed lines represent GCR component.

In the Skylab mission of NASA, a stack of passive solid state nuclear track detector (Lexan polycarbonate) was exposed on the outside of the Spacecraft for 74 days, between November 1973 and February 1974, a period that was entirely free from solar particle activity. Scientists from the Tata Institute of Fundamental Research (TIFR), Bombay, and the Physical Research Laboratory (PRL), Ahmedabad, have jointly analysed the data recorded in the detector stack and observed some strikingly new aspects of low-energy particles present within the earth's magnetosphere[5,6]. Firstly, ACR, O, N and C were observed for the first time inside the magnetosphere, with the same composition as in the interplanetary space. Secondly, it was concluded that these ACR particles must be in partially or singly ionized state; otherwise they will not be allowed by the earth's magnetic field to reach the Skylab orbit. Thirdly, the measured intensity of ACR oxygen was ~ 25 times higher than that expected on the basis of the measured interplanetary flux, from which it was concluded that ACR oxygen ions are trapped in the earth's magnetic field[6,7]. These findings made in 1975–80 have now been confirmed with instruments flown in different spacecrafts.

Where do anomalous cosmic rays come from? : Theoretical ideas

As the new data on the properties of the anomalous component of cosmic rays started accumulating, cosmic-ray theorists proposed a host of ideas to explain its origin. These ideas can be divided into two classes. The first category considers local galactic or solar system sources as responsible for generating the ACR component and predicts multiple charge states of ACR particles. McDonald *et al.*[2,8] suggested that the ACR particles originate in some unusual sources located in nearby interstellar space. Hoyle and Clayton[9] suggested that stars reaching white dwarf stage in stellar evolution may be responsible for the origin of ACR. Durgaprasad[10] proposed novae as possible sources, while Biswas *et al.*[11] suggested O-type stars emitting strong stellar wind as the ACR sources. A rather unusual model was proposed by Fowler *et al.*[12], who suggested that materials and gases brought in by comets are accelerated within the solar system to produce the ACR particles. All these theories would predict multiple charge states for the ACR particles, e.g. O^{1+}, O^{2+}, ... O^{8+}, etc. for ACR oxygen.

The other category of model, that considers local interstellar neutral atoms as the source of ACR, was proposed by Fisk *et al.*[13]. How do these neutral atoms evolve to become energetic anomalous cosmic-ray particles? A somewhat involved mechanism was proposed by the authors which constitute of four stages (Figure 2). In the first stage, interstellar neutral atoms enter the solar system as the Sun and the heliosphere (i.e. the volume in which solar plasma and magnetic field are confined) moves at a speed of 20 km/sec through the interstellar medium (ISM). The ionized particles in the ISM, on the other hand, are deflected at the heliospheric boundary by the solar magnetic field. This process therefore leads to the enhancement of those elements that exist predominantly in the neutral state of the ISM, i.e. helium, oxygen, nitrogen, and neon, and depletion of the elements that are mostly in ionized states, e.g. H, C, etc. In the second stage, when the interstellar neutral atoms approach the inner solar system, they are stripped off of their outermost electron by the strong solar UV radiation and they become *singly ionized* (i.e. He^{1+}, O^{1+}, N^{1+}, Ne^{1+}). This happens at different distances from the Sun, depending on the ionization potential of the element[14]. Once ionized, these particles are linked up with solar wind plasma and move outward with the speed of the solar wind, till they reach the boundary region of the heliosphere. The particles at this stage have an average energy typical of solar wind particles, i.e. 1 keV/n. In the third stage, these particles travel back and forth around the heliospheric shock front, which is the seat of random motion or turbulent magnetic field, and are accelerated from 1 keV/n to several hundred MeV/n. In the final stage, a fraction of the accelerated ACR ions diffuse back into the solar system where they suffer a decrease in their intensity and energy as they now move against the solar wind plasma in a situation similar to the case of transport of the more energetic galactic cosmic-ray particles. Thus we have singly ionized anomalous cosmic rays of ~ 1–100 MeV/n in the inner solar system. This model therefore predicts that ACR particles must be only in single ionized state, in contrast to the models of the first category which allows all ionization state of ACR. Thus, it was realized then that measurement of the ionization states of the anomalous cosmic-ray particles is crucial to pinpoint their source and origin. As this information was not available from experiments on board Pioneer 10/11 and IMP 8 spacecrafts there was a need for designing new experiments that could provide direct information on the ionization states of individual ACR particles. This brings us to the genesis of the Anuradha experiment.

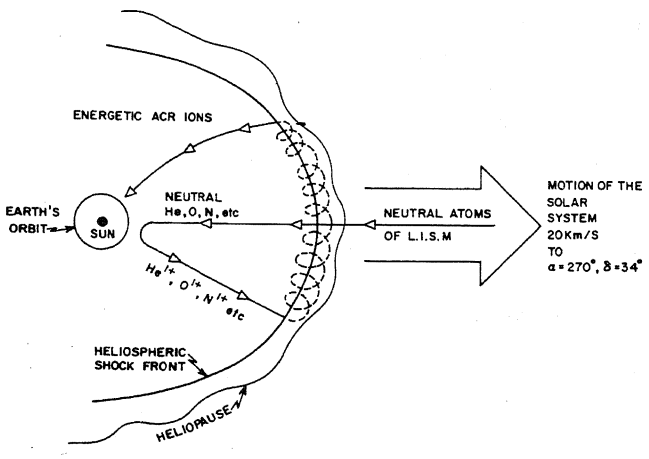

Figure 2. A schematic of the model proposed by Fisk *et al.*[13] to explain the origin of anomalous cosmic rays from interstellar neutral atoms.

Spacelab era begins: The 'Anuradha' cosmic-ray experiment

In 1977, the National Aeronautics and Space Administration (NASA) of USA invited proposals for new generation of scientific investigations from some of the major space research centres to be conducted in the Spacelab-1 mission aboard the Space Shuttle. The TIFR and PRL group of scientists, who were involved in the earlier Skylab experiment, jointly responded to the invitation and submitted a proposal entitled 'Studies of ionization states of solar and low energy galactic cosmic ray heavy nuclei', through the Indian Space Research Organization (ISRO). This proposal was selected by NASA for the Spacelab-1 mission, and this experiment, afterwards called 'Anuradha', was one of the two experiments from Asia, among about thirty US and European science experiments selected for this mission.

Scientific objective and instrument characteristics

The scientific objective of the Anuradha experiment was primarily to determine the ionization states of the newly discovered low-energy anomalous cosmic rays and also of solar energetic particles in case of solar energetic particle events occurring during the mission duration. The novel feature of this experiment was to use the earth's magnetic field as a giant spectrometer which filters out cosmic-ray particles according to their rigidity, i.e. momentum divided by effective charge (pc/Z^*). The instrument was designed in a manner that the arrival direction and time (and hence arrival location) of each of the cosmic-ray particle detected in the experiment could be determined. This information coupled with a model for the geomagnetic field allow us to trace back the probable complex trajectories of the incoming particles in the earth's magnetosphere and we can obtain

the minimum value of rigidity the particle must have to reach the Spacelab orbit at the point of its detection (see Figure 3). The other kinds of data obtained in the experiment are those recorded in the passive solid state nuclear track detectors which yielded the mass, nuclear charge, kinetic energy and momentum of each individual particles. Combining these results for each particle with its minimum permissible rigidity (R_{min}) obtained from the trajectory tracing calculation, the upper limit of ionic charge ($Z^* \leq pc/R_{min}$) of individual low energy anomalous and galactic cosmic-ray particles could be determined.

As the fluxes of the ACR particles are rather small, a large area detector of about 1200 cm^2 was used in this experiment. We used the newly discovered passive solid state nuclear track detectors with high sensitivity, called CR-39, and the detector films were assembled in the form of a circular stack composed of 150 sheets, each of thickness 250 μm and diameter about 40 cm.

A novel feature of the Anuradha experiment was its capability to determine the arrival time information of each cosmic-ray particles with an accuracy of ± 10 sec. This information and the record left by each particle in the detector, coupled with the information on the orientation and orbital parameters of the shuttle (which is available at all times) provide the arrival location (latitude, longitude and altitude) and direction of the particle as it entered the detector stack. To obtain the arrival time information, the detector module was divided into two stacks: a thin 'top' stack that was kept fixed and a thick rotatable 'bottom' stack that was coupled to a 15 bit absolute shaft encoder connected to a stepper-motor-gear assembly. The rotation of the bottom stack could be activated in steps of 40 sec of arc once in 10 sec so that it made a full rotation in 90 h. This part of the instrument was the most critical one, as very high mechanical precision in the fabrication and assembly is needed to achieve the high accuracy in the extremely small stepwise angular movement of a heavy load. The time information of an event in this detection arrangement can be obtained when an event is recorded both in the fixed 'top' and the rotating 'bottom' stacks of detectors. This is provided by the angular displacement between the two matched track segments produced by an individual event in the two detector stacks and the time history of stack rotation given by the shaft encoder output. Thus the information on the arrival time, location and direction of individual cosmic-ray particles is used for the trajectory computations and to obtain the value of R_{min} and finally its ionization states.

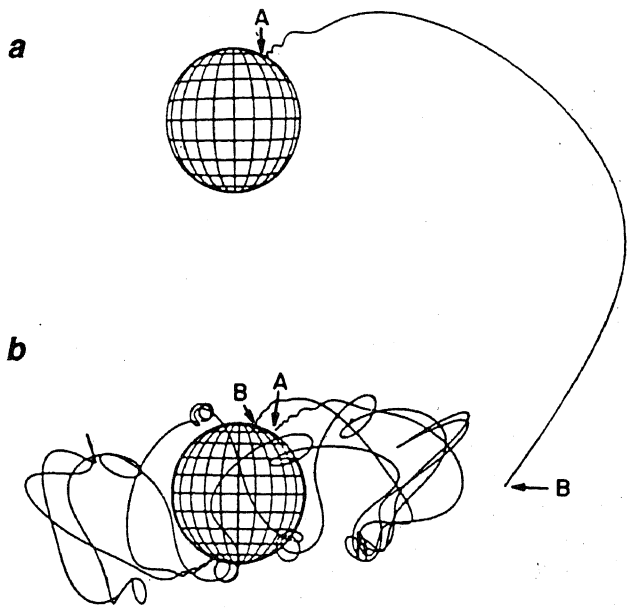

Figure 3. Complex trajectory of a cosmic-ray particle back-traced from its arrival point on Spacelab-3 orbit, for two values of rigidities: (*a*) shows an allowed trajectory that connects to the interplanetary space while (*b*) depicts the case when the assumed rigidity was too low for the particle to have an allowed trajectory.

One may ask the question why one needs the above complex procedures. The reason is that it is not possible to determine the ionization states of cosmic-ray particles by measurements confined in any detector system, active electronic or passive track detectors. This is so because when a cosmic-ray particle traverses a very small thickness of matter (~ a few μg/cm^2) in the upper most layer of a detector or its shielding, it is stripped off most of its orbital electrons and attain an equilibrium charge state and the information on the original ionization state is lost. Hence the momentum-filtering effect of the geomagnetic field is to be utilized, to obtain this information.

Anuradha takes shape

The detailed studies of experiment designs and requirements made in 1978–79 led NASA to work out a new schedule in 1980 for the Spacelab missions. It was arranged that Anuradha and another US experiment would be accommodated in Spacelab-3 mission in 1984–85, instead of in Spacelab-1. This rescheduling was most welcome as the orientation of Spacelab-3 was such that it provided continuous viewing of the deep space which was not the case of Spacelab-1.

A memorandum of understanding was signed by ISRO on behalf of the Govt of India and NASA in June 1980, according to which the Indian side had the responsibilities of the design, fabrication, assembling and testing of the instrument to meet the NASA specifications. NASA undertook its integration, flight operations, ground operations and related matters. The instrument and the data were to be returned to the Indian team for post-flight analysis.

The years 1980–82 were periods of intense activities on the design, procurement of materials and components, fabrication of mechanical, electrical and electronic systems and their integration, followed by various testings according to the NASA specifications. These were successfully accomplished by the engineering and scientific team members of TIFR–PRL–ISRO supported by BARC and several other centres. Six subgroups carried out specific works related to different subsystems. For example, the Detector Module Group of TIFR and the Laser Group of BARC had set up a special arrangement of CO_2 laser and He–Ne laser to cut ~ 500 CR-39 detector sheets—which are glass-like and brittle—into annular shapes of required dimensions. About 150 sheets of these were assembled in stainless steel housing and three such units were constructed.

The top enclosure—a curved sheet of Al alloy of thickness ~ 100 μm—was a critical element of the instrument as it must be thin enough to allow low energy (~ 8 MeV/n oxygen nuclei) to enter the detector and at the same time thick enough to provide an air-tight enclosure. Two pairs of venting valves maintained the inside pressure of the instrument at 0.1 atm during the flight and at 1 atm at all other times. The electrical and electronic systems and necessary softwares were fabricated and tested by the PRL group. This subsystem provided the required pulses to the high resolution stepper motor, which rotated the bottom stack by an increment of 40 sec of arc once in 10 sec (or by any other predetermined rate) and has the capability to correct for any overshoot or undershoot in the step movements. The rotational motion was read out by the 15 bit absolute encoder which was displayed and was monitored along with house keeping data such as the inside temperature of the instrument. Details of the instrument design and operation are given elsewhere[15] and a summary of the main characteristics is given in Table 1. A sectional view of the Anuradha instrument is shown in Figure 4.

Various tests of the instrument were carried out according to the NASA requirements at different Indian centres. The random and sinusoidal vibration tests, the thermovacuum and electromagnetic tests were carried out at the ISRO Satellite Centre, Bangalore. The acceleration tests were performed at the ISRO Shriharikota Centre and acoustic tests were done at IIT, Madras.

Four units of the Anuradha instrument were constructed—the engineering model for design testing, prototype model for all tests qualifications, the flight instrument for actual flight and the flight standby for contingency. After NASA's acceptance of test records, the flight instrument and the flight standby—installed

Table 1. Summary of Anuradha instrument features and flight characteristics

Weight	:	50 kg
Volume	:	48 cm diameter; 56 cm height
Detector	:	Composite CR-39 detector modules coupled to a high resolution stepper motor and a 15-bit absolute optical shaft encoder for arrival time and direction measurements of cosmic ray ions
Spacelab flight	:	Space shuttle Challenger launch – 29 April 1985; 1602 h GMT, and landing 6 May 1985; 1611 h GMT
Orbit	:	Altitude : 352 km Inclination : 57° to the equator Attitude : Gravity gradient stabilization
Ions exposure	:	Instrument activation, 123-12-44 GMT and deactivation, 126-05-00 GMT
Power allocation	:	10 W average for 90 h
Thermal control	:	Cold plate in pallet and a multilayer insulation
Command and data management	:	5 discrete on-off command channels 16 discrete data acquisition channels 1 analogue data channel
Experiment control	:	By stored program in on-board computer of SL-3 through I/O unit and interfacing with remote acquisition unit (RAU)
Data acquisition	:	CDMS telemetry of 372 bits every 1 s via TDRS and other satellites to ground station for stack movement and other house keeping data. Other data are recorded in track detectors and are processed post-flight.

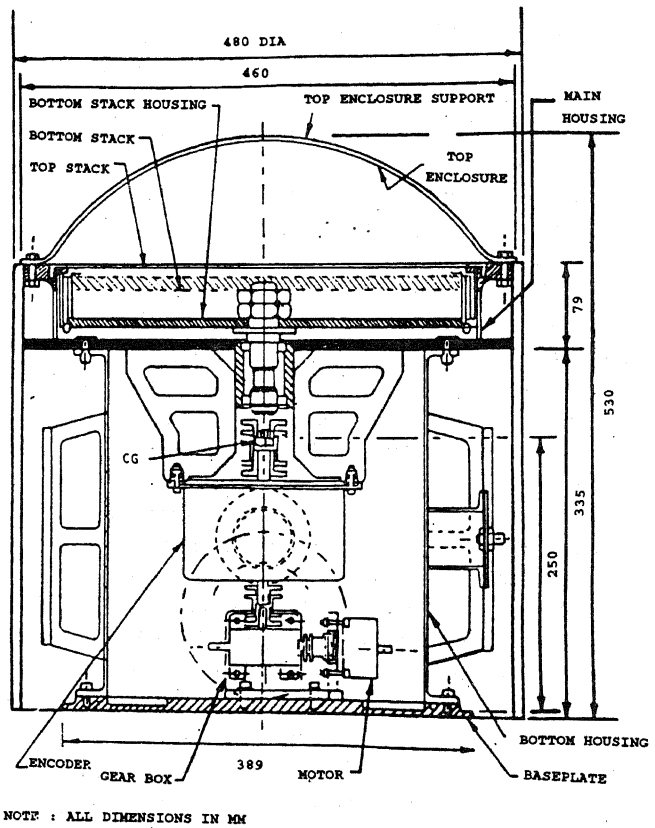

Figure 4. A sectional view of the 'Anuradha' cosmic-ray instrument.

specially designed containers and other accessories—were airlifted from India to NASA Kennedy Space Center, Florida, USA in December 1983. During 1984, NASA and Indian engineers installed Anuradha in the Spacelab-3 on the instrument-support structure and integrated it with Spacelab-3 electrical, electronic software and thermal control systems. In addition to passive thermal control with multilayer insulation, Anuradha was provided with active thermal control through a cold plate with circulating freon, on which the instrument was mounted. After the completion of various tests of the integrated payload, Spacelab-3 aboard Space Shuttle Challenger was ready for spaceflight in December 1984.

Space shuttle in orbit: Anuradha collects cosmic data

On mid-day of 29 April 1985, the space shuttle Challenger with Spacelab-3 on board was launched successfully into a circular orbit at a height of 350 km at an orbital inclination of 50° to the equator. The thirteen experiments flown in Spacelab-3 were in the areas of material science, life science, fluid mechanics, atmospheric science and astrophysics; countrywise, ten of these belonged to USA, two to France and one to India. A special feature of the SL-3 mission was the role of crew members, seven in number, five of whom were specially trained for the science experiments. A vax computer provided on-board support for control and operation of the experiments. These and other facilities in the mission enabled the scientists to undertake several new types of experiments for the first time. The Anuradha experiment could be activated and controlled either by SL-3 computer by a crew member or by ground commands from the control centre at Houston, Johnson Space Centre (JSC). Data were transmitted from Spacelab-3 by relay satellites to JSC Houston and Goodard Space Flight Center, Maryland.

When the Anuradha experiment was activated on the third day of the mission according to schedule it was found that some command channels were not responding while some others were operating. After studying the instrument response the Indian team informed the mission manager that the instrument characteristics are alright and the problem must be somewhere else, which should be identified and rectified. After a series of tests conducted by the NASA ground engineers and SL-3 crew, the problem was identified in the faulty NASA cable connecting SL-3 computer to the Anuradha experiment. As there was no spare cable, this problem was ingeniously solved by NASA engineers by replacing the faulty cable by a cable of another experiment, which just completed its operation. These and associated activities were carried out during a 24 h period and the instrument was switched on again on 3 May 1985. It was an exciting and dramatic moment for all present at the control centre to see that all channels of Anuradha were responding beautifully and the instrument operated perfectly for the next three days. It was switched off at the experiment closing time of the mission on 5 May 1985. A few photographs of the Anuradha and SL-3 mission are shown in Figure 5.

A schematic diagram of the experiment operation in orbit and of the flow of signals between Anuradha instrument in Spacelab-3 and the ground control centre is shown in Figure 6. The instrument operation takes place in the following manner. Once every 10 sec command signal generated by the experiment computer rotates the 'bottom' detector stack by one step of 40 arcsec and the encoder output is read out. The encoder reading, together with GMT, instrument temperature and other relevant information are transmitted from the SL-3 by high-rate multiplexer to payload operation and control centre once in 2 sec. The stepwise rotation is repeated once in every 10 sec, until a maximum of 32,736 rotational steps are made during about four-day period. In actual operation, Anuradha experiment had undergone rotational steps for about 64 h, i.e. for ~ 70% of the maximum value. The telemetered data of the instrument and of the Spacecraft position and orientation, were both recorded every 2 sec in the data tapes at the control centre and these tapes containing about 400 million data bits were provided to us by NASA for postflight analysis.

Postflight activities, data acquisition and synthesis

The postflight operations included the calibration of CR-39 stacks with three types of accelerator beams. Firstly, 50 MeV alpha particle beams from the Variable Energy Cyclotron (VEC), Calcutta were used to provide visible markings of the starting position of rotation on both the stacks. Secondly, 1 GeV/n ^{179}Au beams from the Bevalac, University of California at Berkeley, were used in vertically incident manner at six positions of the bottom stack to facilitate realignment of the CR-39 sheets after disassembly and processing. Thirdly, 140 MeV/n ^{56}Fe beams incident at 45° were used in six positions in the bottom stack to provide known events for charge calibration of the CR-39 detector.

Energetic cosmic ray nuclei incident on solid state track detectors such as CR-39 cause radiation damage along their path by breaking the chemical bonds of the constituent molecules. This leads to the formation of nascent damage trails of diameter ~ 100 Å which are preserved as latent tracks. When CR-39 detector sheets are treated with strong alkaline solution (e.g. 6.25 N NaOH at 70°C for 6 h) preferential etching takes place along the latent damage trails, which are revealed as conical etched tracks visible in an optical microscope.

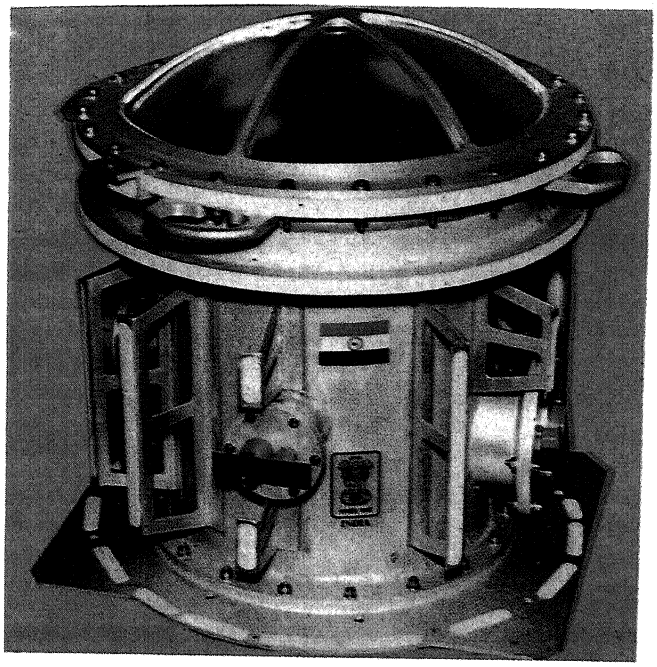

Figure 5 *a*. The Anuradha instrument.

The length of the etched cones, which is a measure of the ionization loss rate, and the residual range can yield the nuclear charge and kinetic energy of the incident particle[16,17]. Etched cones of a cosmic ray Fe nucleus traversing several CR-39 sheets are shown in Figure 7. In Anuradha experiment we initially scanned an annular area of width 2 cm in the two uppermost CR-39 sheets using a specially constructed semi-automatic microscope whose stage could be rotated in angular steps of 40 arcsec and in radial direction, R. The selected tracks of cosmic-ray particles, located in R, θ coordinate system, were followed through successive plates in the stack till the end of their range. A detailed analysis of track parameters was made which yields the atomic number, kinetic energy and other particulars of the incident cosmic-ray particles. Thus cosmic-ray ions of nitrogen to nickel of 8 to 150 MeV/n were identified.

The procedure of determining the arrival time and direction of the particles involves more complex procedures as briefly described earlier. By matching track segments in the top (fixed) stack and in the bottom (rotating) stack using algorithm that uses four or more track parameters, angular displacement between the track segments is obtained. This information when combined

with the telemetered data on encoder position vs GMT and orbital parameters of SL-3 yielded the arrival time and direction of the cosmic-ray particle.

Complete details of these procedures are given by Singh[18] and Dutta[19]. A total of about 100 cosmic-ray particles of carbon to nickel in the energy range ~ 12 to 150 MeV/n were identified and all the relevant data obtained in each case. For the trajectory tracing calculations we have followed the approach of Shea and Smart[20] and used a polynomial expansion of 10th order and the parameters suggested by the International Geomagnetic Reference Field (IGRF) for the epoch 1985 for an accurate representation of the geomagnetic field. The effects of external current system etc. were also considered in the final analysis of the data.

Anuradha results: New findings in anomalous and galactic cosmic rays

The scientific results from the Anuradha experiment had several new features and we shall briefly discuss these and their implications.

Firstly, the Anuradha experiment established the detailed method of using the earth's magnetic field as a giant momentum analyser for the accurate determination of minimum rigidities of individual cosmic-ray particles utilizing the arrival time and direction information[21,22].

Secondly, the mean ionization state of a sample of ACR oxygen ions was determined as O^{+1} for the first time using the orbit averaged flux method[23,24]. In this method data for the interplanetary ACR flux obtained by spacecrafts are used to calculate the expected flux of ACR oxygen inside the magnetosphere for different assumed ionization states. These values were then compared with the measured orbit averaged fluxes in Anuradha to determine the charge state of ACR oxygen as 1^+ (Figure 8). Recent studies by a Russian–US group of scientists, who used this method and analysed data from COSMOS and IMP-8 satellites, have confirmed this result[25].

Thirdly, the ionization states of 75 individual low-energy GCR and ACR particles were successfully measured for the first time[21,26]. Sixteen of these events were identified as ACR particles of N, O and Ne, whose upper limit of ionization states show that they are singly ionized or consistent with it[21,26] (Figure 9). The distributions in geographic latitude and longitudes of these ACR particles were found to be uniform (Figure 10) as expected and so also their arrival times.

Fourthly, a new unexpected result was obtained while measuring the ionization states of low-energy heavy ions. It was found that galactic cosmic-ray ions of sub-iron (Sc to Cr) and iron (Fe–Ne) group of 30–150 MeV/n are composed of about 20% particles which are partially ionized, e.g. Ti^{6+}, Cr^{5+}, Fe^{10+}, etc.[22,26]. This is contrary to the normal assumption that all GCR particles are fully ionized.

Lastly, another significant observation is that the abundance ratio of sub-iron to iron group of particles in low-energy GCR (30-130 MeV/n) within the magnetosphere is about a factor of two higher than the interplanetary value[27]. This, we believe is due to the presence of partially ionized ions in GCR at these energies.

Implications of the new findings, gateways to the galaxy and future perspective

The results from the Anuradha experiment established that ACR particles originate from interstellar neutral atoms and these are in singly ionized state as proposed by Fisk *et al.*[13]. However, details of the acceleration mechanism are yet to be fully understood[28]. It is gratifying to note that recent satellite experiments of German–US collaboration[29] and Caltech–NASA groups[30] have adopted the basic method of the Anuradha experiment and have confirmed our results on the ionization states of ACR particles.

The ACR particles bring to us a new sample of interstellar matter undergoing ionization and acceleration. One can attempt to deconvolute the processes to estimate the abundances of neutral atoms in ISM as discussed elsewhere[28]. Also, one can determine the isotopic composition of neutral atoms in ISM from ACR particles, as these remain unaffected by the intervening processes. A recent satellite experiment has also identified the presence of a third radiation belt composed of trapped ACR particles in near earth space[30]. This confirmed our observations made in the Skylab experiment in 1973–74 (see review by Biswas[31]). Now we can have easy access to a large flux of interstellar particles in the near-earth space.

Energetic particles of galactic cosmic rays (GCR) have travelled a significant amount of matter (~ 10 g cm^{-2}) in interstellar medium before reaching us. Hence these are mostly bare nuclei, stripped of their orbital electrons. The known values of electron capture and

stripping cross-sections measured in the laboratory show that iron group nuclei in GCR can capture orbital electrons only at very low energies (1–5 MeV/n) and above 10 MeV/n, electron stripping dominates. Therefore, the important question arises, how do we get GCR iron and sub-iron ions of ~ 100 MeV/n in partially ionized states observed in Anuradha? Logical conclusion appears to be that these particles captured electrons at low energies and are subsequently accelerated to > 100 MeV/n in ISM and have traversed very small amount of matter before reaching the solar system. Thus, our observation provides evidence for reacceleration or distributed acceleration of GCR in ISM. Probable sites for reacceleration are shock fronts of supernova remnants in ISM. Confirmation of the above will have important new implications on acceleration of galactic cosmic rays. Several attempts are currently on to study this enigmatic component of cosmic rays (e.g. see ref. 32).

Future space experiments may explore these new pathways to interstellar medium using low energy anomalous and galactic cosmic rays as tracers. Measurements of ACR oxygen flux beyond the orbit of Uranus during the period of minimum solar activity in 1997–98 will give definitive results on the intensities of these particles at the boundary region of the heliosphere and hence their energy density in the local ISM. In galactic cosmic rays, the new phenomena of partially ionized low energy iron and sub-iron group of particles need further studies. Such experiments should hopefully allow us to build new gateways to explore processes taking place in local interstellar medium as well as further away within our galaxy.

Summary

Studies of energetic cosmic-ray particles, that are an unique sample of matter from the interstellar space, continue to provide us with new insights of the high energy nuclear and astrophysical processes taking place within our galaxy and beyond. A significant recent contribution in this context has been the findings of the extremely successful Indian cosmic-ray experiment 'Anuradha' flown on board space shuttle Spacelab-3. This experiment was planned and executed jointly by scientists from the Tata Institute of Fundamental Research, Bombay and Physical Research Laboratory, Ahmedabad, under the aegis of the Indian Space Research Organization (ISRO), and with active help and collaboration from various ISRO centres and the Bhabha Atomic Research Centre, Bombay. The main scientific objective of the experiment was to determine the ionization states of the newly discovered anomalous cosmic rays to identify their source and origin. A very special experimental payload, that combines a passive nuclear particle detector and an active electro-mechanical system,

was designed and constructed to achieve this objective. Some of the important results obtained in this experiment are: (i) a clear demonstration that the geomagnetic field can be used as a giant momentum analyser for determining the rigidity (momentum/charge) of individual low energy cosmic-ray particles impinging on the earth, (ii) the first direct determination of the ionization states of individual anomalous cosmic-ray particles, which showed them to be singly ionized and confirmed the interstellar neutral atoms as their source, and (iii) detection of low energy partially ionized iron group particles in galactic cosmic rays, a completely unexpected result with important significance. The basic principle used in the Anuradha experiment has been adopted in a couple of recent satellite experiments that have confirmed the results on the ionization states of the anomalous cosmic rays obtained in the Anuradha experiment. Further studies of the enigmatic partially ionized iron group particles are also being pursued in these experiments. The findings of the Anuradha experiment point towards the exciting possibility of understanding the elemental and isotopic composition of the local interstellar matter by sampling the anomalous cosmic rays in the interplanetary or the near-earth space.

Cosmic gamma ray bursts – Recent developments and observations from SROSS satellites

K. Kasturirangan, V. N. Padmini, N. L. Prasad and U. R. Rao

ISRO Satellite Centre, Airport Road, Vimanapura P.O., Bangalore 560 017, India

Amongst a dozen energetic phenomena discovered during the past quarter century, the enigma of classical gamma ray bursts (GRBs) is as great as ever, with no consensus on what causes these bursts. The once dominant galactic neutron star model of GRBs has lost its popularity to the extragalactic and cosmological models in view of COMPTON's observations. The observational efforts in tracking down these mysterious sources are at the moment truly international, with emphasis on the best localizations followed by deep searches for counterparts at other wavelengths.

COSMIC gamma ray bursts (GRBs), first reported by Klebesadel *et al.*[1], continue to remain as one of the long-standing puzzles in high energy astrophysics, after twenty-five years of their discovery. GRBs are transient, non-terrestrial phenomena occurring randomly in space and time, lasting a few ms to a few minutes and characterized by bursts of intense radiation, predominantly at gamma ray wavelengths with bulk of their emission > 100 keV. The US Vela satellites that were launched to monitor any violations of the 1963 nuclear test ban treaty, recorded these events on their gamma ray detectors as early as 1967, but the announcement of this discovery of a new class of astrophysical phenomena had to wait until 1973, when the US military allowed the information to be made public.

During the period from 1973 to 1991, over 500 bursts with fluence $>10^{-6}$ ergs/cm^2 have been recorded by instruments mostly scintillation spectrometers flown onboard at least 20 satellites, viz. Vela, Helios 2, HEAO 1 & 2, Prognoz, ISEE-3, Solar max mission, Ginga, Apollo, etc. and inter-planetary probes like Venera 11, 12, 13, 14, Pioneer Venus orbiter, Phobos, etc. Studies on GRBs have proved difficult due to their transitory nature. The most general methodology of GRB study involves temporal and spectral studies, spatial distribution of an ensemble of bursts and other wavelength observations. Data collected on GRBs usually consist of a record of intensity variations as a function of time, over a wide energy band (Temporal profile) and energy spectra recorded at constant time intervals.

Over the years, two classes of GRBs have been recognized[2], viz. Classical GRBs, which account for the majority of bursts observed and Soft Gamma Repeaters (SGRs), three of which are known. The relation between the two, if any, is not clear. Time profiles of classical GRBs display a wide variety of shapes and durations varying from few seconds to a hundred seconds, with hard spectra (peak power at energies > 100 keV) which evolve with time. Typical rise and decay times range from 0.1 to 1 s. Classical GRBs are not known to repeat. SGRs, have nominal durations of 0.1–1 s, exhibit soft spectra with e-folding energy ~ 30 keV, which are time invariant. SGRs repeat at irregular intervals.

Although about a hundred models have been proposed to explain the origin of gamma ray bursts, none has so far been able to explain all the observations satisfactorily. The mystery shrouding soft gamma repeaters has been of late, largely resolved by multiwavelength counterpart observations. In contrast, classical GRBs have so far not been identified with any known population of objects in the universe, despite conducting deep searches to identify their counterparts at other wavelengths. As the distance to the source is as yet unknown, the total energy involved in the burst process has remained ambiguous by about 23 orders of magnitude.

With the launch of NASA's Compton Gamma Ray Observatory (CGRO) in April 1991, which carries onboard an instrument to monitor GRBs with unprecedented sensitivity, viz. the Burst and Transient Source Experiment (BATSE)[3], there has been a significant change in the quality of data and also the interpretation of the results. BATSE with its sensitivity to bursts with fluence $>5\times10^{-8}$ ergs/cm^2, which is an order of magnitude superior to its predecessors, records about one burst per day and has accumulated data on about 1296 bursts till 8 June 1995 (ref. 4). Prior to Compton, there existed a wide consensus that gamma ray bursts originate due to some catastrophic event on or near the surface of a neutron star in our galaxy. The discovery by BATSE that bursters have an isotropic, but radially inhomogenous distribution in space has altered the thinking of many theorists. As CGRO observations favour a distribution greater than at least 50 kpc, the mystery on the origin of GRBs has only deepened further and at the moment it is unclear whether these are of galactic or extragalactic origin. Recent reviews on GRBs, by Hurley[5], Higdon

and Lingenfelter[6] and conference proceedings edited by Fishman *et al.*[7], provide abundant information on observations, analysis and models of GRBs.

In the following sections, we review GRBs, from an observational point of view, as they were understood prior to the launch of CGRO and the highlights of results following the launch. The motivation for the Indian GRB experiments flown on the Stretched Rohini Satellite Series (SROSS-C, May 1992; SROSS-C2, May 1994) and their observations are also presented. Also discussed is the possible contribution of SROSS-C2 to the third interplanetary network of detectors currently monitoring GRBs.

Pre-CGRO era

Prior to the launch of CGRO, there existed a wide consensus that a GRB is caused by some catastrophic event near the surface of a neutron star in our galaxy. The observations suggested that most of the common classical burst sources are single, intensely magnetic neutron stars in the nearby galactic disk, and that the SGRs could be neutron stars with slightly weaker magnetic fields and possible binary companions. The circumstantial evidence which led to the galactic neutron star hypothesis was:

i) Very small source size < 1000 km, implied by rapid time variability in classical GRBs and < 60 km implied by the 0.2 ms rise time of GB790305b (ref. 8).
ii) Location of GB790305b event within the N49 supernova remnant (SNR) in the Large Magellanic Cloud (LMC) (ref. 8).
iii) Very high mean density > 10^6 g/cc implied as minimum density against breakup, if the 8 s period in the soft repeater GB790305b is rotational[9–11].
iv) Absorption lines between 20 and 70 keV in about 15% of classical bursts, which are attributed to cyclotron absorption in Terragauss magnetic fields[12,13]. These were further confirmed by the Japanese satellite Ginga[14] which observed bursts with two lines harmonically spaced, viz. at 20 & 40 keV.
v) Emission lines seen between 350 and 500 keV in both classes of bursts[12,13] – interpreted as gravitationally redshifted electron position annihilation radiation with neutron star redshifts of 0.1 or more[15].
vi) Failure to detect quiescent counterparts at other wavelengths within the source positional error boxes[16–22].
vii) Galactic distances implied by the black body limit derived from soft X-ray emission from GB870303 (ref. 14).

Further, the size-frequency distribution, which indirectly provides information on the radial distribution of sources, was found to follow the $-3/2$ power law for bright bursts, while the distribution deviated significantly for weak bursts with a flattening at lower fluences. This flattening at low fluence was considered as an evidence of a galactic origin, with more distant sources exhibiting nonuniform spatial distribution. The angular distribution of sources was however found to be isotropic, which is not consistent with a nonuniform spatial distribution if the burst sources are members of a galactic disk or halo population[23,24].

High sensitivity balloon observations[25,26] of bursts with fluence > 10^{-8} erg/cm^2 also suggested that the flattening of the size frequency distribution at low fluence was due to spatial nonuniformities and not due to selection biases. If true, the distribution of low fluence bursts would exhibit anisotropy with a concentration at low galactic latitudes. The BATSE experiment on CGRO was designed to resolve this contradiction.

The CGRO era

Compton's BATSE was designed specifically to investigate weak GRBs and localize them using its eight large 2000 cm^2 sodium iodide scintillation detectors mounted along the eight corners of the spacecraft providing an all-sky coverage. The events recorded are localized to an accuracy of a few degrees using the anisotropic response of the detectors. While this accuracy falls short of that needed to pinpoint visible counterparts, it suffices to map the burster distribution on the sky. In response to a trigger signal from BATSE, the other instruments on Compton[27], viz. Oriented Scintillation Spectroscopy Experiment (OSSE), the Compton Telescope (COMPTEL) and the Energetic Gamma Ray Experiment Telescope (EGRET) switch to a burst data collection mode, if the source occurs within their field of view. While COMPTEL can measure energy spectra of GRBs with high resolution between 0.1 and 10 MeV, it is also capable of localizing sources to about a degree. The EGRET instrument covers the broadest energy range from 20 MeV to 30 GeV. The Compton instruments have detected several unique individual events, the shortest event lasting ~ 100 μs (ref. 28), a few bright GRBs whose emission extends greater than 30 MeV (ref. 29) and two bursts from the region of SGR1900 + 14 (ref. 30). BATSE has also studied the spectra of the brighter bursts and searched for cyclotron line features[31–34]. Even though no definite evidence for lines is found, statistics do not yet support a clear inconsistency between BATSE and earlier mission results.

The most astounding result from BATSE data is that the angular distribution of GRB sources is found to be as isotropic as ever, with no concentration towards the galactic plane, or in directions of any other nearby galaxy or clusters of galaxies[35]. Figure 1 shows the spatial distribution in galactic coordinates of 1000 BATSE bursts[36]. BATSE has also detected fewer weak

bursts[36] (Figure 2) than would be expected for a $-3/2$ power law (shown by dotted lines), implying that the source distribution is not uniform out to infinity. In other words, weaker sources are fewer than expected, indicating thereby a boundedness to the region of source confinement. As burster models have to necessarily account for these important results on spatial and intensity distributions, these results have triggered a flurry of modelling activity, with a raging controversy on the burster distance scale.

Burster models and the distance debate

Prior to the launch of Compton, there existed a wide consensus on the local heliocentric models which favour the galactic neutron star paradigm. In these models the burster population is assumed at a distance of say 100–200 pc but still within the confines of the galactic disk in the solar neighbourhood. One of the early models

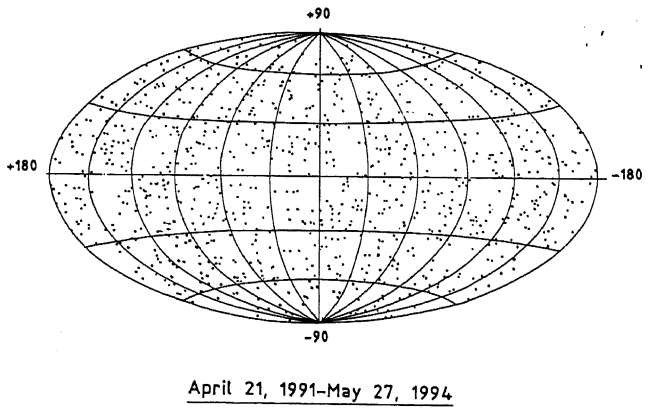

Figure 1. Spatial distribution of 1000 BATSE bursts.

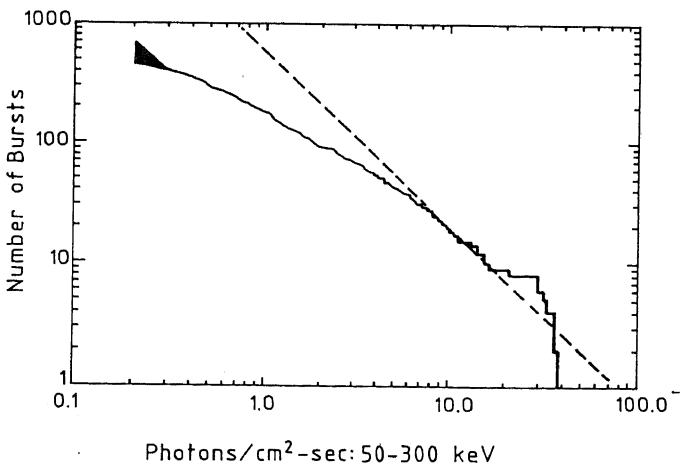

Figure 2. Integral peak flux distribution for 455 BATSE bursts.

focused attention on the retention of a cometary cloud by a collapsing star and subsequent fall/accretion of a solid object of mass $\sim 10^{17-19}$ g onto the neutron star releasing about 10^{36-40} ergs of energy in an explosion[37,38]. Another model, viz. the thermonuclear model, first proposed by Woosley and Taam[39], received more detailed attention over the years and predicts GRBs to occur due to slow accretion of matter from a companion or from the interstellar matter, leading eventually to a helium flash when the critical density and temperature are reached. Gamma radiation is believed to be produced due to magnetic reconnection. Though these models easily explain isotropy, a decrease in the density of sources far away is not expected, as the sun does not occupy a special place in the galaxy and there is no known population of galactic objects at these distances. Considering distances larger than the galaxy's thickness, we run into the opposite problem, i.e. while the radial inhomogeneity is easily explained, an anisotropy towards the galactic plane is not seen.

As of now, with the constraints imposed by BATSE observations on the spatial distribution of faint GRBs, the most widely accepted distance models place the GRB sources either in the outer regions of our galaxy (galactic corona models) or close to the event horizon of our universe (cosmological models). The former model postulates a source population extending about 100 kpc and centered on the galaxy such that the Sun's offset with respect to the galactic centre is negligible. While this galactic corona model explains both isotropy and radial inhomogeneity of burster distribution, the problem here is to populate a halo with neutron stars and find an explanation as to why they became active GRB sources in the halo and not when they were within the galaxy. Population II neutron stars, i.e. those formed by accretion-induced collapse of white dwarfs with birth velocities greater than 1000 km/s are believed to be shot out into the halo surrounding the galaxy[40]. Quakes on neutron stars, which produce about 10^{42} ergs of energy have been suggested as powering mechanisms[41]. As yet, there is no clear evidence supporting the existence of such a structure in the galaxy.

If the cosmological scenario is considered, isotropy follows very naturally, and the flattening of the size frequency distribution is attributed to the effects of the expansion of the Universe[42,43]. The most popular scenario for cosmological bursts involves a collision in a close binary consisting of a black hole and a neutron star or two neutron stars. The orbit of a binary neutron star, particularly those with tight orbits like binary pulsars, decays due to emission of gravitational radiation and eventually coalesces and merges releasing 5×10^{53} ergs mostly as a neutrino burst or as gravitational energy. For GRBs to be detectable at cosmological distances, only a fraction as small as 10^{-3} of this energy is required

to be converted to gamma rays. Such events are estimated to occur in the universe at a rate of 10^{-6} per year per galaxy which is comparable to the GRO burst detection rate. It also follows that other cosmological effects like time dilation, redshift and gravitational lensing should be observable in the weak bursts. Recently an announcement of time dilation in faint BATSE bursts by a factor of 2 has been adduced as evidence[44] for the cosmological distance scale.

At the moment, the mystery of gamma bursters has only deepened and is awaiting some observations or theoretical developments that would settle the dispute on the distance scale. Since neither the location of GRB sources nor their repetition rates are known, pre-planned observations in other wavebands are not feasible. Quiescent counterparts of bursters have been sought both in survey catalogues of unusual objects which might lie in any of the burst error boxes and in deep observations of the more precise error boxes in various wave bands. Since detectors more sensitive than the BATSE are unlikely to be built and flown for some more time to come, the only hope on resolving the GRB puzzle may be pinned down to observations of GRB counterparts at other wavelengths.

Search for counterparts

The success of any search for counterparts relies heavily on the ultimate size of the error box that can be achieved. GRBs being infrequent phenomena, require omnidirectional detectors, as accurate pointing from a single detector is not practicable. The location of the source is determined post facto either by using the angular dependence of several detectors[24,45] or by the triangulation technique[23] using the time difference in the arrival of the signal between two spacecrafts. While the single satellite method is capable of localizing sources with accuracies of only a few degrees, the latter method is necessary to reduce the size of the error box to several tens of arcmin or better so as to facilitate observations at other wavelengths.

The searches for counterparts of the SGRs have been too successful and it now appears certain that SGRs may be related to young magnetized neutron stars in supernova remnants. SGR0526-66, which emitted the historic burst of 5 March 1979, was detected by about ten spacecrafts and triangulation has yielded an association with the SNR N49 in the LMC. This source has burst sixteen times over the years and a faint X-ray source consistent in position with the GRB error box has been detected by ROSAT[46]. The other two repeaters, viz. SGR1806-20 and SGR1900 + 14, have been observed by CGRO to turn ON again[47]. SGR1806-20 has produced 100 bursts irregularly spaced in time between 1979 and 1985 and 6 bursts in 1993 (ref. 47). A galactic SNR G10.0 – 0.3 (ref. 48) and an X-ray source AX1805.7-2025 (ref. 49) have been associated with the SGR1806-20. Simultaneous X-ray and gamma ray bursts have also been observed by the Japanese ASCA satellite and CGRO[50]. SGR1900 + 14 has burst 6 times during 1979–1993 and is probably associated with the galactic SNR G42.8 + 0.6, although its location lies just outside the remnant[51]. At this time, as the nature of classical GRBS is not known, this provides a strong encouragement for counterpart searches as most GRB models require some counterparts to be detectable at some wavelength on some timescale.

Search for counterparts of classical GRBs during the quiescent states, inside GRB errorboxes, has been attempted in all wavebands[52], viz. soft X-ray, ultraviolet, optical, infrared and radio bands. About a dozen optical transient images of astrophysical origin found on archival plates[53] are reported, but their relation to GRBs is unclear. While flaring and fading phase (few hours to few days) searches have technologically limited the observations to X-ray, optical and radio wavebands, until recently searches on timescales shorter than a day were not possible. With BATSE and COMPTEL positions available within a few hours of the burst[54], and the response time of interplanetary networks being about one day[55], fading phase observations are expected to be more fruitful in the near future.

The Interplanetary Network (IPN)

The success of counterpart search depends on the best localizations possible with a network of interplanetary satellites, by the triangulation technique. At the present time, USA's Compton Gamma Ray Observatory and India's SROSS-C2 satellite in near earth orbits, Russia's GRANAT[56] in a highly eccentric orbit around the earth, the international Ulysses probe[57] in a solar polar orbit and the international WIND[58] spacecraft heading for placement at the first Lagrangian point of the Earth–Sun system carry instruments that form the third interplanetary network of GRB monitors.

The GRANAT spacecraft carries three experiments which can record gamma rays, viz. SIGMA – a coded mask telescope; PHEBUS – six Bismuth Germanate scintillation detectors (each 48 cm^2 area) for recording and localizing GRBs; and WATCH – a wide angle telescope. The PHEBUS experiment records bursts of the $> 10^{-6}$ ergs/cm^2 fluence class and the other two experiments compliment this data with their imaging capability. The WIND spacecraft carries two experiments which are capable of recording data on GRBs, viz. the Konus-W gamma ray spectrometer which has two identical sodium iodide detectors (120 cm^2 area) and the Germanium Transient gamma ray spectrometer (TGRS) which is meant for conducting high resolution spectral measure-

ments on GRBs with a sensitivity to fluence greater than a few times 10^{-7} ergs/cm^2.

The hard X-ray detectors on Ulysses consist of two hemispherical thallium-doped caesium iodide shells (40 cm^2 area) each coupled to a photomultiplier tube, providing essentially an all-sky view. The instrument is sensitive to bursts with fluence $> 10^{-6}$ ergs/cm^2 and records a burst once every 3–4 days. The solar probe is presently over the North polar region (June 1995) of the sun.

The SROSS satellites

The Indian SROSS-C and SROSS-C2 satellites carrying the GRB experiment were launched on 20 May 1992 and 4 May 1994 respectively, with the objective of

a) monitoring GRBs in the energy range 20 keV–3 MeV with a sensitivity to bursts of fluence $> 5 \times 10^{-6}$ ergs/cm^2
b) monitor intensity variations with high time resolution (2 ms)
c) search for periodicities in the time histories
d) determine the evolution of the energy spectra with time and
e) search for cyclotron absorption features in the 20–100 keV energy range and look for possible redshifted annihilation radiation line in the 400–500 keV range.

Both satellites were of octagonal prismoidal shape, carrying the payload on their topdeck, and launched into a 45° inclination low earth orbit. The spin stabilized spacecrafts have their spin axis parallel to the detector view axis and along the negative orbit normal (Figure 3), thereby permitting a half sky coverage less the region (~ 34%) occulted by the earth due to low earth orbit. In addition, due to the high inclination orbit, about 30% of observing time is lost owing to passage through the South Atlantic Anomaly (SAA) and high latitude regions.

The experiment on SROSS-C had two sodium doped caesium iodide scintillation detectors, a main (44 cm^2 area), a redundant (11 cm^2 area) and a common microprocessor (CDP1802) based electronics[59,60]. The SROSS-C2 payload (Figure 4), however, carries only the main detector with its associated electronics[61]. The SROSS-C payload could record data on only one event between consecutive readouts, while the payload onboard memory in the case of SROSS-C2 is enhanced to hold the data on seven events. This feature has enhanced the duty cycle of the payload from ~ 40% in SROSS-C to about 70% in SROSS-C2.

SROSS GRBs

The experiment flown on SROSS-C worked very satisfactorily during the entire mission life of 55 days. It recorded 3 candidate GRB events, which were however not detected by GRB detectors onboard other satellites in the interplanetary space and hence remained unconfirmed[62].

SROSS-C2, which has been in orbit for the past one year, has a life expectancy of about 5 years. After the placement of the satellite in its final orbit (620 × 430 km) on 10 July 1994, the GRB payload has been operating flawlessly in meeting with its design goals. The payload records an average of one or two events every month and has recorded 15 events up to 30 May 1995. Table 1 gives the shortlisted SROSS-C2 GRB events. Of these, 13 events have so far been confirmed for detection onboard other GRB monitors. In order to confirm an event, the structure, rise time, decay time, duration and intensity of the temporal profiles recorded on different satellites have to agree with one another within their errors of measurement. Events coincident with Ulysses, BATSE of CGRO, and WIND are marked U, B and W respectively.

The event detected by SROSS-C2 on 6 January 1995 was not detected by Ulysses, presumably due to its faintness. For the event in orbit 1448, Ulysses had a rate increase in its detector, but not a trigger. As the Sun was within the field of view of the detector, this event could possibly be of solar origin. The sensitivity of the SROSS–GRB payload, implies a detection rate of ~ 18 events per year and is consistent with the observations. A mosaic of a few events is shown in

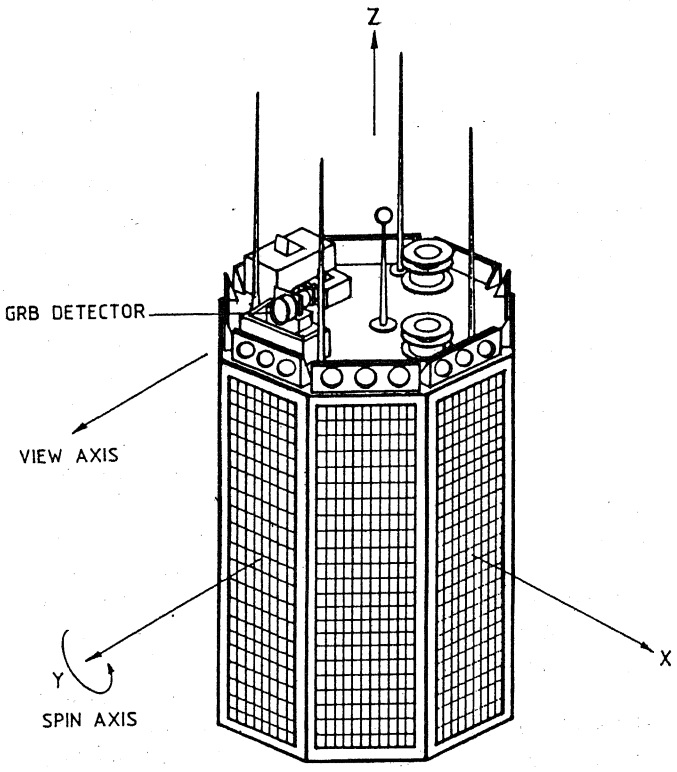

Figure 3. SROSS-C2 with GRB detector mounted on the top deck.

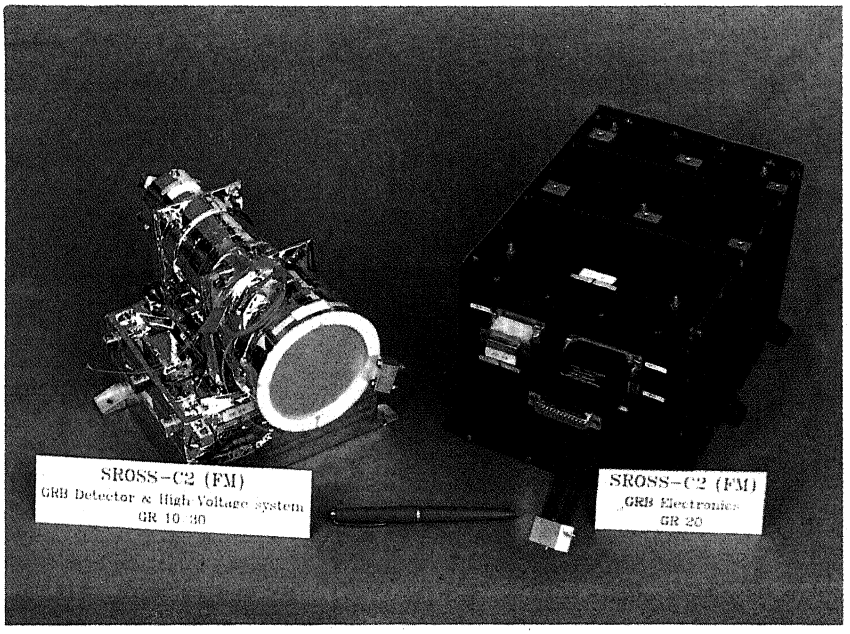

Figure 4. The gamma ray burst payload.

Table 1. SROSS-C2 GRB events

Event orbit	Event date	Time (UT) h m s	Event confirmed by
1126	19 Jul 94	06 00 05.614	U
1296	30 Jul 94	11 01 30.658	U, B
1448	09 Aug 94	11 52 31.791	—
1650	22 Aug 94	20 23 19.878	U
2095	21 Sep 94	05 08 19.368	U, B
2234	30 Sep 94	10 02 06.008	U
2492	17 Oct 94	10 19 59.748	U
3099	26 Nov 94	12 23 05.244	U, B, W

4259	11 Feb 95	02 24 57.626	U, B
5101	07 Apr 95	15 15 31.312	U
5497	03 May 95	18 36 10.626	U, B
5622	12 May 95	00 16 48.280	U, W

U, Ulysses; B, BATSE; W, WIND.

Figure 5. As seen from the table, all confirmed events are coincident with Ulysses, while only 5 are coincident with CGRO. The reason probably could be attributed to the fact that Ulysses being a solar probe in an orbit which is presently out of the ecliptic plane has essentially an all-sky view, while both SROSS-C2 and CGRO being low-earth orbiting satellites undergo earth occultation of sky and loss of observing time due to passage through high latitudes and the SAA.

Most events last typically few tens of seconds, with the exception of two, one on 22 August 1994 and the other on 11 February 1995, which lasted about 400 ms and 128 ms respectively. The weakest burst detected by the payload so far has a fluence of about 3×10^{-6} ergs/cm^2. The normal characteristics of GRBs, viz. bimodal distribution of burst durations i.e. < 2 s and > 2 s; spectral hardness and intensity correlation etc. are all seen in our data base, albeit its small size. Analysis of all the confirmed events is being reported elsewhere.

Tracking down the GRB sources

With a few of the recent counterpart observations on Soft Gamma Repeaters being successful, it appears that these might be a separate population of sources, probably related to young pulsars in supernova remnants. However, the nature and origin of 'classical' GRBs remains one of the most compelling astrophysical problems, in view of the isotropy results of BATSE on CGRO. The solution to this problem, at the moment, demands observations that will settle the burster distance scale unambiguously. It is thus evident that a reliable statistical analysis and identification of the phenomenon with a definite class of astronomical objects requires the knowledge of as many source locations as accurately as possible. With each IPN, the triangulation baselines have grown progressively longer and have reached around 6 AU, the longest ever, when Ulysses was close to Jupiter, permitting localizations as fine as 0.1 arcmin^2. Although greater than 2000 GRBs have been recorded till date, about a 1000 or so are localized to a few degrees and only a dozen to few arcmin^2 (ref. 63).

The future efforts on tracking down the sources rely

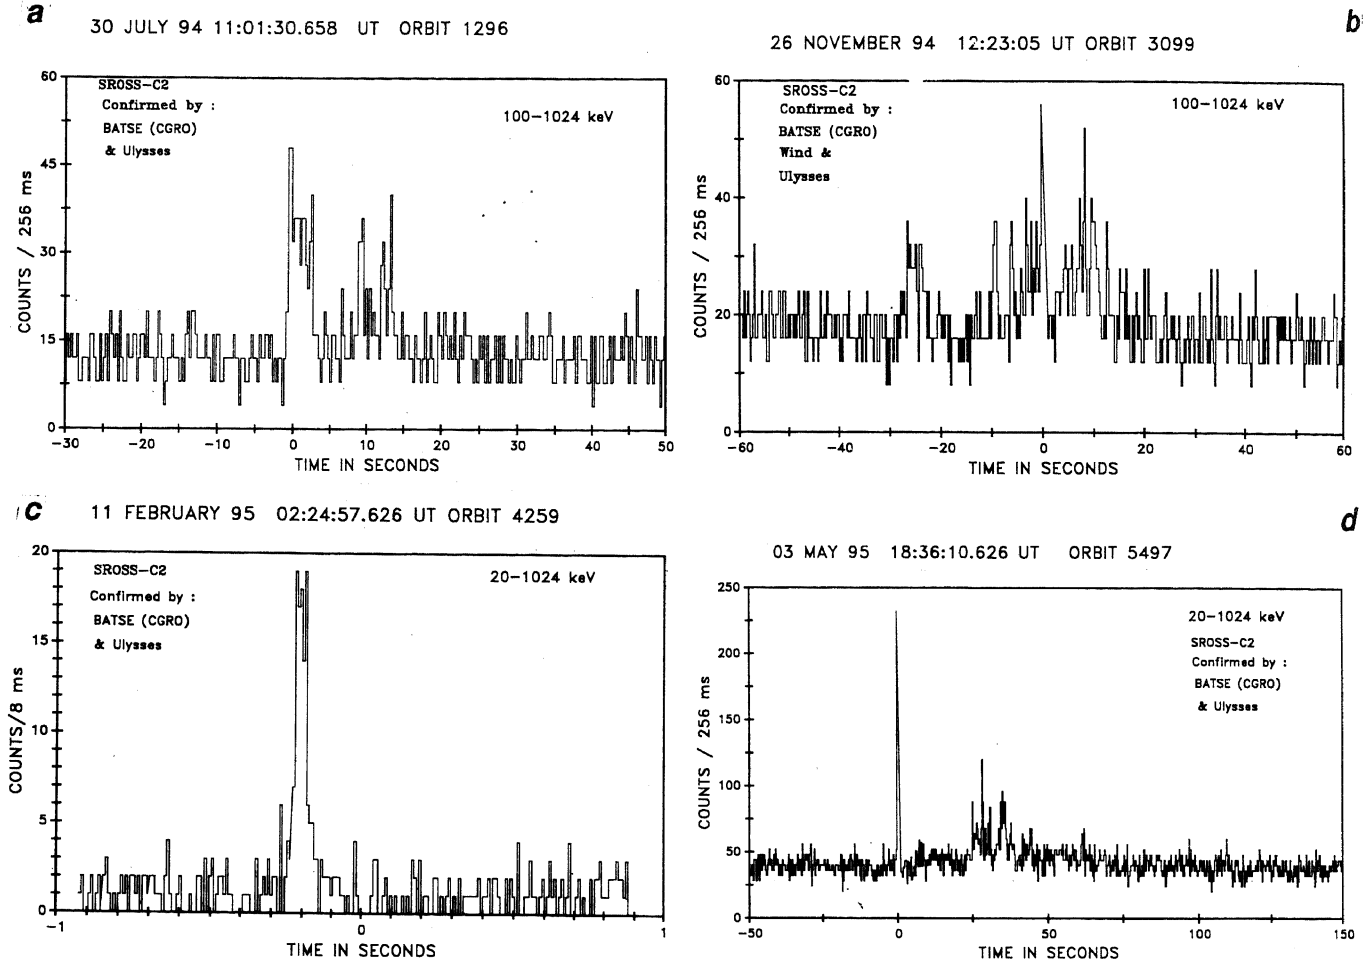

Figure 5. A few events detected by SROSS-C2.

on rapid response campaigns between CGRO and fast slewing ground-based radio and optical telescopes. Multi-wavelength (gamma, X-ray and ultraviolet) observations are planned onboard the high energy transient experiment[64] (HETE) scheduled for launch in late 1995. HETE intends to localize GRBs in the UV band to arcsecond accuracy, although it is not proven that optical flashes accompany GRBs.

Since all near-earth spacecrafts undergo earth occultation, complete sky coverage at all times requires more than one instrument in near-earth space. The GRB experiment on SROSS-C2 is expected to fulfil this function and complement data obtained by CGRO and GRANAT in near-earth space. While the SROSS-C2 payload is not designed to participate in any rapid response campaign, or conduct multiwavelength observations, it is expected to detect about 80–90 bursts during its 5-year life time, of which most are likely to be coincident with Ulysses and WIND. Since Ulysses, WIND and SROSS-C2 do not independently possess the ability to localize GRBs, the class of events, coincident between these three spacecrafts, but not necessarily coincident with CGRO, would form a complement to the CGRO–Ulysses–WIND data base. We hope to record at least a dozen such events. With this, SROSS-C2 would play an important role in the international efforts of tracking down the GRB sources.

Quantum Monte Carlo techniques: Chemical applications

Charusita Chakravarty

Department of Chemistry, Indian Institute of Technology, New Delhi 110 016, India

Quantum Monte Carlo (QMC) methods are stochastic simulation methods for quantum many-body systems. Here we provide an overview of QMC methods designed for simulation of atomic and molecular systems, and discuss main ideas behind the variational, diffusion and path integral QMC methods. We also review application of these techniques to some problems of interest in chemistry.

> The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are (thus) completely known, and the difficulty is only that the exact application of these laws leads to equations much too complicated to be solvable. It therefore becomes desirable that approximate practical methods of applying quantum mechanics should be developed, which can lead to an explanation of the main features of complex atomic systems without too much computation.

SINCE P. A. M. Dirac wrote the above lines in 1929 (ref. 1), both the range of approximate quantum mechanical methods, and the notion of what constitutes 'too much computation' have undergone dramatic changes.

Over the past few decades, chemists have come to understand the interactions and dynamics of small molecules and clusters very well. Both theory and experiment can, for instance, provide a very accurate

understanding of the H_2O molecule and a reasonable one of the dimeric and trimeric aggregates $(H_2O)_2$ and $(H_2O)_3$ (refs 2,3). The macroscopic end of the scale, such as the thermodynamics and spectroscopy of bulk liquids and solids is again well understood from a phenomenological point of view; for example, bulk water is known to be a complex fluid with an elaborate phase diagram[4]. The conceptual connection between microscopic and macroscopic behaviour is made by statistical mechanics. Computer simulation methods complement the elegant but simplified statistical mechanical models by providing a much clearer connection between experimental and calculated quantities, the ability to make quantitative or semiquantitative predictions and the opportunity for performing numerical or computer experiments for systems or conditions which may not be easily realizable in a laboratory.

Currently, most simulations are performed using either classical Monte Carlo methods or the molecular dynamics approach[5]. Applications of these methods range from geochemistry to protein structure[6,7]. Both techniques assume the Born–Oppenheimer separation of electronic and nuclear motion. The nuclei are assumed to be classical particles moving according to the Newtonian equations of motion on the electronic potential energy surface (PES). The PES itself is constructed as a sum of pair (or at most three- and four-body) interactions between atoms, i.e. the total interaction energy of a system is assumed to be the sum of the interaction energies between all unique pairs. These few-body potentials are derived from independent studies of small aggregates and provide the necessary simulation input about the details of the microscopic interaction[8]. Classical Monte Carlo techniques generate the equilibrium statistical mechanical properties of a system, usually within the canonical ensemble, such as the average potential energy, structural quantities such as the radial distribution function and phase transition behaviour. For an N-atom system, such Monte Carlo techniques construct a random walk through the $3N$-dimensional configuration space with a bias such that for sufficiently long walks, a set of configurations, $\mathbf{x}$, distributed according to the Boltzmann formula $e^{-\beta V(x)}$ is generated. If N is sufficiently large and suitable boundary conditions are applied, then equilibrium properties of the bulk system can be generated. MC integration is an inherently multidimensional approach with a statistical accuracy in the results that is proportional to $(n/\tau)^{1/2}$, where n is the number of MC configurations and τ is a measure of the degree of correlation between successive configurations. While τ does tend to increase with dimensionality of the system, this dependence is generally small. Consequently, MC methods scale relatively favourably with system size, in terms of computational cost.

Classical molecular dynamics, instead of using a random walk approach, involves numerical integration of the classical equations of motion to generate the trajectory of the N-particle system through phase space. Provided certain conditions are satisfied (ergodicity, sufficient length of trajectory and the like), the phase space points sampled during the course of an MD run provide information on both the equilibrium and dynamical statistical mechanical quantities. Thus, unlike MC, MD methods can provide time-correlation functions related to transport properties and spectroscopy. However, MD can prove inefficient relative to MC for systems with multiple time scales. For example, in binary solid solutions, the rates of diffusion of the two species are much slower than the high frequency lattice vibrations[9].

An important development in the past decade has been the formulation of *ab initio* MD methods, which attempt to overcome the problems of inadequate parametrization of the PES surface. Such problems are most acute in the case of semiconductor and metal systems; the delocalized nature of the valence electrons in such materials implies that the pair potential approximation is very poor. This is also true for chemical reactions where changes in electronic structure and nuclear configuration are very strongly correlated. Polarizability effects are also notoriously hard to incorporate within a pair potential approach. The *ab initio* MD methods attempt to solve this problem by solving the electronic structure problem simultaneously with the integration of the classical equations of motion and, in principle, require no input other than electronic and nuclear masses and electric charges.

The most successful *ab initio* MD approach to date is the Car–Parinello (CP) formulation. The CP technique uses the Born–Oppenheimer approach to separate motion of the ionic cores from that of the valence electrons. The motion of ionic cores is treated by using classical MD equations of motion. To obtain a suitable electronic PES, the ground state electronic energy for any given ionic configuration must be found. To do this both accurately and efficiently, three important simplifications are made: (i) Density functional theory (DFT) is used to model electron–electron interactions. DFT is a mean-field approach which introduces electron correlation effects in an approximate way. Results for a variety of ground state properties using DFT have been shown to be accurate to within a few per cent. (ii) Pseudopotential theory is used to model electron–ion interactions. Pseudopotentials smooth out the strongly varying regions of the potential for small ion–electron distances while retaining the salient characteristics of valence electron in a bulk medium. (iii) Dynamical minimization techniques are based on the insight that the variational solution to the density functional equations can be obtained by a constrained optimization scheme in which basis functions for the electronic structure problem are

treated as dynamical variables. The advantage of this approach is that the real-time dynamics of the ionic cores and the fictitious dynamics associated with the electronic variables can be coupled together in a very powerful computational scheme. The net result is that the classical motion of atoms on the ground state Born–Oppenheimer PES is obtained. The CP method has provided remarkable results for many problems of current interest in materials science[10]. The technique is at least an order of magnitude more expensive than classical MD.

Quantum Monte Carlo (QMC) methods, as the name suggests, are stochastic simulation methods for quantum many-body systems[11–16]. The term QMC covers a battery of techniques used in a variety of fields such as condensed matter physics, nuclear physics, statistical mechanics and chemistry. This review is intended to provide an overview of QMC methods designed for simulation of atomic and molecular systems of interest in chemistry.

One situation in which QMC methods become essential for chemical systems is when the atomic nuclei are sufficiently light or temperatures are sufficiently low that the approximation of treating nuclear motion classically becomes a poor one. For example, quantum effects are important in the water and ice because of hydrogen-bonding. Electron and proton transfer processes, vital to many biochemical processes, are intrinsically quantum mechanical. Many solids such as ammonium halides and solid H_2 show phase transitions, with large isotope effects indicative of strong quantum effects[4]. Even solid argon must be modelled with significant quantum corrections to thermodynamic properties[5].

Electronic structure problems are a second area of chemistry where QMC methods are applicable when accuracy requires improvements over density functional theory (the basis of Car–Parrinello) or when the Born–Oppenheimer approximation fails due to strong coupling between nuclear and electronic motion[13].

The review is organized as follows. Sections 1, 2 and 3 present the essential ideas behind the variational, diffusion and path integral Monte Carlo methods respectively. Section 4 briefly reviews the application of QMC methods to some problems of interest in traditional chemistry where the simulations provide interesting insights and connections between experimental data and simplified theoretical models.

1. Variational quantum Monte Carlo methods

The variational Monte Carlo (VMC) approach is based on the variation principle which states that for a given Hamiltonian $\hat{H}$, the energy E_t associated with a trial wavefunction ψ_t, defined as

$$E_t = \int \psi_t^* \hat{H} \psi_t \, d\tau / \int \psi_t^* \psi_t \, d\tau \qquad (1)$$

will always be greater than or equal to the exact ground state energy E_0 of the system[12]. Minimizing E_t with respect to the parameters of ψ_t provides the best approximation to the ground state wavefunction within the limitations of a given functional form. Conventional quantum chemical methods expand the trial wavefunction ψ_t as a linear combination of a suitable set of basis functions and then utilize the variation theorem to obtain the optimum set of linear combinations. While such methods can provide very accurate energies and wavefunctions, they scale very inefficiently with the system size or dimensionality. For example, configuration interaction methods scale as N^7, where N is the number of basis functions, implying that such studies are only feasible for small molecules.

VMC methods use the favourable scaling of Monte Carlo methods with system size by interpreting $\psi_t^* \psi_t$ as a probability distribution. Standard random walk methods can be used to create a set of configurations, $\mathbf{x}$, distributed according to $\psi_t^*(\mathbf{x}) \psi_t(\mathbf{x})$ and E_t can be defined as the average over this set of configurations of the local energy, $E_t = \hat{H} \psi_t(\mathbf{x})/\psi_t(\mathbf{x})$. The form of the trial wavefunction is usually derived from a knowledge of the basic physics of the problem and the parameters can then be optimized by minimizing E_t or, better still, the variance in E_t.

VMC methods are computationally relatively inexpensive and can provide considerable physical insight. The limitations of VMC methods are two-fold: (i) the accuracy of the calculation is limited by the choice of functional form of ψ_t; (ii) being essentially a ground state method, information on excited state energies and wavefunctions is difficult to obtain though not impossible. Despite these limitations, VMC calculations are capable of providing accurate results for a variety of systems. As an example of an application to solid state electronic structure calculation, the bulk cohesive energy of diamond and graphite was calculated to within 1% of the experimental value using VMC[17]. VMC simulations of helium have provided very accurate results, when compared with experiment, for properties of helium in the bulk, at surfaces and in droplets[18].

2. Diffusion Monte Carlo methods

Diffusion Monte Carlo (DMC), like VMC, is a zero-temperature approach that is geared towards finding the ground state wavefunction. Unlike VMC, which provides an upper bound to the ground state energy, DMC is, in principle, capable of generating the *exact* ground state energy and wavefunction[11–16].

The starting point of the DMC method is the time-dependent Schrödinger equation

$$i\hbar \frac{\partial \Psi}{\partial t} = \hat{H} \Psi , \qquad (2)$$

where t is the time coordinate. If t is treated as an imaginary quantity $t=-iu$ (where u is real), then the above equation can be rewritten as:

$$-\hbar \frac{\partial \Psi}{\partial u} = \hat{H}\Psi, \tag{3}$$

or

$$\Psi_{\text{final}} = e^{-u\hat{H}/\hbar}\Psi_{\text{initial}}. \tag{4}$$

By an analogy with the density operator, $e^{-\beta\hat{H}}$, used in statistical mechanics, imaginary time in the above equation can be interpreted as proportional to the inverse temperature, $\beta = 1/k_B T$ such that $u = \beta\hbar$, T is the absolute temperature and k_B is the Boltzmann constant. It can be shown that regardless of the choice of Ψ_{initial}, Ψ_{final} will converge exponentially to the ground state wavefunction Ψ_0 with energy E_0 in the limit $\beta \to \infty$, $T \to 0$. If it is assumed that the ground state wavefunction is nodeless, as is the case for bosons or distinguishable particles, then the above equation can be interpreted as the evolution of an initial, arbitrary probability distribution to the final stationary state distribution given by Ψ_0. To understand the basis of the computational scheme, consider the evolution of the distribution over a very small imaginary time interval, $\varepsilon = \beta/M$, from time u_i to u_{i+1}. Then it is possible to factorize $e^{-\beta\hat{H}/M}$ as $e^{-\beta\hat{K}/M}$ $e^{-\beta\hat{V}/M}$, where $\hat{K}$ and $\hat{V}$ are the kinetic and potential energy operators respectively. Considering a one-dimensional system for notational simplicity, the distribution at time u_i can be represented as a set of points distributed on the x-axis according to the initial distribution $\Phi_i(u_i, x_i)$. To carry out the evolution over the time interval ε, we first apply $e^{-\beta\hat{V}/M}$ on $\Phi_i(u_i, x)$ to give $e^{-\beta(V(x)-E_T)/M}\,\Phi_i(u_i, x)$, where $V(x)$ is measured with respect to some energy E_T. This will imply that in regions of low potential energy, the probability distribution will be enhanced whereas in regions of high potential energy, the distribution will be attenuated (birth/death process). To complete the evolution we must then act using the operator $e^{-\beta\hat{K}/M}$ which results in

$$\sqrt{m/2\pi\varepsilon}\; e^{-m/2\varepsilon(x_{i+1}-x_i)^2}\; e^{-\beta V(x_i)/M}\; \Phi_i(u_i, x_i). \tag{5}$$

Note that the positions obtained at the end of the time step, x_{i+1}, are Gaussian distributed about the positions x_i at time u_i. This can be interpreted as a diffusion step with diffusion constant $\hbar/2m$. Thus a short-time propagation corresponds to a birth/death step followed by a diffusion step. Repeated application of such short time evolutionary operators will result in convergence to the ground state.

For all but the simplest system, the naive DMC algorithm described above must be made more efficient by introducing importance sampling. Importance sampling biases the random walk towards the most important regions of configuration space by using the information provided by a good approximate wavefunction, usually derived from a VMC calculation. A different formulation of this zero-temperature approach, equivalent to the DMC method, is Green's Function Monte Carlo (GFMC).

Monte Carlo methods require the definition of a probability distribution function that is always positive. In the case of VMC simulations, the modulus squared of the wavefunction provides a positive probability distribution function. In DMC simulations of bosons or distinguishable particles, the nodeless ground state wavefunction can be treated as a probability distribution. In the case of interacting fermions, however, the ground state cannot be assumed to be nodeless. The anti-symmetrization requirement for fermions implies that nodes will exist in the wavefunction whenever positions of two fermions with identical spins coincide. Continuity of the wavefunction and its first derivative then implies that the wavefunction must change sign at these nodal planes. Consequently, the interpretation of the ground state wavefunction as a probability distribution is invalid, leading to the well-known 'fermion-sign' problem. Fixed-node methods which are surprisingly accurate though not, in principle, exact, have been developed to circumvent this problem. A very important application of this fixed-node DMC technique has been in deducing the exchange correlation functional for the uniform electron gas, which forms the basis of most density functional and *ab initio* MD calculations[19].

3. Path integral Monte Carlo method

Path integral Monte Carlo (PIMC) techniques allow for simulations of quantum many-body systems in the canonical ensemble (constant number N, volume V and temperature T). The equilibrium properties of a system in the NVT ensemble are determined by the canonical partition function, Q. For a quantum system, Q must be expressed as a trace over the density operator $e^{-\beta\hat{H}}$; evaluation of the trace in the coordinate representation then leads to:

$$Q = \text{Tr}\{e^{-\beta\hat{H}}\} = \int d\mathbf{x}\, \langle \mathbf{x}|e^{-\beta\hat{H}}|\mathbf{x}\rangle, \tag{6}$$

where $\mathbf{x}$ is the position vector for the N-particle system. Path integral methods interpret $e^{-\beta\hat{H}}$ as a propagator in imaginary time (note the similarity with DMC) and express the density matrix elements as the functional integral

$$\langle \mathbf{x}|e^{-\beta\hat{H}}|\mathbf{x}'\rangle = \int \mathcal{D}(\mathbf{x}(u))e^{-S(\mathbf{x}(u))/\hbar}, \tag{7}$$

where the integral represents the sum over all possible paths, $\mathbf{x}(u)$, in imaginary time u which satisfy the condition that $\mathbf{x}(0) = \mathbf{x}$ and $\mathbf{x}(\beta\hbar) = \mathbf{x}$. The weighting of individual paths is given by the exponential of the

action in imaginary time, $S(\mathbf{x}(u))$. Note that only cyclic quantum paths with the same initial and final point can contribute to Q. The classical path is the path of least action[20].

PIMC methods involve finding paths which contribute the most to the partition function. For example, in the discretized path integral approach, any quantum path is represented as a set of configurations, $\{\mathbf{x}_i\}$, at equispaced intervals in imaginary time, $u = 0$, $(\beta\hbar/M)$, $(2\beta\hbar/M)$, ..., $\beta\hbar$. Using this representation, Q for an N-particle system can be written as

$$Q = \frac{1}{N!}\left(\frac{Mm}{2\pi\beta\hbar^2}\right)\int d\mathbf{x}_1\, d\mathbf{x}_2 \ldots d\mathbf{x}_M \times \exp\left\{\frac{-Mm}{2\beta\hbar^2}\,(x_{12}^2 + x_{23}^2 + \ldots x_{M1}^2)\right\} \times \exp\left\{\frac{-\beta}{M}\,(V(\mathbf{x}_1) + V(\mathbf{x}_2) + \ldots V(\mathbf{x}_M))\right\}, \quad (8)$$

where $\mathbf{x}_{ij} = |\mathbf{x}_i - \mathbf{x}_j|$. The partition function in equation (8) has the same structure as the classical configurational integral with $3NM$ spatial degrees of freedom. The interpretation of the above partition function is, however, somewhat novel. In the classical limit, a particle is characterized by 3 position degrees of freedom. In the discretized path representation, the single quantum particle is replaced by a cyclic polymer of M subunits, with adjacent subunits held by a harmonic interaction; the external potential felt by each subunit is $V(\mathbf{x}_i)/M$. The average extent of the polymer is proportional to the thermal de Broglie wavelength of the particle. Equation (8) can be used directly in conjunction with the Metropolis algorithm to simulate a many-particle quantum system. It is, however, often computationally more efficient to employ alternative representations of the path integral[21]. The common feature of all such PIMC methods is the quantum classical isomorphism – by introducing auxilliary degrees of freedom (such as the $M-1$ additional position degrees of freedom for the polymer subunits), the trace over the density operator is written as a classical configurational integral of much higher dimensionality. The fermion sign problem present in DMC recurs also for the finite temperature formulation and methods analogous to the zero-temperature are currently being devised. An interesting and unsolved problem is whether the imaginary time PIMC formulation can be adapted for real-time problems. While this is one approach towards achieving the tantalizing goal of devising a simulation method for many-body quantum dynamics, so far it has met with little success[21].

PIMC methods have been applied extensively to molecular systems. The best studied system is liquid ^{4}He which shows a Bose–Einstein transition to a superfluid state; simulation results compare very well to the experiment[12]. Good approximation methods for finite temperature fermionic systems have been developed recently and applied to liquid ^{3}He and electronic structure[22,23]. An interesting possibility is combining PIMC methods for nuclei with Car–Parinello techniques for obtaining the electronic structure. While prohibitively expensive at present for bulk systems, it has been applied to CH_5^+. The structure of CH_5^+ has long been controversial with arguments that it is a unique carbonium atom as opposed to the theory that it is the prototype for a nonclassical hyper-coordinate carbocation, with a ground state dominated by 3-centre-2-electron bonding. The combined PIMC and *ab initio* MD calculations indicate that the quantum ground state is dominated by 3*c*-2*e* bonding[24,25].

4. Some applications

Surface adsorption

The importance of surface adsorption, from practical applications in heterogeneous catalysis to theoretical models for phase transitions in two-dimensional systems, does not require emphasis. As a result, classical simulation of surfaces and interfaces is by now a well-developed field[26]. Appreciable quantum effects can, however, be expected for light adsorbates, e.g. H_2, He, Ne, N_2 and CO, specially at low temperatures. One of the first surface adsorption problems to be studied by PIMC was ^{3}He and ^{4}He adsorption on graphite[27]. The quantum simulations corroborated experimental results for the different phase diagrams of the two isotopes and provided interesting insights into the microstructure associated with different phases. In addition, DMC/GFMC calculations have been carried out to explore the zero temperature limit of the He/graphite system[12]. In contrast to atomic substrates, diatomic molecules can exhibit a range of orientational transitions. For example, N_2/graphite shows a herringbone transition; PIMC simulations have quantified that the lowering of the transition temperatures due to quantum effects is 10% (30 K) (ref. 28). The CO/graphite system is analogous to the N_2 adsorption problem except for a heat capacity anomaly at approximately 5 K. Recent PIMC simulations have shown that this must correspond to the head-to-tail ordering transition for the two-dimensional CO system[29]. To my knowledge, there have been no zero-temperature studies of molecular adsorption, largely because interest in this area centres on finite temperature phase transitions.

Solvated electrons

The solvated electron; a 'free' electron trapped in a cavity formed by solvent molecules, plays an important role in a variety of chemical phenomena. The hydrated

electron has been shown to be a transient species of crucial importance in solution photochemistry since its identification more than 30 years ago[30,31]. The solvated electron is central to the metal–insulator transitions observed in alkali metal–ammonia solutions and related systems. The localized versus extended states responsible for the metal–insulator transition are also connected to electron mobilities in fluids and other disordered media; therefore the general problem of excess electron mobilities in a variety of solvents has attracted much theoretical and experimental attention[32–34]. The structure of a solvated electron in a fluid will be determined by the competition between two factors: a tendency to delocalize and occupy as large a volume as possible in order to minimize the kinetic energy and a tendency to minimize potential energy by optimizing electron–solvent interactions. In the case of the dominant contribution to the electron–solvent interaction being an excluded volume or repulsion interaction, the electron will tend to localize in regions of low fluid density. If the attractive interactions can be enhanced in these low density traps (for example, by the presence of oriented solvent dipoles) then the size of the cavity can be substantially reduced. The fact that the characteristics of solvated electron systems will depend on this type of complex interplay between a variety of factors, makes simulations a virtual necessity. Different simulation techniques can then be used to provide complementary information on these systems.

Among the best-studied solvated electron systems, both from an experimental and simulation perspective, are the alkali metal–ammonia solutions which have a long experimental history[35]. Alkali metals dissolve in liquid ammonia and, at very low concentrations, form a light blue solution. Spectroscopic and other evidences indicate that, as in the case of F-centres in alkali halides, the blue colour is due to the optical spectrum of an isolated solvated electron. As the concentration of metal is increased, the magnetic susceptibility falls, indicating that some type of spin pairing process is in operation. However, as the metal concentration increases, a metal insulator transition takes place and a bronze-coloured liquid metal is formed. At still higher concentrations, metallic solid compounds are formed. The dilute limit is ideally treated by PIMC methods[36]. The results show the trapping or localization of single electrons in solvent cavities with an effective size of about 4 Å. In fact, a transition from a delocalized to a localized, trapped state is seen as solvent concentration is increased. The results of the simulation agree well with experiment as well as with predictions of the RISM-polaron theory[37]. The metallic limit with high electron concentration can be treated by Car–Parrinello methods[38–40]. The intermediate regime, especially where spin-pairing occurs, can be treated by both approaches. In the spin-pairing regime, the simulations show that electron-pairs form singlet states which occupy a peanut-shaped cavity with the two peaks in the electron density separated by 7 Å. The triplet state is unstable with respect to the singlet state by approximately 0.6 eV. Thus, this series of simulations on the alkali metal–ammonia solutions has provided considerable insight into the microstructure and dynamics associated with the metal–insulator transition.

Quantum clusters

Clusters have attracted much attention by virtue of being small systems which bridge the transition from molecular to bulk properties[41–44]. While clusters can show properties similar to those of bulk matter, e.g. collective behaviour analogous to a phase transition, they are sufficiently small to be studied at the same level of microscopic detail as molecular systems. In this section, some of the applications of QMC methods to quantum clusters are summarized. Quantum clusters denote small, finite atomic or molecular systems (about 10–1000 atoms) where the nuclei have appreciable quantum character. Recent experiments on rare-gas–SF_6 clusters have added to the interest in quantum clusters[45]. Electronic structure aspects, of special relevance to metallic and semiconductor clusters, are not considered here. It should be pointed out that cluster simulations have played an important role in the development of QMC methods; for example, one of the first applications of VMC and GFMC methods was to helium clusters to test the reliability of liquid drop models for clusters[45].

Atomic clusters, such as those of He, Ne, H_2 and D_2 have been very useful in understanding quantum effects on phase transitions[46–54]. For example, ^4He_n with $n > 60$ shows clear remnants of the bulk superfluid transition and QMC simulations can provide a corresponding microscopic model[53]. Bulk melting has its cluster analogue and has been studied in clusters with a view to understanding the role played by quantum fluctuations in modifying phase transition characteristics. For example, Figure 1 shows the lowering of the position and height of the specific heat curve for a Ne_{13} cluster due to quantum effects[48]. Increasing quantum delocalization can be shown to result in a cluster solid–liquid transition analogous to the thermal melting transition[55]. The effects of such delocalization can be seen in Figure 2, where the angular distributions for the Ne_{13}, $(para\text{-}H_2)_{13}$ and $(ortho\text{-}D_2)_{13}$ are compared with those of a classical thirteen atom Lennard–Jones cluster[49]. A purely quantum analogue of the classical binary phase separation can be shown to occur in isotopically mixed clusters using PIMC methods[56]. Figure 3 shows the density profiles for the two isotopic species in a mixed *para*-H_2/*ortho*-D_2 cluster; the heavier isotope can be seen to be preferentially located in the cluster interior.

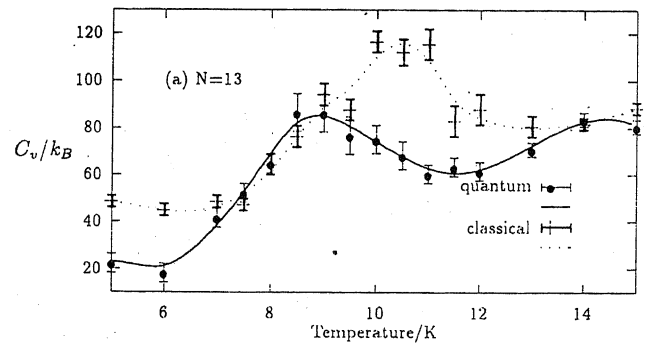

Figure 1. The specific heat, C_v/k_B, as a function of temperature for a Ne_{13} cluster. Results from path integral quantum Monte Carlo and classical simulations are compared.

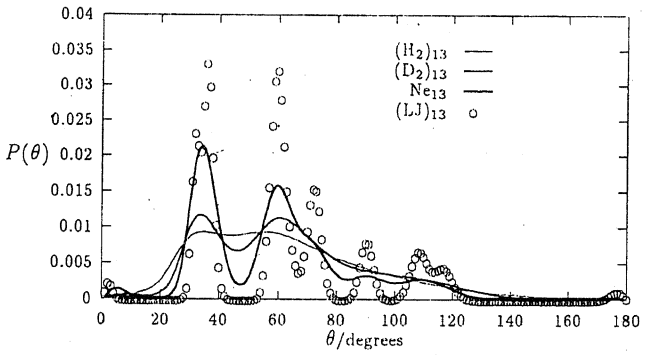

Figure 2. Angular distributions, $P(\theta)$, for thirteen atom clusters at 5 K. The distribution for the classical Lennard–Jones cluster, $(LJ)_{13}$, is compared with that for quantum clusters of Neon, *para*-H_2 and *ortho*-D_2. The latter two species can be treated as pseudo-atomic systems interacting via a spherically symmetric pair potential at low temperatures. The peak at 60° is characteristic of the icosahedral symmetry of small Lennard–Jones clusters.

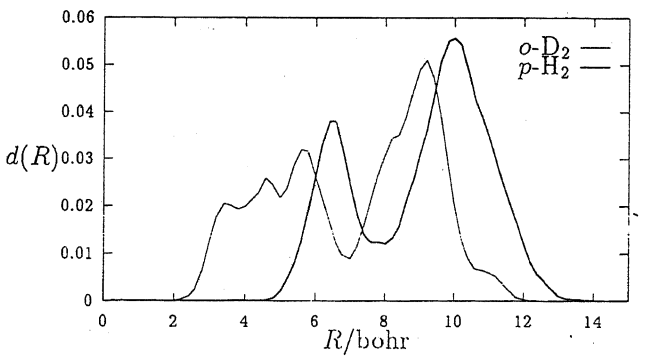

Figure 3. Radial density profiles, $d(R)$ for the two isotopic species in the $(P\text{-}H_2)_9(O\text{-}D_2)_9$ cluster at 2.5 K. The radial density profile is a measure of the probability of finding a particle of a particular species at a distance R from the centre of mass of the cluster.

A second category of clusters with large quantum effects are the so-called solvent clusters such as $(H_2O)_n$, $(NH_3)_n$ and $(HF)_n$. Understanding the structure and dynamics of such systems is of particular importance from the point of view of solvation, liquid structure and hydrogen bonding. Small aggregates of two, three or four monomers have been intensively studied by QMC methods (mostly DMC). Such studies are very valuable from the point of view of deriving accurate intermolecular potentials by comparison and fitting to spectroscopic data.

Electron transfer

Electron transfer is fundamental to a variety of chemical and biochemical processes. An electron transfer process may be represented as:

$$\text{Acceptor(A)} + \text{Donor(D}^-\text{)} \rightarrow \text{A}^- + \text{D}, \qquad (9)$$

where A and D may be ions or molecules and the reaction takes place in a dielectric solvent. A simple model for electron transfer envisages the electron as being trapped on one of two wells, localized on either A or D, with shapes and relative energies of the two wells determined by the classical degrees of freedom of the nuclei composing A, D and solvent. The electron transfer process between the two wells corresponds to a tunnelling transition. In the limit that the coupling of the electronic (quantum) and classical degrees of freedom is weak, the rate constant for electron transfer can be related to the tunnelling splitting and a Franck–Condon factor. PIMC calculations can be used to calculate the magnitude of the tunnelling splitting[57]. The computation of the tunnelling splitting assumes a large scale separation between the frequency of tunnelling (or inter-well) and intra-well motions. Tunnelling paths correspond to quantum paths which connect the two wells. The fraction of imaginary time spent in the barrier region along such a path will be small because the potential energy in the barrier region is high. This type of rapid process or instanton is then said to correspond to a kink in the quantum path and the tunnelling constant can be related to the free energy required to create a kink in the quantum path. Estimation of this free energy can be accomplished in MC simulations by standard thermodynamic integration methods. The Franck–Condon factor can be related to fluctuations in the relative energy of the two potential wells and estimated from classical MC or MD simulations. An ambitious application of this approach has been in explaining some of the unusual features of the primary electron transfer step in bacterial photosynthesis[58,59]. It should be noted that the above approach estimates a dynamical quantity, the rate constant, in terms of equilibrium thermodynamic averages[60].

This can be shown to be a plausible approximation for many systems and has been applied to calculate rates for quantum processes such as proton transfer and hydrogen chemisorption[61,62].

Vitamin C: A potential saviour against free radical-induced oxidative damage

Indu B. Chatterjee, Chinmay K. Mukhopadhyay and Mrinal K. Ghosh

Dr B. C. Guha Centre for Genetic Engineering and Biotechnology and Department of Biochemistry, University College of Science, Calcutta 700 019, India

Scurvy is the foremost nutritional-deficiency disease that has caused maximum suffering in recorded history. Although research on vitamin C started in 1753, the biochemical functions of the vitamin described so far appear to be nonspecific. This paper is a short review indicating that vitamin C protects mammalian tissues from oxidative damage and that its function is specific. Since oxidative damage is supposed to be a physiological event associated with degenerative diseases and aging, vitamin C appears to be a saviour in protecting us against aging and degenerative diseases.

OXYGEN sustains life, but oxygen is not absolutely friendly. The function of oxygen is to act as a terminal electron acceptor. Usually oxygen receives four electrons on a concerted fashion to produce water, but often it is reduced by single electron to produce oxygen-free radical ($O_2^{\cdot-}$) and reactive oxygen species (ROS), such as H_2O_2, $OH^{\cdot}$ and ferryl. ROS is highly toxic and extremely damaging to biological systems. If not properly scavenged, it results in oxidative damage such as lipid peroxidation, protein oxidation and DNA damage. Oxidative damage has been implicated in several degenerative diseases including inflammation, arthritis, cataract, atherosclerosis, cardiovascular diseases, cancer as well as aging[1-7]. A simple but effective way to prevent these degenerative diseases would be to prevent oxidative damage. A cell's major defence against free radical-mediated damage includes antioxidants like ascorbic acid, vitamin E and glutathione and enzymes like superoxide dismutase, catalase and peroxidases. Sometimes ascorbic acid and vitamin E as well as ascorbic acid and glutathione function as partners in defence[8-11]. Previously, we and others have shown that ascorbic acid is a potential scavenger of $O_2^{\cdot-}$, $^1O_2$, and peroxyl radical[12-15]. In this review, we present a brief account of the discovery of vitamin C, its biosynthesis, and newer insights into its biochemical functions with particular emphasis to indicate that vitamin C (ascorbic acid) is a unique antioxidant and in certain conditions it has a specific role in preventing ROS-mediated oxidative damage of mammalian tissues.

Scurvy and the discovery of vitamin C

Most animals synthesize their own requirement of vitamin C, but a human cannot. Humans are totally dependent upon dietary intake of the vitamin. The knowledge that man cannot produce vitamin C was learnt by experience. But the experience was horrible. During the period of 1500 to 1800 AD, scurvy took a toll of at least two million deaths of sailors[16]. Scurvy also ravaged whole armies and inhabitants of besieged cities. It is perhaps the foremost occupational disease and the nutritional-deficiency disease that has caused most suffering in recorded history[17]. It was the genius of James Lind[18] which banished from the navy the most merciless killer of seamen. In 1753 in his book *A treatise of the scurvy*, Lind pointed out the importance of oranges, lemons and fresh green vegetables in preventing and cure of scurvy. But it took another 175 years to discover the antiscorbutic vitamin by Albert Szent-Györgyi. This discovery was accidental. While extracting and concentrating some redox compound from adrenal glands, Szent-Györgyi isolated some sugar-like crystals about which he was quite ignorant and he called it first 'ignose' [(ig for ignorance and ose for sugar)] and later 'godnose' (God knows)[17]. But the editor of the *Biochemical Journal* objected and he had to give the alternative name hexuronic acid (hex = six). In the same period, Charles Glen King of USA isolated the antiscorbutic factor from lemon juice and named it vitamin C[17]. It showed all the characteristics of Szent-Györgyi's hexuronic acid. It was published in *Science* dated April 1, 1932 entitled 'The chemical nature of vitamin C'. Two weeks later, a note appeared in *Nature* entitled 'Hexuronic acid as the antiscorbutic factor', authored by Svirbely and Szent-Györgyi[17]. But these discoveries were possible only because of the outstanding observation by the Norwegian scientists, A. Holst and his associates. Holst observed that guinea pigs, like humans, were prone to scurvy and could be used for producing experimental scurvy and bioassay of vitamin C. At that time there was quite a flurry as to who should be given the credit for 'discovering vitamin C'. Eventually, Szent-Györgyi received the Nobel Prize for Physiology and Medicine in 1937 in recognition of his discoveries concerning the biological oxidation process with special reference to isolation of vitamin C, but C. G. King, who published five papers and isolated vitamin C, did not. Holst, who made it all possible, died in 1931 without any special honours. Here we see that a scientist, working only for a year in Hopkin's laboratory on a problem with quite

a different objective and without doing a single animal experiment, got the full credit for the discovery of vitamin C. To add to this, in the *Annual Review of Biochemistry* in 1963 (ref. 19), Szent-Györgyi made the comment – 'I was not acquainted with animal tests in this field and the whole problem was for me too glamorous, and vitamins were, to my mind, theoretically uninteresting. Vitamin means that one has to eat it. What one has to eat is the first concern of the chef, not the scientist'.

Biosynthesis of ascorbic acid

While the knowledge of cause and cure of scurvy was clear in 1928–32, the question remained unsolved – How is vitamin C synthesized by most animals and why are humans incapable of producing the vitamin? It took about another thirty years to answer these questions. The most intriguing parts of the problem were the discovery and characterization of two enzymes, namely, aldonolactonase (EC 3.1.1.18, L-gulonolactone hydrolase)[20] and L-gulonolatone oxidase (EC 1.1.3.8, L-gulonolactone : oxygen 2-oxidoreductase) and identification of 2-keto-L-gulonolactone[21–23], an extremely unstable terminal intermediate. Eventually the pathway of biosynthesis of ascorbic acid was completely elucidated by the pioneering work of B. C. Guha (India), C. G. King (USA) and L. W. Mapson (England) and their associates. In animals, ascorbic acid is synthesized from glucose via the glucuronic acid pathway of metabolism[24,25]. In this biosynthetic pathway, L-gulonolactone oxidase is the terminal enzyme. L-gulonolactone oxidase converts L-gulono-1,4-lactone to 2-keto-L-gulonolactone, which is spontaneously converted to ascorbic acid.

Evolution and ascorbic acid biosynthesis

There is a distinct relationship between evolution and the capacity to synthesize ascorbic acid in animals[26–28]. The evolution of L-gulonolactone oxidase (LGO) is species-specific and tissue-specific. LGO is absent in fishes. The enzyme evolved in the kidney of amphibians, resided in the kidney of reptiles, became transferred to the liver of mammals and finally disappeared from the guinea pig, flying mammals, primates including monkeys, apes and humans as well as some highly evolved passeriformes birds[28]. Lack of LGO is the common genetic defect in all these species incapable of synthesizing vitamin C[26,29]. In fact, lack of LGO is an evolutionary loss. Recently, the gene for LGO has been cloned and sequenced by the Japanese group[30–32].

Biochemical functions of vitamin C

Although the pathological syndrome of scurvy was delineated by Lind about 242 years ago, the precise biochemical function of the vitamin remained unclear. One of the reasons is the negative contribution by eminent scientists who had success in one field but were perhaps over-confident in proposing theories in the field of vitamin C which they had not studied in depth in the way they had their original field of work. One single example will suffice to understand this. McCollum, the discoverer of vitamin A, drew the surprising conclusion from his experiments with guinea pigs that it was constipation in the guinea pig, rather than the lack of an unidentified factor in the diet, which was the cause of scurvy[17]. He did not realize that scurvy was a generalized disintegration of all tissues leading to loss of life's total occupation, not to speak only of constipation. In fact, vitamin C had long been neglected. The knowledge that vitamin C is needed for the prevention and cure of scurvy was the cause of ample satisfaction to some people, particularly of the medical profession. Quite a few claims have been made about the biological functions of vitamin C, but most of these are nonspecific[33,34]. Research on vitamin C got a tremendous boost in 1970 and onwards after the publication of a paper in the *Proceedings of National Academy of Science, USA*[35] and a bestseller book, *Vitamin C and the Common Cold*[36] by Linus Pauling. However, Pauling's claim that large doses of vitamin C were beneficial for cold and cancer has not been substantiated by later research. But in spite of the debate, controversy and conflicting results about Pauling's theory, Pauling's message has kept vitamin C research alive. In the five years ending 1981, for instance about 5000 papers were published on vitamin C. But still the precise biochemical function of vitamin C remained controversial. None of the roles of ascorbic acid, described before,[33,34] permits a correlation with the pathologic syndrome found in scurvy, which in reality is a syndrome of generalized tissue disintegration at all levels, both intracellular and extracellular. The generalized tissue disintegration in scurvy is accompanied by subcutaneous and intramuscular haemorrhage in various parts of the body, disruption of collagen being a major cause.

Collagen synthesis

The link between collagen synthesis and vitamin C has dominated our thinking for decades. Collagen is a fibrous connective tissue protein which is abundant in tendons, ligaments, basement membranes, bone matrix and blood vessels. Collagen comprises about one-third of the body protein. The stability of collagen depends upon its triple helix structure, which, in turn depends on the presence of the unique amino acid, hydroxyproline. Ascorbic acid stimulates collagen synthesis by stimulating hydroxylation of proline, which is catalysed by prolyl hydroxylase. Scurvy was thought to be caused due to lack of proper

hydroxylation of proline. However, there is little evidence for direct participation of ascorbic acid in collagen synthesis. The function of ascorbic acid for the stimulation of collagen synthesis is to keep the nonheme iron of prolyl-4-hydroxylase in the active state[37]. During the catalytic reaction, a highly reactive iron–oxygen complex, a ferryl ion, is produced, which subsequently hydroxylates an appropriate proline residue[38]. However, the generation of ferryl ion also proceeds without proline hydroxylation in uncoupled reaction cycles. Ascorbate is utilized as a specific alternative acceptor of the ferryl in these uncoupled reaction cycles. In the absence of ascorbate, prolyl-4-hydroxylase is rapidly inactivated by self-oxidation[38]. It is debatable whether a principal function of ascorbic acid is stimulation of collagen synthesis or prevention of disruption of collagen bundles. Recent evidence from our laboratory indicates that ascorbate protects collagen from ROS-induced oxidative degradation. Moreover, studies both *in vivo* and *in vitro* indicate that ascorbic acid prevents ROS-mediated microsomal lipid peroxidation and protein degradation. These have been discussed later in this paper.

Evolutionary significance

The protective role of ascorbic acid against oxidative damage has evolutionary significance. LGO evolved in the amphibians[26]. The class Amphibia emerged and diversified in the Devonian–Permian, when the atmospheric oxygen concentration increased from 15% to 35% (ref. 39). The water oxygen content was about 0.74% (ref. 39). This would indicate that during evolution of the vertebrates in the terrestrial atmosphere, the tetrapods were exposed to an environmental oxygen concentration of about 47 times that of their aquatic ancestors. This extreme hyperoxia might be a cause of extinction of most of the early amphibians[40]. It is conceivable that only those amphibians that acquired a strong defence mechanism against oxygen toxicity survived successfully. It is known that the form of oxygen responsible for toxicity in hyperoxia is O_2^- and its progeny. The enzymatic defence against O_2^- is superoxide dismutase (SOD)[41–43]. In fact, SOD was contingent for the evolution of early aerobic organisms[41]. In the prokaryotes, SOD is induced in hyperoxia. Exposure of *E. coli* and *S. faecalis* to 25 atm oxygen elicits induction of SOD synthesis 16–25 times, which correlates acquisition of tolerance towards hyperoxia[41]. However, SOD levels of amphibian tissues did not increase over that of fishes[14]. Instead, there was a burst of LGO activity in those successful amphibians[26,27], that survived the hyperoxia through the late Carboniferous and early Permian. The successful tetrapods started synthesizing high amounts of ascorbic acid apparently to protect the tissues against oxidative damage. In the phylogenetic evolution, the biosynthetic capacity continued in the reptiles, most of the mammals and birds.

Subclinical deficiency

Lack of ascorbic acid causes scurvy. So it would appear that if there is no scurvy there is no lack of ascorbic acid. However, scurvy is not a first symptom of lack but a final collapse, a premortal syndrome, and there is a very wide gap between scurvy and full health[44]. Although frank scurvy is rare nowadays, a more incidious condition – the subclinical ascorbic acid deficiency – is common in many parts of the world, particularly involving the nursing mother, infant and elderly. Subclinical deficiency, or marginal ascorbic acid deficiency as it may be called, relates to a state of low tissue level of ascorbic acid, which might cause incipient biochemical changes without showing any apparent clinical symptom. We have recently observed[5,45] that in marginal ascorbic acid deficiency in the guinea pig, oxidative damages such as lipid peroxidation and protein oxidation occur progressively in almost all tissues including liver, lung, heart, kidney, adrenal glands and testes. The oxidative damage occurs despite the presence of adequate levels of other antioxidants like α-tocopherol, glutathione, protein thiols and scavenging enzymes, namely SOD, catalase and glutathione peroxidase[5,45]. Lipid peroxidation and protein changes disappear after ascorbic acid therapy. We have taken the guinea pig as a model animal, because like humans it cannot synthesize ascorbic acid, so the results may be applicable to humans. Particular mention should be made about heart tissue[5]. The levels of antioxidants and free radical scavenging enzymes are normally low in the heart. We have indicated[5] that chronic subclinical ascorbic acid deficiency may produce progressive oxidative damage which in the long run may lead to permanent degenerative vascular diseases and myocardial infarction.

Protection of microsomal membranes against lipid peroxidation and oxidative damage of proteins

Numerous studies[2,46] have been made *in vitro* for elucidating the mechanism of oxidative damage and its prevention. However, most of these studies require the presence of free iron in the incubation medium, a condition which has apparently no relevance to the *in vivo* situation. This is because in the normal physiological condition, iron does not exist in the free state but remains tightly bound with proteins. Using a model *in vitro* system, which is more relevant to the *in vivo* situation, we have demonstrated[47,48] that NADPH initiates lipid peroxidation and oxidative degradation of microsomal proteins in the absence of free iron. Lipid peroxidation and protein

degradation are mediated by cytochrome P450 and specifically prevented by ascorbic acid. Other scavengers of ROS including SOD, catalse, GSH, vitamin E are ineffective. Ascorbate also prevents $O_2^{\cdot-}$-initiated free iron-independent P450-mediated protein oxidation. Probably the oxidant is a perferryl moiety, namely, P450 $Fe^{3+}\cdot O_2^{\cdot-}$. The oxidative degradation of proteins occurs irrespective of tissues, namely liver, kidney, lung, heart, adrenal gland and brain[47,48]. It is a two-step process: (i) $P450Fe^{3+}\cdot O_2^{\cdot-}$-mediated oxidation of proteins and (ii) rapid proteolytic degradation of the oxidized proteins. Using lysyl residue as a model, a mechanism has been proposed[47] for $P450Fe^{3+}\cdot O_2^{\cdot-}$-mediated protein oxidation as indicated below.

$$RCH_2NH_2 + P450Fe^{3+}\cdot O_2^{\cdot-} + H^+ \rightarrow \dot{R}CHNH_2 + P450Fe^{3+} + H_2O_2$$

$$\dot{R}CHNH_2 \rightarrow RCH{=}NH$$

$$RCH{=}NH + H_2O \rightarrow RCHO + NH_3 .$$

Apparently, $P450Fe^{3+}\cdot O_2^{\cdot-}$ abstracts a hydrogen from the side chain amino acid residue producing a carbon-centred radical followed by its conversion to an imino derivative, which then undergoes spontaneous hydrolysis producing an aldehyde derivative of the lysyl residue. Ascorbic acid specifically prevents initiation of protein oxidation by providing an easily donatable hydrogen for abstraction by $P450Fe^{3+}\cdot O_2^{\cdot-}$, thus sparing the side-chain amino acid residue as shown below:

$$P450Fe^{3+}\cdot O_2^{\cdot-} + AH_2 \rightarrow P450Fe^{3+}\cdot O_2^{=} + AH^{\cdot} + H^+$$

$$AH^{\cdot} + AH^{\cdot} \rightarrow AH_2 + A.$$

In this process, ascorbate (AH_2) is oxidized to ascorbate-free radical ($AH^{\cdot}$), which apparently decays by disproportionation to AH_2 and dehydroascorbate (A). Once ascorbic acid intercepts the reaction between $P450Fe^{3+}\cdot O_2^{\cdot-}$ and the side chain amino acid residue, the oxidation of the protein is prevented. So, the subsequent proteolytic degradation of the protein is also prevented.

Protection of collagen against oxidative damage

We have also shown that ascorbic acid prevents oxidative degradation of collagen by ROS produced by $O_2^{\cdot-}$ generated from activated macrophages[49]. The extracellular matrix of mammals contains numerous macrophages that undergo oxidative burst during phagocytosis and release in the environment large amounts of $O_2^{\cdot-}$, redox proteins, like cytochrome b_{558} as well as metalloproteinases. As mentioned above, in the case of microsomal cytochrome P450, collagen is apparently oxidized by a ferryl type of ROS produced from $O_2^{\cdot-}$ and cytochrome b_{558}. The oxidized collagen subsequently undergoes proteolytic degradation by the metalloproteases. Exposure of collagen fibrils to $O_2^{\cdot-}$ generated by the xanthine–xanthine oxidase system also results in rapid oxidation of collagen[49]. In this case, the collagen oxidation is a function of the protein-bound redox iron of xanthine oxidase (XOD). The reactive oxygen species involved is also probably a ferryl moiety, namely, $XOD\text{-}Fe^{3+}\cdot O_2^{\cdot-}$. As observed in the case of microsomal proteins, ascorbic acid apparently prevents collagen oxidation by interacting with the perferryl moiety. Once collagen oxidation is prevented, the subsequent proteolytic degradation of collagen is also prevented. SOD also prevents $O_2^{\cdot-}$-induced collagen breakdown, but in contrast to ascorbic acid which is ubiquitous *in vivo*, the content of SOD in the extracellular fluid is negligible[50,51]. This imparts a specific important role of ascorbic acid for the protection of collagen in the extracellular matrix of mammalian tissues. We consider that an apparently specific function of ascorbic acid is to protect the collagen of the extracellular matrix from oxidative degradation.

Conclusion

The above mentioned results indicate that a potential and apparently specific role of ascorbic acid is to protect the mammalian tissues against oxidative damage both at the intracellular and extracellular levels. We have reported that even in subclinical ascorbic acid deficiency, oxidative damage occurs as evidenced by lipid peroxidation and damage of microsomal proteins[5,45] and that persistent subclinical deficiency results in progressive oxidative damage. We postulate that scurvy symptoms in acute ascorbic acid deficiency is apparently a premortal syndrome of severe oxidative damage, leading to disintegration of tissues. In our present day lifestyle, we are continuously exposed to environmental pollutants such as cigarette smoke, drugs, pesticides, xenobiotics and car exhausts. These pollutants result in increased production of reactive oxygen species, leading to increased oxidative damage such as lipid peroxidation and oxidative degradation of proteins. Since oxidative damage is supposed to be a physiological event associated with various degenerative diseases and aging, we postulate that vitamin C is probably a potential saviour against aging and degenerative diseases.

RESEARCH ARTICLE

Effect of transient increase in greenhouse gases and sulphate aerosols on monsoon climate

M. Lal*, U. Cubasch, R. Voss and J. Waszkewitz

Deutsches Klimarechenzentrum GmbH, D-20146 Hamburg, Germany
*Permanent address: Centre for Atmospheric Sciences, Indian Institute of Technology, New Delhi 110 016, India

The response to transient increase of greenhouse gases and sulphate aerosols in the Earth's atmosphere on the monsoon climate is examined using the data generated in coupled atmosphere–ocean model experiments performed recently at Deutsches Klimarechenzentrum, Germany. We discuss here the potential role of the sulphate aerosols in obscuring the greenhouse gas-induced warming over the Indian subcontinent during the past century. A comparison of observed and model-simulated trends in annual mean near-surface temperature and monsoon rainfall over the region provides ample evidence of the model's skill. The combined greenhouse gas and sulphate aerosol forcing experiment replicates the observed changes over the region in a broad sense both during winter and on annual mean basis. The year-to-year variability in simulated monsoon rainfall over the Indian subcontinent is in fair agreement with the observed climatology.

We present here a plausible scenario of climate change for the Indian subcontinent as expected by the middle of next century taking into account the projected emission of greenhouse gases and sulphate aerosols. The results suggest an increase in annual mean surface air temperature of 1.0°C over the land regions of the Indian subcontinent in the decade 2040s with respect to the 1980s. During the monsoon season, this warming is found to be less pronounced than in the winter months over the region. Moreover, the warming of land region of the Indian subcontinent is likely to be relatively lower in magnitude as compared to the adjoining ocean, resulting in a decline in land–sea thermal contrast, the primary factor responsible for onset of summer monsoon circulation. As a consequence and contrary to simulations which consider only CO_2 forcing, a weakening of pressure gradient over the region and a decline in monsoon rainfall is simulated by the model.

ANY changes in the radiative balance of the Earth, including those due to anthropogenic increase in greenhouse gases or in aerosols, tend to alter atmospheric temperature and the associated circulation and weather patterns. During the past two decades, several studies have been undertaken to assess the effect of increasing greenhouse gases on the Earth's climate through the use of numerical models[1–8]. The numerical experiments performed earlier in this decade with the state-of-art coupled ocean–atmosphere general circulation models (GCMs) estimated that the increase in greenhouse gases in the atmosphere since the industrial revolution should have generated an increase in global temperature of about 0.6–1.3°C (ref. 9). In reality, the global mean temperatures have risen by about 0.45 ± 0.15°C (ref. 10) which is at the lower end of uncertainty of the response of Earth's climate to greenhouse gases. These experiments predicted a mean rate of global warming of about 0.3°C/decade during the next century as a result of increasing greenhouse gases in the atmosphere[9]. Considerable variability in the rate of warming in different parts of the globe was also suggested.

The most recent IPCC Report[11] has identified sulphate aerosols as a secondary, but potentially important, component that can also affect the climate system by changing the radiative balance of the atmosphere. Sulphate aerosols interact mainly with solar radiation and enhance the Earth's albedo, thereby cooling the surface temperature[12]. In a numerical experiment with an atmospheric GCM coupled to slab ocean using the observed greenhouse forcing over the past 100 years and an estimate of the trend in sulphate aerosol burden calculated by an off-line chemical model, Roeckner *et al.*[13] reported a net cooling over the highly industrialized regions of the northern hemisphere such as eastern United States and large parts of Eurasia. Recent applications of coupled ocean–atmosphere climate models[14,15] have confirmed that, while the combined effect of greenhouse gases and sulphate aerosols is to marginally reduce the mean rate of global warming (0.2°C/decade which is still twice the rate of the tolerance limit of some of the sensitive ecosystems) and that the global warming will accelerate as greenhouse gas forcing begins to dominate the aerosol forcing in coming years, anthropogenic sulphate and biomass combustion aerosols in the troposphere may lead to strong negative forcing in some regions of the globe.

Theoretically, sulphate aerosols are not the only particles that can contribute to cooling. Several kinds of natural aerosols exist in the Earth's atmosphere. They do not, however, seem to be major factors causing change. Natural aerosols – mostly continental dust, sea salt and marine sulphate compounds – have probably

remained constant in their concentration, distribution and properties for at least a century. Thus, they would not have contributed to any observable alterations in climate. The cooling trends precipitated by the major volcanic aerosols, e.g. Krakatoa in 1883 and Pinatubo in 1991 lasted only a few years. In stark contrast, sulphate aerosol compounds in the atmosphere have increased dramatically, primarily during the course of industrialization and most rapidly since about 1950 (refs. 16, 17). Climatologists have thus far focused much of their attention on industrial sulphur compounds as they are the best understood aerosols in view of the large body of data gathered in the past few decades in studies of acid rain. The sulphate aerosols are concentrated over and downwind of the main industrial regions where the present day rate of cooling is found much stronger than the global average and hence locally they may nearly cancel the warming from anthropogenic greenhouse gases. As the anthropogenically induced sulphate aerosol burden in the troposphere would have large spatial and temporal variations in the atmosphere[18], its future impact on regional scales could be in striking contrast to the impact from greenhouse gases for which the concentration changes, in most cases, are likely to be uniform throughout the globe.

Lal *et al.*[19] examined the effect of increasing anthropogenic greenhouse gases (*Business-as-usual* scenario of the Intergovernmental Panel on Climate Change[20]) on monsoon climate using the transient experiments performed with Hamburg coupled atmosphere–ocean (ECHAM1 + LSG) climate model. The study suggested that the mean surface temperature over the Indian subcontinent could significantly rise by $\geq 2°C$ in the next 100 years. An increase in monsoon rainfall over the central plains of India was also suggested. With a view to critically examining the anthropogenic influences on the observed changes in global and hemispheric near-surface temperatures during the past several decades and on the future climate, a set of three new long-term (1880–2049) transient simulations have been performed recently at Deutsches Klimarechenzentrum, Germany[15,21], the first being the control simulation with constant radiative forcings, the second one with observed (for the past century) and projected greenhouse gas-induced radiative forcings and the third with combined observed and projected greenhouse gas and sulphate aerosol forcings. The seasonally and annually averaged spatial patterns of near-surface temperature and precipitation changes are found to be quite different in the experiment with combined greenhouse gas and sulphate aerosol forcings than in the experiment with greenhouse gas forcing alone specially in the northern hemisphere and over Eurasia in particular[21]. In view of this, we have analysed the data generated in these recent climate simulations for a re-assessment of the anticipated climate change over the Indian subcontinent.

In this article, we compare the observed and model-simulated trends in area-averaged annual mean near-surface temperature and monsoon rainfall over the Indian subcontinent for the period 1880–1993. A comparison of observed and model-simulated regional trends in near-surface temperature provides a potentially more stringent test of the model's credibility. An updated plausible future climate scenario for the Indian subcontinent is also presented here.

Climate model

The present study is based on analysis of data generated in numerical experiments performed with the so-called *E*uropean *C*ommunity *HAM*burg (ECHAM version 3) atmospheric model coupled to a *L*arge *S*cale *G*eostrophic ocean model (hereafter referred to as ECHAM3 + LSG model).

ECHAM3 is the third generation atmospheric general circulation model[22] used for global climate modelling investigations in Germany. The model equations are solved on 19 vertical levels in a hybrid sigma-pressure system by using the spectral transform method with triangular truncation at wavenumber 21 (T-21). Nonlinear terms and physical processes, however, are evaluated at grid points of a *Gaussian grid* providing a nominal resolution of 5.625° in latitude and longitude. The radiation scheme is based on a two-stream approximation of the radiative transfer equations with six spectral intervals in the infrared and four in the solar spectrum[23]. Gaseous absorption due to water vapour, carbon dioxide and ozone is taken into account as well as scattering and absorption due to aerosols and clouds. The cloud optical properties are parametrized in terms of the cloud water content. The parametrization of cumulus convection in ECHAM3 version of the model is based on the concept of mass flux scheme of Tiedke[24], which represents various types of convection, from the penetrative convection maintained by large-scale convergence of moisture to the shallow convection such as trade-wind cumuli associated with suppressed conditions. Stratiform clouds are predicted *per se* in accordance with a cloud water equation, including sources and sinks due to condensation/evaporation and precipitation formation. The land surface scheme[25] considers the heat and water budgets in the soil, snow cover and land and the heat budget of permanent land and sea ice. The heat transfer equation is solved in a five-layer model assuming that the heat flux vanishes in the bottom-most layer. The integration is performed following the semi-implicit scheme with leap frog time filter at every 40 min.

The LSG ocean model[26] is based on a numerical formulation of the primitive equations appropriate for large scale geostrophic motion. The nonlinear advection of momentum is neglected and fast gravity waves are

strongly damped by an implicit time integration scheme using a time step of 30 days. The discretization of the ocean model is based on 11 unequally spaced vertical levels and two overlapping 5.625° horizontal grids, which are interpolated onto the resolution of the Gaussian grid used in ECHAM3. In the coupled mode, the basic time step is reduced to 1 day for the computation of sea ice and the temperature and salinity in the two uppermost ocean layers in order to resolve the rapid response of the upper ocean to the short-term variability of the atmosphere.

The ECHAM3 and LSG are coupled by the air–sea fluxes of momentum, sensible and latent heat, short and long wave radiation and fresh water. To avoid a climate drift of the coupled system in long time integrations, a flux adjustment term is applied. Both the models are integrated synchronously but with their respective time steps.

Numerical experiments and region of interest

In the first experiment (hereafter referred to as C), the control reference atmosphere has been simulated with the coupled climate model over a 170-year period with constant atmospheric CO_2 concentration. The second experiment (hereafter referred to as G) included the radiative forcing of observed atmospheric equivalent CO_2 (CO_2 and other greenhouse gases) concentrations for the period 1880–1989 and the projected (based on *Business-as-usual* scenario of IPCC and representing a ~ 1.3% per year compound increase of CO_2) equivalent CO_2 concentrations for the period 1990–2049. In the third experiment (hereafter referred to as S), the effect of both the greenhouse gases (equivalent CO_2) as well as the sulphate aerosols was considered. The anthropogenic sulphate burden information was obtained from Langner and Rodhe's calculations[27] and the direct radiative forcing was mimicked by a change of the surface albedo following the algorithm developed by Charlson *et al.*[12]. The global mean sulphate forcing increased continuously, and more rapidly from 1950 onwards. Figure 1 depicts the spatial distribution of sulphate loading over the Indian subcontinent for the present-day atmosphere and that expected[27] by the middle of next century.

The geographic region of interest for our data analysis reported herein was mainly confined to the region bounded by ~ 5°N to 35°N latitude and ~ 65°E to 95°E (Indian subcontinent and adjoining seas). It may be recalled that the ECHAM models (both version 1 and version 3) have demonstrated[19,28,29] considerable skill in simulating the Indian monsoon circulation and the seasonal cycle of observed climatology for the region at varying resolutions. Therefore, we shall not attempt to elaborate on these general aspects here. It may however be worth mentioning here that the spatial pattern of model-simulated monsoon rainfall in the present version of the model (ECHAM3) is in better agreement

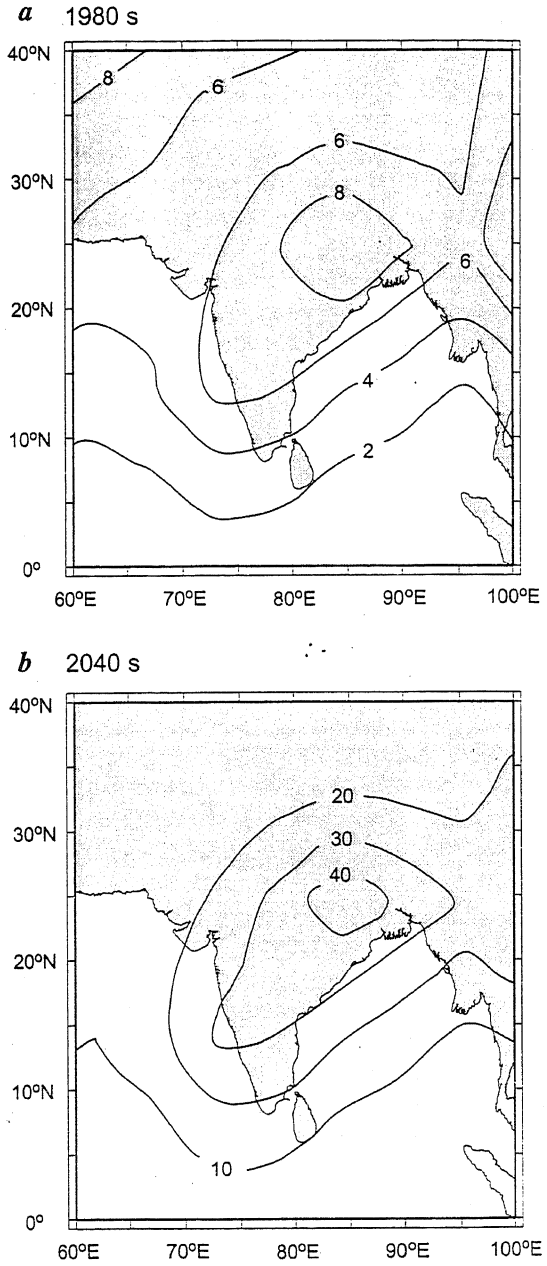

Figure 1. The spatial distribution of anthropogenic sulphate aerosol burden (mg m^{-2}) in the atmosphere over the Indian subcontinent for 1980s and 2040s (based on Langner and Rodhe's calculations[27]).

with the observed pattern (except that the observed sharp east–west gradient in rainfall over peninsular India is not precisely resolved in the model due to rather coarse resolution) than in the previous version of the model (ECHAM1) primarily as a result of inclusion of mass flux convergence scheme.

Comparison of past observed and simulated trends in regional climatology

In order to place a high degree of confidence in future climate change, climate models must replicate the past

trends in key climate elements within the limits of natural variability. Analysis of the recent simulated global and northern hemispheric mean near-surface temperatures has proved[15] that an anthropogenic climate change signal in observed records of near-surface air temperature change can be detected at 95% confidence level. Figure 2 depicts the global 5-year running mean surface air temperatures as observed[30] for the period from 1880 to the present and as simulated by the model for the period 1880–2049 in experiments G and S. An increasing trend in both the observed and the model-simulated annual mean near-surface temperatures is seen in the recent decade but is more rapid in experiment G than either in experiment S or observations. This suggests that model-simulated past trend in global mean surface warming can be reconciled with the observed warming trends only when the cooling effect of aerosols on climate is accounted for.

On regional scales, the higher level of year-to-year variability obscures any systematic differences in surface temperature simulated in experiments G and S in the first half of this century. Figure 3 depicts the 5-year running mean anomalies in area-averaged mean surface air temperatures as observed[31] for the period from 1880 to the present and as simulated by the model for the period 1880–2049 in experiments G and S for the Indian subcontinent (land points only). The temperature anomalies in experiment G show a much higher increasing trend than observed after the year 1970. The temperature anomalies in experiment S do not exhibit any increasing trend until after 1985. The inter-annual variability generated by the model is quite realistic in a statistical sense if we recognize that these climate model simulations do not attempt to precisely simulate individual years.

Table 1 gives the mean annual and seasonal (winter and monsoon) changes in area-averaged near-surface temperature in the decade 1980–89 with respect to the decade 1880–89 over the Indian subcontinent as observed[32] and those simulated in the experiments G and S. It may be noted here that the simulated area-averaged (land only) annual mean temperatures over the Indian subcontinent for the three decades (1931–1960) are 21.7, 21.8 and 21.7°C in experiments C, G and S respectively as compared to the observed[33] climatology of 21.6°C, suggesting that the annual mean near-surface temperature climatology simulated by the model in all the three experiments is quite close to that observed over the region.

Two important points emerge from Table 1. The first is that the annual mean temperature change simulated by the model in the greenhouse gas forcing only experiment is a factor of two higher than the observed changes over the past century over the Indian subcontinent. The combined greenhouse gas and sulphate aerosol forcing experiment is able to replicate the observed changes over the region in a broad sense both during the winter and on annual mean basis. The second point is that the influence of clouds may be more dominant over the region during the monsoon season as evidenced from the observed cooling. An area-averaged change in fractional cloud cover of + 0.3% and – 0.8% is obtained

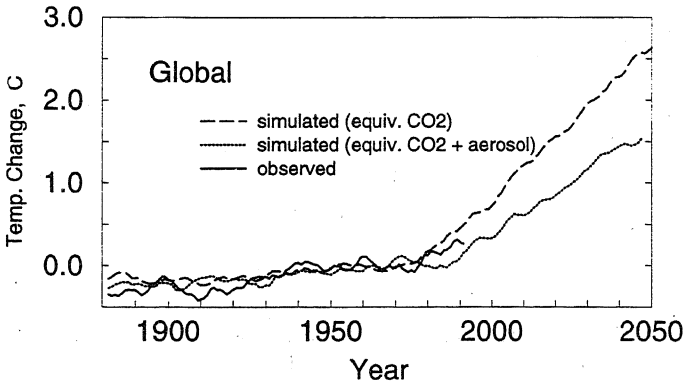

Figure 2. Observed (1880–1992) and model-simulated (1880–2049) trends in global mean surface air temperature anomalies (5-year running means).

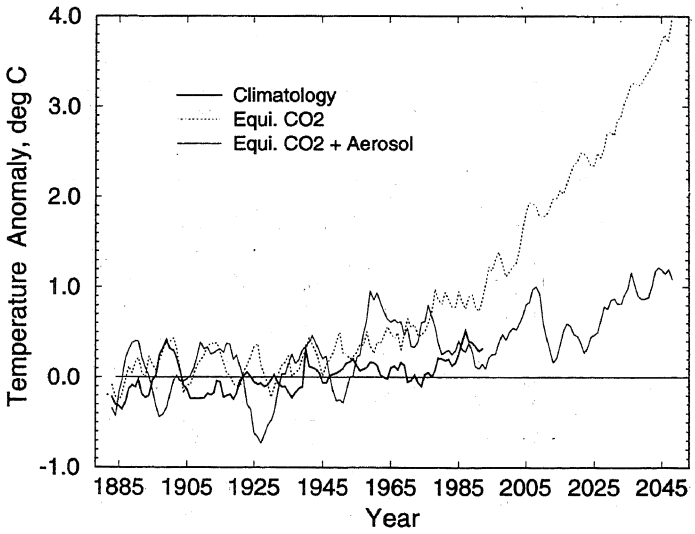

Figure 3. Observed (1880–1993) and model-simulated (1880–2049) trends in area-averaged annual surface air temperature anomalies (5-year running means, land regions only) over the Indian subcontinent.

Table 1. Observed and model-simulated changes in area-averaged near-surface temperature in the decade 1980–89 with respect to the decade 1880–89 over the Indian subcontinent

Period	Experiment G (Land only)	Experiment S (Land only)	Observed
Annual	0.89	0.33	0.4
Winter (DJF)	1.21	0.56	0.7
Monsoon (JJAS)	0.64	0.18	–0.3

in experiments G and S respectively in the decade 1980–89 with respect to the control climate of 1880–89 during the monsoon season over the land regions of the Indian subcontinent. The precise modulating role of clouds in numerical models is not yet fully understood.

The spatial distribution of changes in annual mean near-surface temperature over the Indian subcontinent as simulated in experiments G and S for the decade 1980–89 with respect to the control climate of decade 1880–89 is illustrated in Figure 4. While an increase in annual mean near-surface temperature is simulated everywhere over the Indian subcontinent in experiment G, a decrease in near-surface temperature over the subcontinent to the north of 25°N is simulated in experiment S. While analysing the decadal trends in observed surface air temperature over India, Srivastava *et al.*[34] have clearly demonstrated a decreasing trend in almost all of the northern part of the country (north of 23°N) and a rising trend elsewhere. The simulated cooling over the north and northwest India in experiment S is thus in conformity with the earlier observations[34], indicating that the combined CO_2 and aerosol forcing in the model simulation is able to faithfully reproduce the changes in near-surface temperature over the region as observed during the past century. The simulated warming over the region in experiment G during the past century is much larger than that has occurred in reality. It is interesting to note here that, even though the regionally confined forcing resulting from anthropogenic sulphur emissions has increased relatively sharply only since 1950, its response to the surface temperature change is most pronounced in tropics in a coupled atmosphere–ocean system, in agreement with the current view among scientific community[35]. This suggests that the realized climate change over the region during the past century can, to a large extent, be attributed to the combined greenhouse gas and sulphate emissions.

Figure 5 depicts the 10-year running mean anomalies in area-averaged mean rainfall as observed[36–38] for the period from 1880 to the present and as simulated by the model for the period 1880–2049 in experiments G and S over the Indian subcontinent. The inter-annual

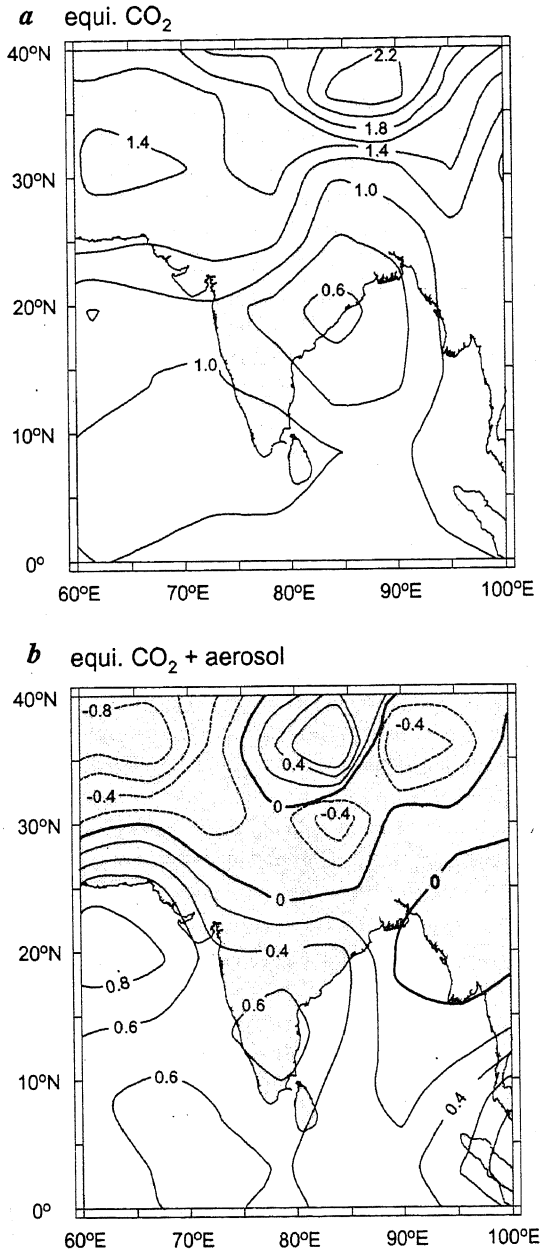

Figure 4. Spatial distribution of change in annual mean surface air temperature (°C) during the decade 1980s with respect to the decade 1880s over the Indian subcontinent as simulated by the model due to (*a*) equivalent CO_2 forcing and (*b*) combined equivalent CO_2 and aerosol forcings.

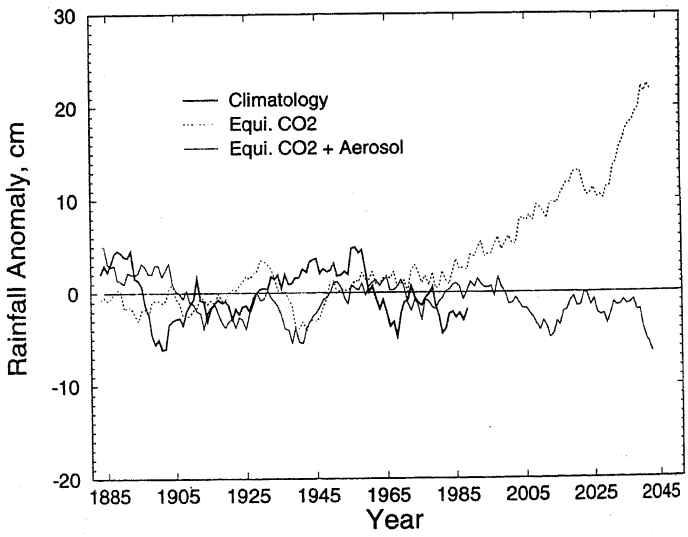

Figure 5. Observed (1880–1993) and model-simulated (1880–2049) trends in area-averaged monsoon rainfall anomalies (10-year running means, land regions only) over the Indian subcontinent.

variability in simulated monsoon rainfall over the Indian subcontinent is in fair agreement with the observed climatology. The simulated rainfall anomalies in the experiment G show an increasing trend after the year 1970. This increasing trend is not discernible in either the observed anomalies or in the experiment S until the present-day.

In the available observed records of rainfall over the Indian subcontinent, a 30-year cyclicity has been reported[32], with no definite trend over the past century. However, as noted in Santer *et al.*[39], while the simulated temperature in a low resolution model on regional scales has a high signal-to-noise ratio, the simulated rainfall is quite noisy and it is difficult to identify any clear increasing/decreasing trends or cyclicity in the simulated rainfall during the past few decades.

The spatial distributions of model-simulated changes in monsoon rainfall over the region in experiments G and S in the decade 1980s with respect to 1880s are depicted in Figure 6. While an increase in excess of 0.5 mm day^{-1} in the past century is simulated in experiment G over the semi-arid regions of north India, both the model simulation in experiment S and the observed records[40] suggest an enhancement in aridity over this region. However, the simulated changes in rainfall over the Indian subcontinent ($\pm$ 1 mm day^{-1}) in both the experiments G and S during the past century are within the range of inter-annual variability observed over the region.

In addition to that discussed above, the ECHAM3 + LSG model has been able to reproduce the observed seasonal reversal in mean sea level pressure, the location of heat low and the other characteristic features of the monsoon circulation over the region considered here in its control simulation. A fair degree of confidence can, therefore, be placed in the projected climate change scenario simulated by the model in experiment S.

Future projections on regional climate change

The time evolution of future changes in globally averaged annual mean surface temperature as simulated in transient experiments G and S is depicted in Figure 2. The model-simulated globally averaged annual mean warming by the decade 2040s with respect to the decade 1980s of 2.48°C in experiment G (with greenhouse gas forcing only) approximates a 0.35°C/decade rate of warming, in overall agreement with the IPCC[20] projection of 0.3°C/decade made for *Business-as-usual* scenario with a simplified upwelling-diffusion model of Wigley and Raper[41]. The globally averaged annual mean warming by the decade 2040s with respect to the decade 1980s simulated by the model in experiment S (combined greenhouse gas and sulphate aerosol forcings) is 1.62°C. This gives a warming rate of 0.23°C/decade over the next century, though lower than with only greenhouse gas forcing but still greater than that observed over the past 10,000 years. The model-simulated rise in globally averaged surface air temperatures during December–February and June–August in the experiments G and S is given in Table 2. It is evident that in both the experiments, the warming is more pronounced during NH winter than in NH summer and over land regions which is typical of all previous modelling results and is physically plausible[9].

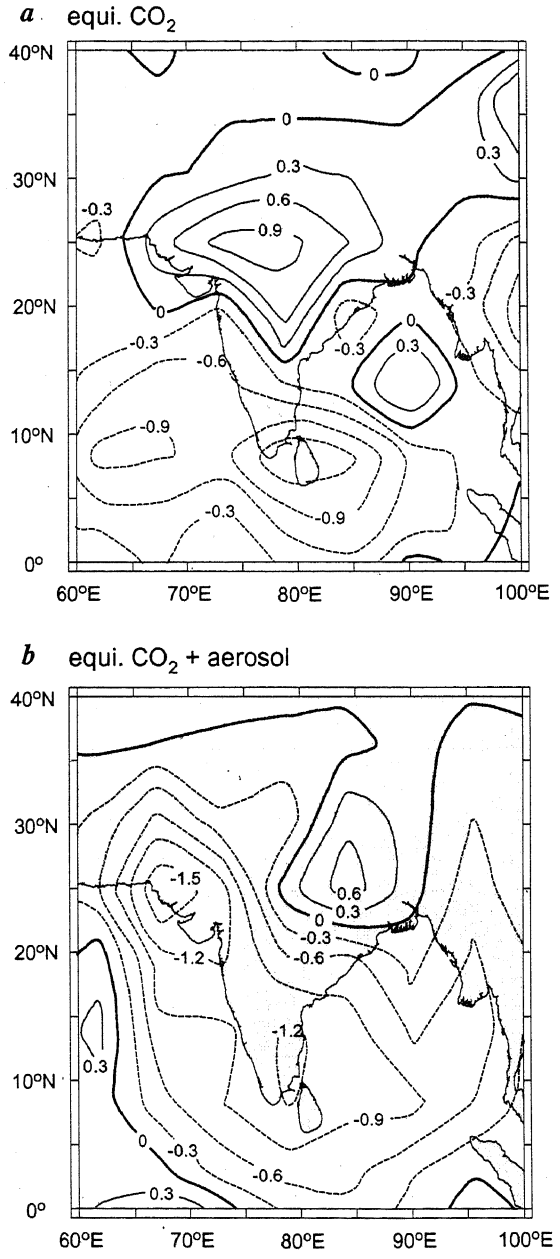

Figure 6. Spatial distribution of change in monsoon rainfall (mm day^{-1}) during the decade 1980s with respect to the decade 1880s over the Indian subcontinent as simulated by the model due to (*a*) equivalent CO_2 forcing and (*b*) combined equivalent CO_2 and aerosol forcings.

The development of useful estimates of future regional scale changes simulated by the global climate model is dependent upon the reliability in simulation of the large-scale circulation features and on the skill of the model in simulating the regional scale past and present-day climatology. The results on the past and present-day climate simulations with ECHAM3 + LSG climate model as discussed above provide reasonable confidence in both these aspects.

The changes in area-averaged annual and seasonal mean 2 m temperature over the Indian subcontinent as simulated by the model in experiments G and S for the period 2040s with respect to 1980s are listed in Table 3. It is seen from this table that while the simulated future warming over the region for experiment G is consistent with other model results[42,43], the warming in experiment S is lower by more than a factor two over the land regions on annual mean basis. Nonetheless, annual mean surface warming over the Indian subcontinent is only marginally lower than that simulated for the globe in spite of increasingly strong negative forcing over the region due to sulphate aerosols.

Another interesting point to note is that while the simulated surface warming is more pronounced over the land region in experiment G (greenhouse forcing only), the land region of the study area is less warm than the adjoining oceanic region in experiment S, more significantly during the monsoon season. This could imply a large-scale change in land–sea thermal contrast that determines relative summer monsoon strength over the region. We shall discuss further on this aspect later.

Table 2. Globally averaged annual and seasonal changes in 2 m temperature as simulated by the ECHAM3 + LSG climate model in G and S experiments

		Equi. CO_2		Equi. CO_2 + aerosol	
Period		2040s–1880s	2040s–1980s	2040s–1880s	2040s–1980s
Land + sea	Annual	2.76	2.48	1.90	1.62
	Winter (DJF)	2.83	2.56	2.00	1.73
	Summer (JJA)	2.72	2.44	1.82	1.54
Land only	Annual	3.61	3.41	2.15	1.95
	Winter (DJF)	3.81	3.55	2.48	2.21
	Summer (JJA)	3.57	3.46	1.93	1.82

Table 3. Model-simulated changes in area-averaged annual and seasonal mean 2 m temperature over the Indian subcontinent for the period 2040s with respect to 1980s in G and S experiments

	Equi. CO_2		Equi. CO_2 + aerosol	
Period	Land + sea	Land	Land + sea	Land
Annual	2.60	2.87	1.41	1.13
Winter (DJF)	2.79	3.16	1.63	1.68
Monsoon (JJAS)	1.87	1.88	1.38	1.05

The spatial distributions of changes in annual mean near-surface temperature over the Indian subcontinent as simulated in experiments G and S for the decade 2040–49 with respect to the present-day climate are illustrated in Figure 7. The simulated surface warming over the region in experiment G during the decade 2040s is ≥ 2°C over most part of the subcontinent, consistent with our findings reported earlier[19]. In experiment S, the magnitude of simulated surface warming

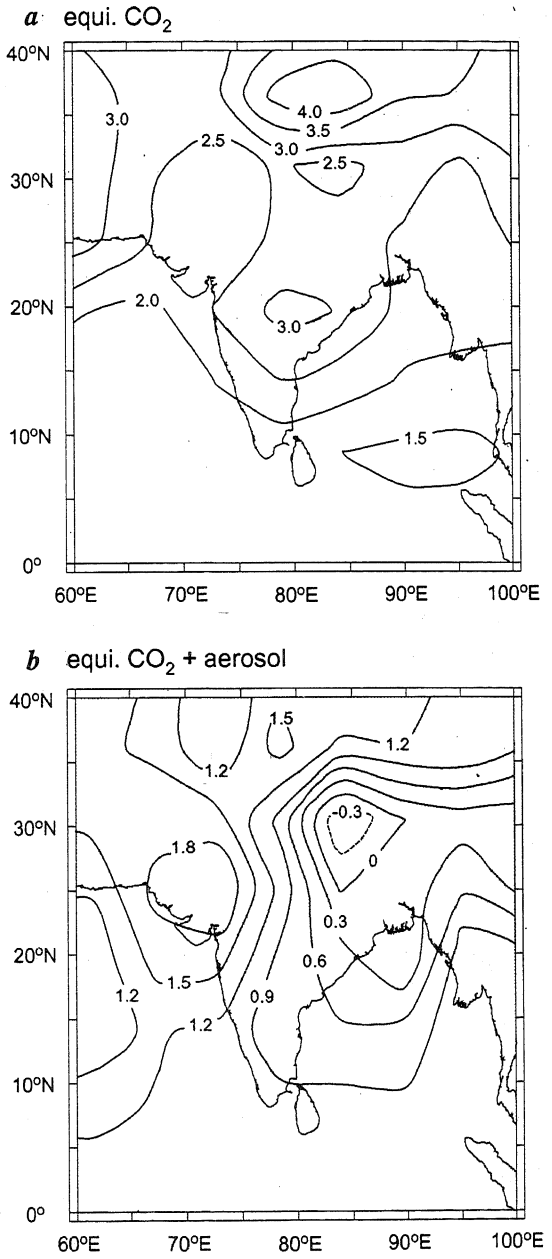

Figure 7. Spatial distribution of change in annual mean surface air temperature (°C) during the decade 2040s with respect to the decade 1980s over the Indian subcontinent as simulated by the model due to (*a*) equivalent CO_2 forcing and (*b*) combined equivalent CO_2 and aerosol forcings.

over most of the region (with the exception of western India) is considerably low (< 1.0°C). A marginal cooling is also simulated in isolated region over the central plains of India.

Figure 8 depicts the spatial distribution of seasonal mean near-surface temperature over the Indian subcontinent as simulated in experiment S for the decade 2040–49 with respect to the present-day climate. During winter, while north and north-west India may experience > 2.0°C warming, cooling of over 2.0°C is simulated by the model over the north-east India. The warming simulated by the model over most of the study area during monsoon season is 1.0°C or less. The surface cooling confined to central India is simulated to be close to 0.5°C during this season.

On global mean basis, the simulated increase in rainfall for the decade 2040s is close to 0.2 mm day^{-1} both during winter and summer in experiment G. This increase is reduced by a factor of two to 0.1 mm day^{-1} during winter and by a factor of four to 0.05 mm day^{-1} during

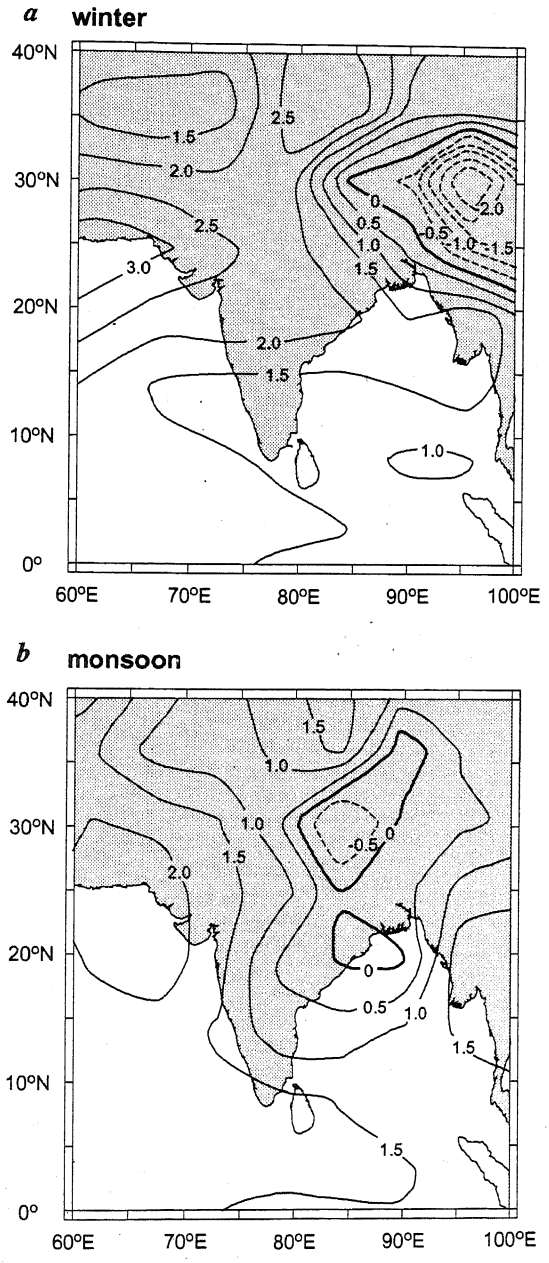

Figure 8. Spatial distribution of model-simulated changes in (*a*) winter and (*b*) monsoon surface air temperature (°C) during the decade 2040s with respect to the decade 1980s over the Indian subcontinent due to combined equivalent CO_2 and aerosol forcings.

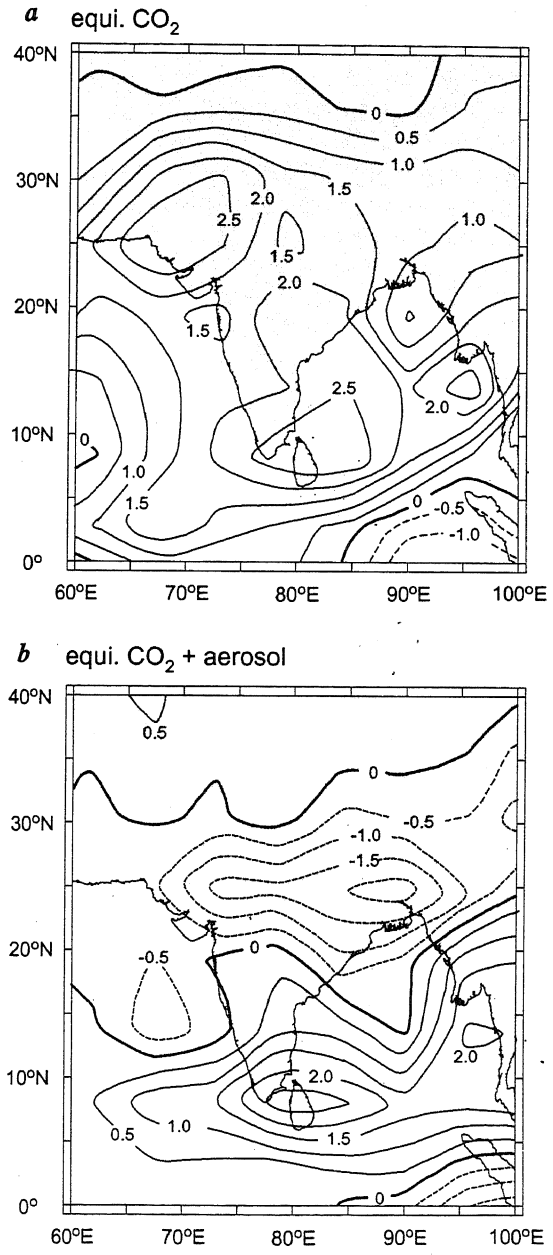

Figure 9. Spatial distribution of change in monsoon rainfall (mm day^{-1}) during the decade 2040s with respect to the decade 1980s over the Indian subcontinent as simulated by the model due to (*a*) equivalent CO_2 forcing and (*b*) combined equivalent CO_2 and aerosol forcings.

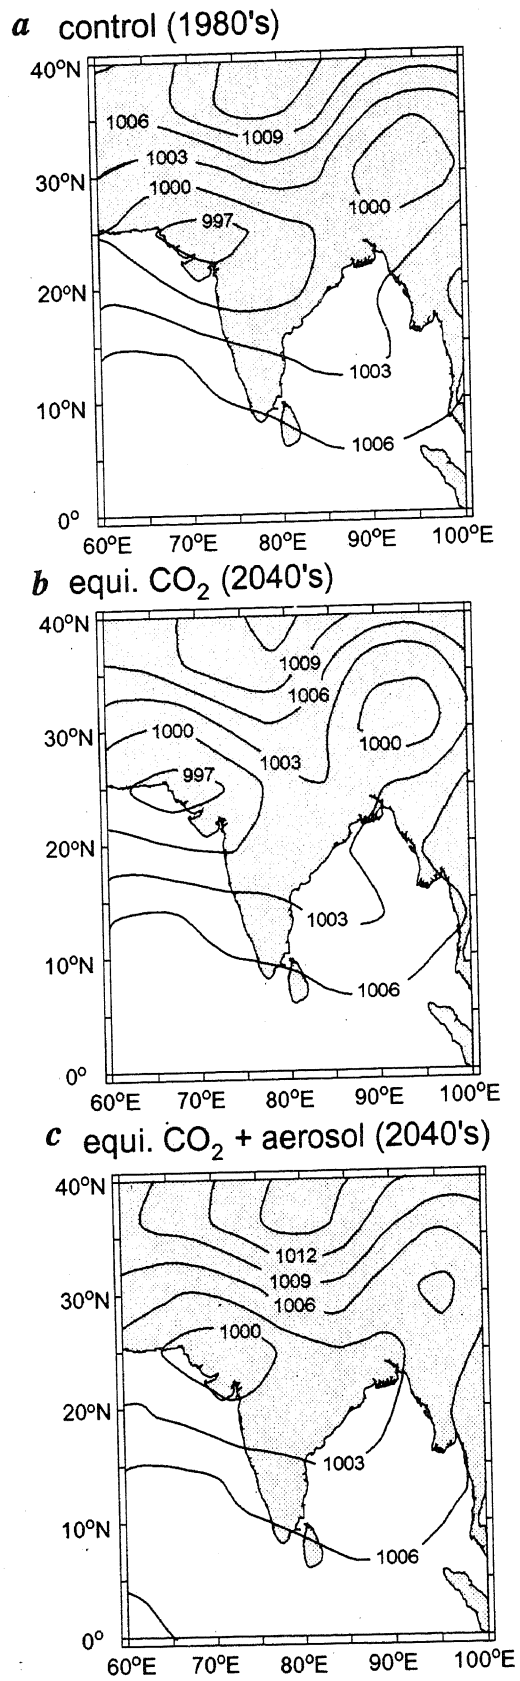

Figure 10. Spatial distribution of model-simulated mean sea level pressure (hPa) over the Indian subcontinent in the month of July during (*a*) 1980s in control experiment, (*b*) 2040s in equivalent CO_2 forcing experiment and (*c*) 2040s in combined equivalent CO_2 and aerosol forcings experiment.

summer in experiment S. While no significant increase in winter precipitation is simulated over the Indian subcontinent, for the decade 2040s, the model simulates an increase in summer monsoon rainfall by about 2 mm day^{-1} in experiment G. The increase in summer monsoon rainfall simulated by the model in experiment G (Figure 5) is consistent with findings from other model simulations[42,43] in enhanced greenhouse gas forcing-only experiments. In experiment S (combined greenhouse gas and aerosol forcings), however, a decrease of about 0.5 mm day^{-1} in summer monsoon rainfall is simulated for the decade 2040s.

The spatial distribution of model-simulated changes in monsoon rainfall over the region in experiments G and S for the decade 2040s with respect to 1980s is depicted in Figure 9. While an increase in excess of 2.5 mm day^{-1} of rainfall is simulated in experiment G over the semi-arid regions of north India with over 1.0 mm day^{-1} elsewhere in the region, the simulated decrease in rainfall over the entire central plains of the Indian subcontinent in experiment S is larger than 1.0 mm day^{-1}. The simulated decline in summer monsoon rainfall over the region in experiment S is found to be marginally above the range of inter-annual variability observed over the region for the present-day atmosphere.

As noted earlier, the simulated increase in surface temperature over the oceanic region of the study area is higher than the land mass of the Indian subcontinent, particularly during the monsoon season in model experiment with combined greenhouse gas and aerosol forcings. This should lead to a reduction in land–sea

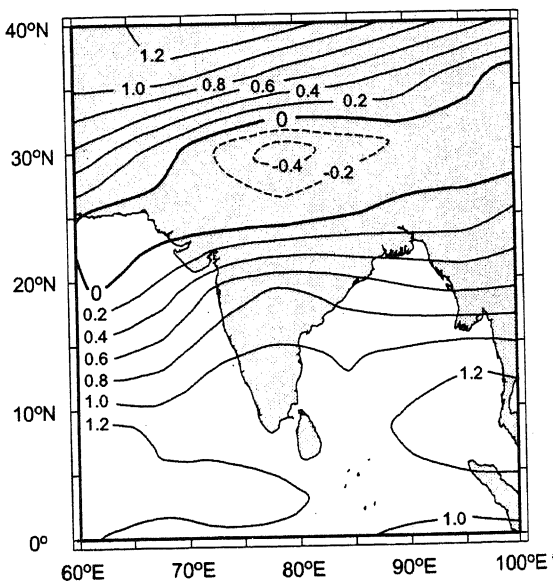

Figure 11. Spatial distribution of change in specific humidity (g/kg) in monsoon season at 850 hPa level during the decade 2040s with respect to the decade 1980s over the Indian subcontinent as simulated by the model in combined equivalent CO_2 and aerosol forcings experiment.

thermal contrast. As a consequence, we expect that the monsoon trough and the heat flow over the north-west India during the monsoon season should weaken. Figure 10 illustrates the spatial distribution of mean sea level pressure in July over the Indian subcontinent for the decades 1980s (in experiment C), and 2040s (in experiments G and S). It is clearly seen that, while the mean sea level pressure distribution over the Indian subcontinent has remained unchanged in experiment G, the low pressure over northwest India has weakened in experiment S. It may be recalled that much of the monsoon rainfall over the central plains of India is associated with the low pressure vortices which develop over the north Bay of Bengal and move on to the subcontinent along the monsoon trough in a northwesterly direction. As a consequence of weaker pressure gradient (and hence an ill-defined monsoon trough), the monsoon circulation simulated in the experiment S is not likely to be as vigorous as simulated in experiment G, leading to lesser moisture convergence over the land regions. A weakening of the low level zonal flow in the decade 2040s relative to decade 1980s is simulated by the model in experiment S over south peninsular India during the monsoon season. The spatial distribution of simulated change in 850 hPa specific humidity during the monsoon season over the Indian subcontinent in the decade 2040s in experiment S (Figure 11) suggests a decline in water vapour content of the atmosphere over the central plains of India. The area averaged simulated change in specific humidity in July over the study region between surface and 500 hPa level is lower by a factor two in experiment S relative to experiment G in the decade 2040s. The relatively less evaporation from the land surface, which is comparatively cooler than in enhanced greenhouse gas forcing only experiment, also reduces water vapour content of the atmosphere, thus resulting in a decline in summer cloud cover (Figure 12) and associated monsoon rainfall over the central plains of India.

An analysis of the area-averaged (land points only) daily rainfall from May to October simulated by the model in experiment C (averaged for the decade 1980s) and experiments G and S (averaged for the decade

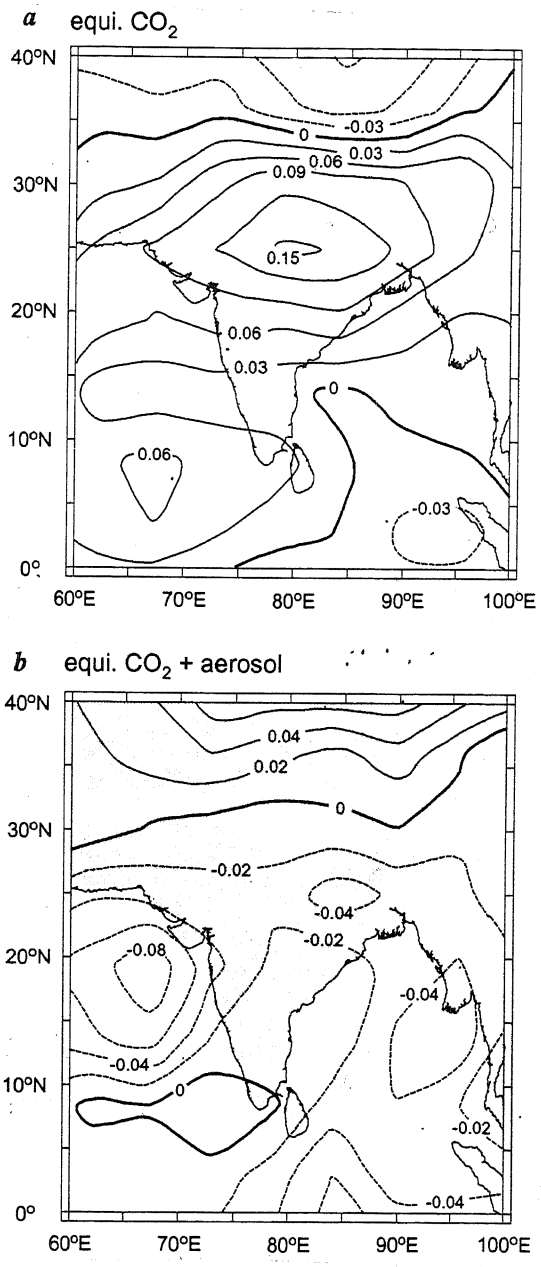

Figure 12. Spatial distribution of change in mean monsoon cloud cover (in fraction) during the decade 2040s with respect to the decade 1980s over the Indian subcontinent as simulated by the model due to (*a*) equivalent CO_2 forcing and (*b*) combined equivalent CO_2 and aerosol forcings.

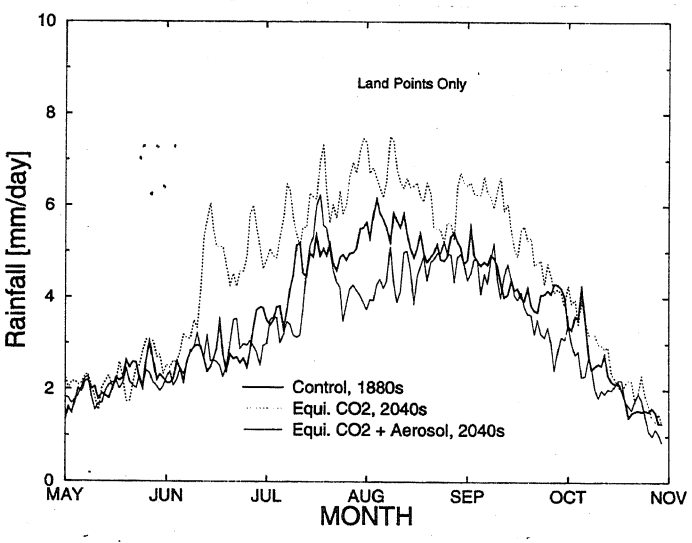

Figure 13. Time evolution of area-averaged (land points only) daily rainfall over the Indian subcontinent during the period May–October in experiment C (1980s) and in experiments G and S (2040s).

2040s) does not suggest early onset or late withdrawal of the monsoon rains over the Indian subcontinent in either of the two anomaly experiments (Figure 13). The simulated decline in monsoon rainfall in experiment S is found to be statistically significant at 90% confidence level. Moreover, while an increased frequency in the intense spells of monsoon rainfall is observed in greenhouse gas forcing experiment, a decline in the frequency of heavy rainfall spells (> 10 mm day^{-1}) is simulated by the model in the combined greenhouse gas and aerosol forcing experiment.

The results presented above highlight the potential influence of combined greenhouse gas and aerosol forcings on the monsoon climate. A more rigorous statistical assessment of the projected changes in monsoon climate and its implications for agriculture and ecosystems will form a separate study.

Conclusions

While there is, as yet, incomplete knowledge of the physical, chemical and radiative properties of aerosols, the available estimates on the mean climatological distribution of sulphate aerosols and the associated 'direct' negative radiative forcings have enabled climate modelling groups in the world (only two till date) to examine its impact on the greenhouse gas-induced warming. The preliminary results have been encouraging in that the scientific community has been able to attribute the observed increases in global mean temperature to anthropogenic activities of mankind with a degree of confidence.

The results obtained in ECHAM3 + LSG model simulation on the past trends in surface air temperature and rainfall are encouraging in that they are able to replicate, in a broad sense, the observed changes in monsoon climate over the Indian subcontinent and this enables us to place a moderate degree of confidence in the simulated climate change scenario presented here. The magnitude of projected surface warming in the decade 2040s over the study region is close to 1.0°C. A decrease of about 0.5 mm day^{-1} in summer monsoon rainfall is simulated by the model in numerical experiment with combined greenhouse gas and aerosol forcings.

It would be interesting to confirm on these findings in other model simulations as and when the required data are made available. A better understanding on the aerosol forcings, increased supercomputing power to perform numerical experiments at finer resolution and improved knowledge of some of the physical processes, which are currently only approximated in parametrization schemes, in coupled atmosphere–ocean climate models are required to provide a more confident regional climate change scenario.

ACKNOWLEDGEMENTS. M.L. thanks Deutsches Klimarechenzentrum GmbH (DKRZ) and Max Planck Institute for Meteorology, Hamburg for generous hospitality and for extending facilities to take up this study. The visit of M.L. to DKRZ was funded by the German Ministry for Education, Research and Technology (BMBF). We are grateful to Prof. K. Hasselmann and Prof. L. Bengtsson for their keen interest in this study. Dr E. Roeckner made valuable suggestions during the course of this study. The Meteorological Institute of Stockholm University provided the aerosol forcing data used in the numerical experiments. The assistance of Ms. Marion Grunert in drafting the illustrations is appreciated.

Surinamite (Be, B, Ga) from cordierite gneisses of eastern ghat mobile belt, India

P. V. Ramesh Kumar, K. K. V. S. Raju and B. S. Ganga Rao*

Department of Geology, Andhra University, Visakhapatnam 530 003, India
*Birla Periclase, Visakhapatnam 530 003, India

Surinamite rich in beryllium, boron and gallium is a monoclinic mineral under group $P2_1/a$ with a = 9.648 Å, b = 11.337 Å, c = 4.981 Å, V = 515.13 Å^3 and Z = 4. Chemical analysis yields the idealized formula as $(Mg, Fe, Mn, Be, Ga)_{3.72}(Al, B)_{3.81}Si_{2.78}O_{15}$. The strongest diffractions in the powder pattern are: (d Å, I, hkl) – 3.7892 (46) (2̄11), 2.6763 (61) (3̄30), 2.436 (100) (041), 2.186 (40) (4̄21), 2.0411 (79) (232), 1.993 (90) (032), 1.8195 (65) (350). Surinamite occurs as an individual greenish blue crystal with characteristic purplish violet pleochroism and has a density of 3.24 g/cc (measured) and 3.27(x) (calculated). It is biaxial negative, $2V_\alpha$ = 68–70°; the refractive indices are α = 1.735, β = 1.739, γ = 1.744; birefringence is moderate to high; $b = Y$; Z = greenish blue, Y = purplish blue and X = brownish violet to yellow. Surinamite (Be, B, Ga) is associated with cordierite, sillimanite, sapphirine, spinel, monazite and quartz. Chemistry indicates couple substitutions as Be and Ga for Mg, Fe, Mn and Al, B for Al, and Al, B for 2 Si. Metamorphic origin has been attributed to this new mineral and such an existence is being reported for the first time from India.

DURING an investigation of sapphirine-associated minerals from cordierite gneisses at various places (locations given in Table 1), we noted some bright greenish blue platy elongated crystals associated with cordierite from eastern ghat mobile belt (EGMB) of Vijayanagaram District, India. About 30 grains of 40 μm size were

separated from cordierite gneiss using Frantz isodynamic separator and finally handpicked using a binocular microscope; the grains were assumed as 99.99% pure. Later subjected to Philips X-ray diffractometer (XRD), the powder pattern resembled that of surinamite as described by de Roever *et al.*[1], suggesting that the mineral was similar to surinamite sensustricto (JCPDS 29-702).

The mineral was found in cordierite gneisses from different localities along with cordierite, sillimanite, green spinel and sapphirine. Accessories comprised ilmenite–magnetite as opaque minerals, monazite and quartz. The sillimanite was present in two generations: (1) rather large platycrystals and (2) small fibrous crystals in aggregates together with the mineral surinamite. Surinamite, in small crystals up to 0.4 mm in size, was found in aggregate together with cordierite and sillimanite. Intergrowths were found between sillimanite and surinamite. About 30–40 grains of surinamite were observed in thin sections of the samples GR 222 and SN 275.

The crystal habit was found to be platy parallel to (010) with one set of well-developed cleavage perpendicular to (010). Optically, surinamite is biaxial negative with $2V_\alpha = 68–70^\circ$ for light 486 μm; refractive indices are: $\gamma = 1.744$, $\beta = 1.739$ and $\alpha = 1.735$. The birefringence is moderate to high. The optical plane is always parallel to (010). The mineral is monoclinic with an optic orientation of $b = Y$. The pleochroic colours of the mineral in almost all the samples are well pronounced as Z = greenish blue, Y = purplish blue expressing dominant purplish glow and X = brownish violet glow to yellow (Figure 1). This is the only mineral expressing glowing brownish violet colour during determination of pleochroism, in contrast to the less pronounced versions of bluish green colours in sapphirine. Hence, the mineral is distinct in its optical characteristics. This variety of the surinamite is reported for the first time from eastern ghat granulite belts of India. The specific gravity was determined to be 3.24 g/cc using the pycnometer technique. The calculated specific gravity from the X-ray data is 3.27(x).

X-ray powder patterns were taken on a Philips X-ray diffraction system PW 1730/PW 1390 with generator setting at 35 kV, 20 mA (Cu-kα radiation having a wavelength of 1.54184 Å; scan speed fixed at 0.04° 2θ/s; 2θ range from 10° to 100°) are presented in Table 2. The X-ray pattern (Figure 2) shows the surinamite to be monoclinic with a possible space group $P2_1/a$. The refined cell parameters[2] were determined to be a_0 = 9.648 Å, b_0 = 11.337 Å, c_0 = 4.981 Å, $\beta = 109° 11'$ and $V = 515.13$ Å^3 with $Z = 4$. The strongest lines are almost all similar to those of surinamite described by de Roever *et al.*[1], except that a few high-angle reflections are less sharp in the pattern for the sample. A few weak reflections are also present in the XRD patterns. Some of the reflections may also belong to the surinamite of the

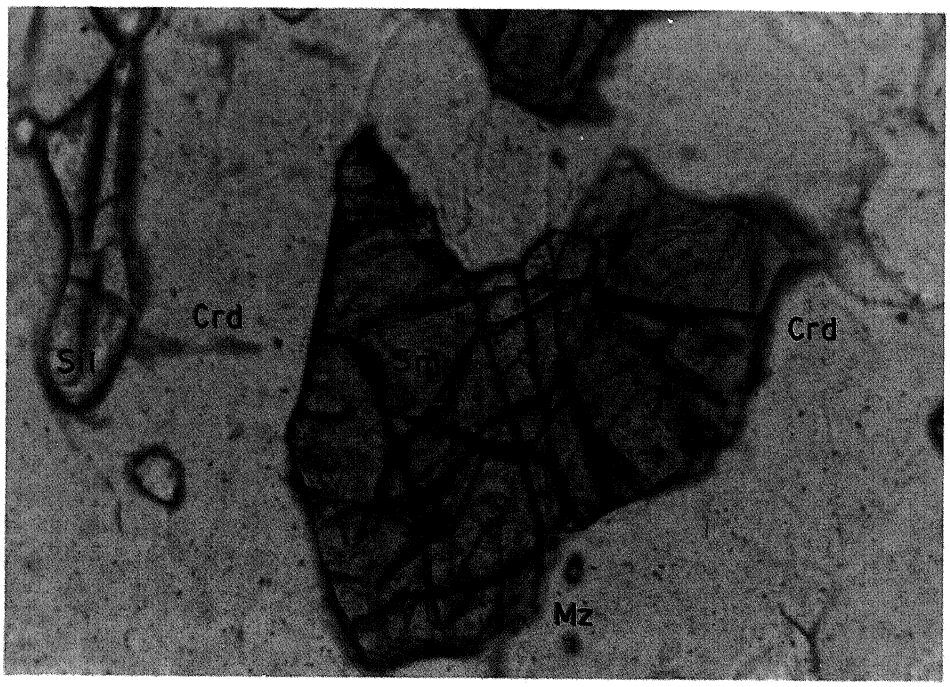

Figure 1. Photomicrograph showing surinamite (Sm) in brownish violet colour to its natural size of 40 μm enclosed within the cordierite (Crd) associated monazite (Mz) crystals with pleochroic haloes along with sillimanite (Sil) (under plane-polarized light 40×).

present study area and could have been obscured in the film of de Roever *et al.*[1] by fluoroscence of Fe excited by Cu radiation.

The crystal structure of surinamite[3] is represented as a polyhedral diagram projected down Z between $0 < Z < \frac{1}{2}$ in Figure 3, based on cubic close-packing of the oxide anions having layers stacked parallel to (001). With essentially Be, B and Ga the cell contents are $M_{24}T_{20}O_{64}$, where M = octahedrally coordinated and T = tetrahedrally coordinated cations by oxygen anions. The atomic occupancy positions for surinamite are given in Table 3. Assuming fully occupied sites, the surinamite cell can have composition $M_9T_5O_{16}$, where M_9 = 3.893 Al + 2.893 Mg + 0.932 Fe + 0.007 Mn + 1.261 Be + 0.04 Ga and T_5 = 3.707 Si + 0.746 Al + 0.547 B is obtained by the additivity rule. The site occupancies of Be and Ga at octahedral positions and B in tetrahedral positions clearly show that no vacancy exists and the structure is fully occupied maintaining the mineral stoichiometry.

Optically pure separated mineral grains of surinamite were chemically analysed using inductively coupled plasma-mass spectrometer (ICP-MS) (plasmaquad (VG Elemental, Winsford, UK) controlled by an IBM PC-XT computer and associated software) using acceleration potential of RF-1300 W. The carbon-coated samples were checked with the aid of a wavelength-dispersive spectrometer X-ray counting system (WDS XRCS) attached to a scanning electron microscope (SEM) (JEOL JSM-T 330 A) using acceleration potentials of 20 kV. Be, B and Ga were determined from the same sample powders using Perkin Elmer 2380 atomic absorption spectrophotometer (AAS) with acetylene and nitrous oxide as burning fuels. International standards (FeR_2–FeR_4 (G.S. Canada); GIT-IWG of France and G_2 of USGS) were used for analysis with ICP-MS, WDS/SEM and AAS. The results of the complete chemical analysis are presented in Table 1. The average chemical formula calculated on the bases of 15 oxygen atoms is

$$(Mg, Fe, Mn, Be, Ga)_{3.719}(Al, B)_{3.81}Si_{2.78}O_{15} \text{ with } Z = 4.$$

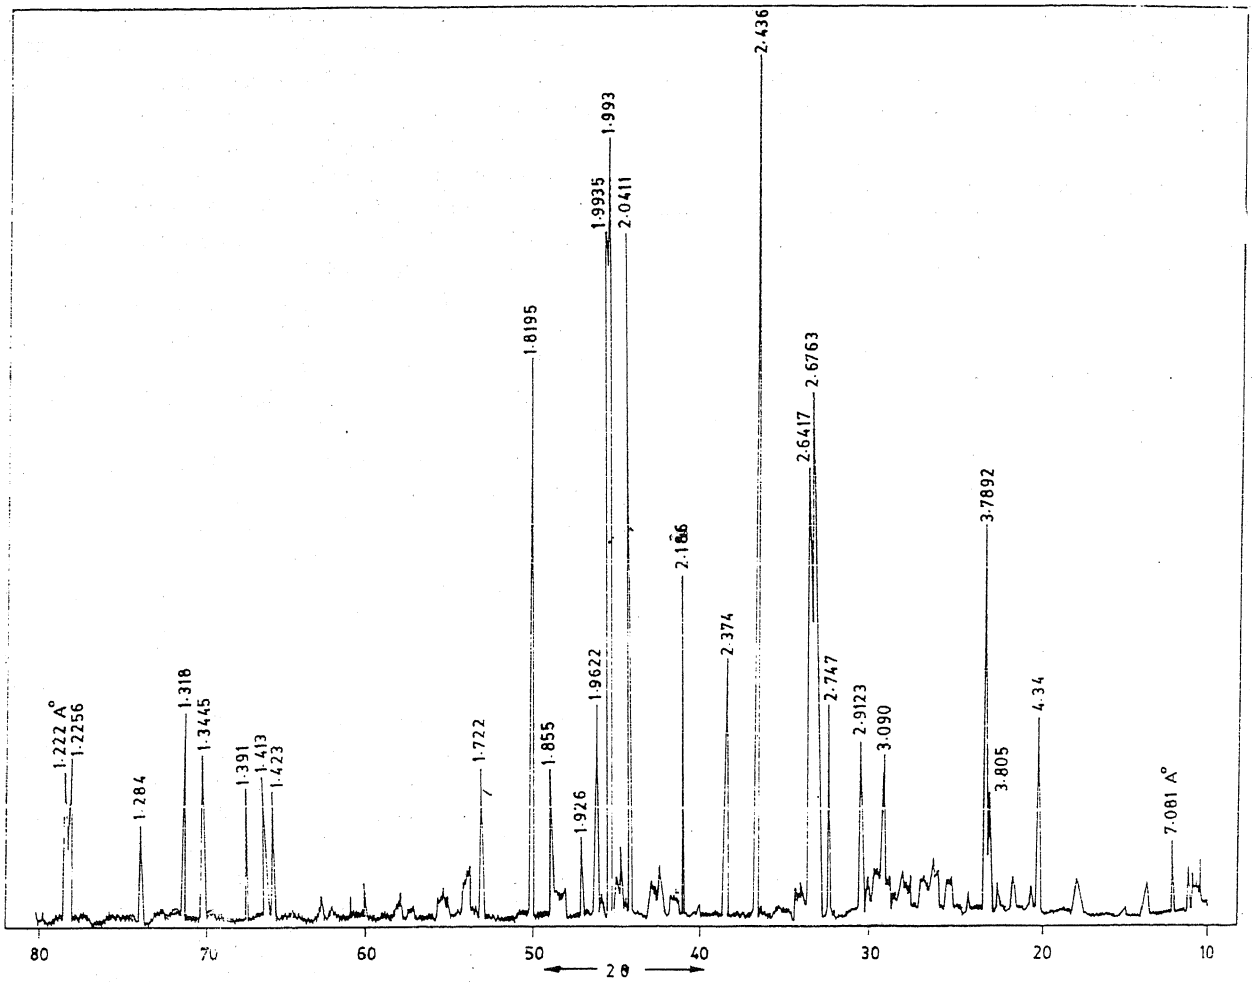

Figure 2. Abridged form of the X-ray diffractogram of surinamite.

The amount brings the analytical totals of the study area samples in the 97.93–99.86% range and the results show reasonable stoichiometry. Clearly, there is a series of cations extending between Mg–Fe–Mn–Be–Ga member and Al–B member of the surinamite. Because Mg, Fe and Mn ions are larger than Be and Ga, and similarly Al and B in the type material. Substitution of a trivalent or bivalent cation for a similar charged cation does not require much compensating mechanism. Exchange operations, if needing coupled substitutions, are technically feasible because the charge compensations can occur in the VIII, VI and IV coordinations for elements like Mg, Fe, Mn, Al which with higher dimensions can easily accommodate Be (0.27 Å) and Ga (0.62 Å) in their respective vacant sites. Charge compensations in the tetrahedral aluminium site could have occurred via the exchange operation with B (0.11 Å). An ionic substitution have both-ways direction (AlSi ↔ SiAl) up to a magnitude to balance the charges and it is logical to treat exchange operators as vectors. In terms of the magnitude, not only can the extent of AlSi four-coordination substitution vary, but it can also be applied to the operation once to change B in the place of substituted Al and Si. Hence, coupled substitutions[4] might have occurred conveniently and compactly as exchange operators, maintaining charge quantities of the elements replaced without disturbing the compact structure of surinamite, and were roughly coeval. Embayed cordierite-associated surinamite and fibrous sillimanite with quartz grain inclusions clearly suggest that breakdown reaction might have occurred at very high pressures during the isobaric cooling of the cordierite gneisses in the area. The reaction may be given as[1]

3 cordierite → 2 surinamite + 2 sillimanite + 7 quartz,

$$3(Mg\ Fe\ Mn)_2\ Al_3\ (Si_5Al)\ O_{18} \rightarrow 2(Mg\ Fe\ Mn)_3\ (Al\ Fe)_4\ Si_3\ O_{15} + 2\ Al_2\ SiO_5 + 7\ SiO_2\ .$$

Some of the chrysoberyl-bearing pegmatites (pegmatite: a plutonic rock of granitic affinity) are the

possible source of Be in surinamite at this locality, whereas B and Ga are derived from the original metasediments represented as sillimanite gneisses[5] associated with the khondalites and cordierite gneisses of the study area. Beryllium-, boron- and gallium-bearing surinamite mineralization associated with the cordierite gneisses in a granulite facies terrain may reveal previously unknown geochemical features of the khondalite suite of rocks in the EGMB.

The transition between garnet and spinel peridotites, caused by the reaction orthopyroxene + spinel = olivine + garnet, has been envisaged in the harzburgites of Indus Ophiolite Belt based on petrographic and geochemical studies. The reaction has been tested in the light of evidence available from phase equilibrium experiments on such transition.

THE harzburgites represent the lowermost section of ultramafic rocks, exposed as tectonically transported materials within the rocks of Dras Volcanic Group[1] or Sangeluma Group[2]. The harzburgite is made up of olivine + orthopyroxene + spinel, with modal abundance of 65 : 32 : 2% and trace amount of clinopyroxene. The harzburgites typically show a transitional texture between protogranular and porphyroclastic texture[3] or porphyroclastic texture[4]. Olivines occur both as porphyroclast (Fo 90.58–92.13) and neoblast (Fo 90.57–91.53). The former varies in grain size from 2 to 4 mm, while the latter varies from 0.5 to 1.5 mm. Majority of the porphyroclasts show development of strain shadows and kink bands. Orthopyroxene porphyroclasts are larger than olivine and vary in size from 3 to 6 mm. Both olivine and pyroxene porphyroclasts have irregular serrated grain boundaries. The pyroxene porphyroclasts are armoured by fine granular aggregates of crushed olivine and pyroxene. The porphyroclasts of orthopyroxene typically show stretching or elongation and are kinked, and often show exsolution lamellae of clinopyroxene. Besides the occurrence of clinopyroxene as exsolution lamellae, it rarely occurs as minute grains within the cluster texture; otherwise they are absent in the rock. Because of their fine grain size their individual microbe analysis is not possible. The contrast in their grain size with the rest of the assemblage and the absence of any deformational features in them raises some doubt as to whether the clinopyroxene is primary. Olivine neoblasts occurring in clusters show a close common orientation, indicating polygonization and recrystallization of former larger grains. One of the significant observations in the harzburgites is that the spinel occurs as fine-grained intergrowths with orthopyroxenes (Figure 1), in a fashion similar to the so-called finger print

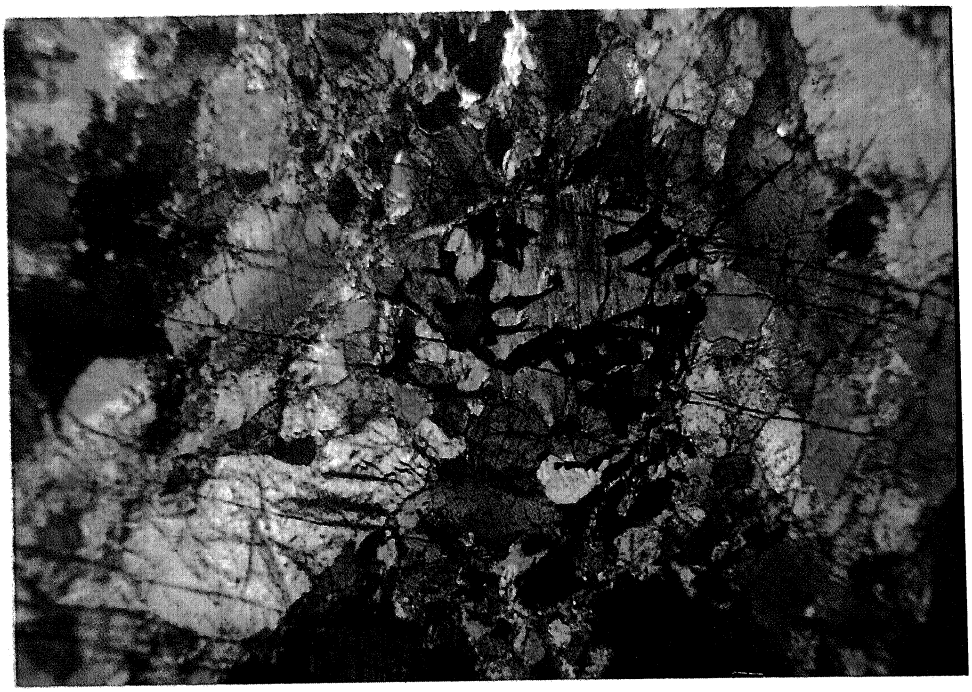

Figure 1. Photomicrograph of harzburgite showing symplectic intergrowth of aluminous spinel with orthopyroxene.

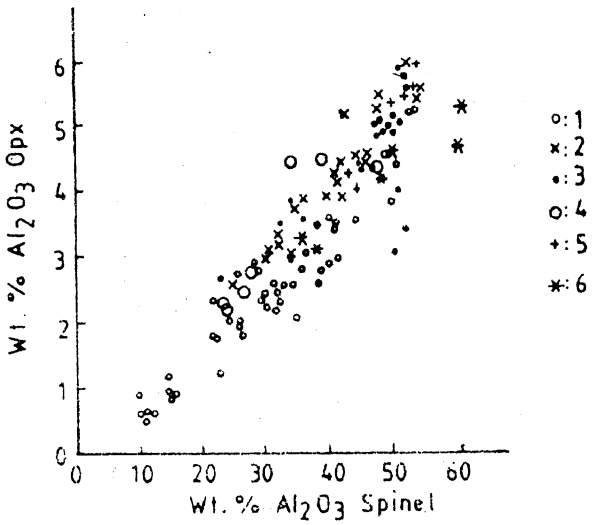

Figure 2. Plot of alumina content of coexisting enstatite and spinel in ophiolitic peridotites. **1**, 'ophiolitic' alpine peridotite; **2**, central Indian ridge; **3**, SW Indian ridge; **4**, mid-Atlantic ridge; **5**, America–Antarctic ridge; **6**, present investigation.

spinels[5]. The proportions of pyroxene and spinel in the cluster cannot be determined accurately because of the irregular boundaries of the aggregates. Though olivine is a dominant phase in the rock it is mostly lacking in the spinel pyroxene graphic intergrowth. The spinel is reddish-brown in colour and besides forming a part of the symplectite intergrowth also occurs as subhedral to euhedral grains interstitial to olivine and orthopyroxene. Concentration of spinel into 'holly leaf' texture was also observed in one of the samples. Composition of orthopyroxenes in clusters is similar to composition of independent orthopyroxene grains in the rock, and any textural explanation should account for the uniformity.

Orthopyroxenes are typically rich in MgO (En 89.21 to 90.32 Fs 7.67 to 9.29 Fm 0.078 to 0.092) content. The Al_2O_3 content of the pyroxene grain ranges from 2.93 to 4.46 wt%. The Mg/Mg + Fe ratio shows a general inverse relationship with the Al_2O_3 content. The spinels are typically rich in Al_2O_3 content, which varies between 32.1 and 53.58 wt% (Table 1). An increase in Cr_2O_3 with decrease in Al_2O_3 was observed form sample no. 32 to 113A, 113B. In the 100 Cr/(Cr + Al) vs 100 Mg/(Mg + Fe) diagram[6] they occupy the field of spinels from ultramafic xenoliths. The Cr and Mg contents behave inversely. The spinel analysis shows them all to be highly aluminous and magnesian, but appreciable amount of chromium and total iron are also present. They are probably best regarded as ferroan chrome spinel.

The strong correlation between Al_2O_3 content of orthopyroxene and spinel found in Figure 2, cannot be just a coincidence but suggests Al partitioning between pyroxene and spinel and supports their co-genetic nature.

The spinel–orthopyroxene symplectite intergrowth texture is seen to be a notable feature of lherzolite/harzburgite nodules as well as alpine peridotites. This texture has been attributed to a variety of origins, viz:

(i) Primary crystallization from pools of melt concentrated during partial fusion[5]: However, pyrometamorphic textures are absent in the studied samples. Besides, the preservation of such original texture seems unlikely considering the deformation that the rock has undergone.

(ii) Mechanical concentration of spinel and pyroxene during deformation[3]: This can explain the concentration of spinel into 'holly leaf' textures. But it cannot explain its strict association only with pyroxene and not with olivine. Alumina partitioned between spinel and enstatite as indicated by the strong correlation cannot be a mere coincidence.

(iii) Exsolution of spinel and diopside from a former aluminous pyroxene[3]: This requires non-stoichiometric conditions for both spinel and pyroxene. Besides, higher values of Al_2O_3 of almost 24 wt% are envisaged for the original pyroxenes. The temperature pressure values required to equilibrate such pyroxenes are unrealistic. The observed high chrome content of the spinel in the sample is in contrast to such an origin.

The absence of plagioclase in the rock under study as well as the low calcic nature of the small clinopyroxene and the high Cr_2O_3 content of the spinel in the cluster texture preclude the possibility of the cluster texture being a product of the reaction between forsterite and anorthite. Similarly, the reaction forsterite + Al-clinopyroxene = spinel + diopside fails to explain the low modal abundance of clinopyroxene in the rock (< 1 vol.%), the strict association of spinel only with orthopyroxene (enstatite) and not with diopside, as well as the observed strong correlation between Al_2O_3 of the orthopyroxene and that of the spinel.

The only feasible explanation is their formation by the reaction

$$\text{pyrope} + \text{olivine} = \text{orthopyroxene} + \text{spinel} + \text{clinopyroxene}^7.$$

This appears to be attendant upon a fall in pressure from garnet peridotite facies to spinel peridotite facies conditions and is consistent with the experimental results[8,9]. The presence of clinopyroxene is additional to the phases in the reaction

pyrope + forsterite = enstatite + spinel

originally proposed[10], due to the addition of CaO to the system[11].

For garnet to react and yield pyroxene with the observed value of $t = 0.06$ the product should have 0.306 molar fraction of spinel[7], which is in good agreement with the measured results (0.30) in the present case. Higher values of t in some samples correspond to a lower modal abundance of spinel in the samples, and larger percentage of independent orthopyroxenes in the rock account for a low modal abundance of spinel. Besides, there is an absence of olivine and garnet in the cluster, indicating the complete reaction of garnet and olivine and conversion of original garnet peridotite assemblage to spinel peridotite. The postulated original garnet may be slightly rich in chrome content, similar in composition to the 'chrome pyrope' (> 4 wt% Cr_2O_3 and higher CaO) variety found in the garnet peridotite xenoliths of Montana diatreams[12]. This will also account for the Cr-rich nature of the spinel and also the small amount of the low calcic clinopyroxene present in the symplectite cluster. The orthopyroxene analyses includes the exsolution lamellaes of clinopyroxene; even then the CaO content in these orthopyroxenes rarely exceeds 1 wt%, which in itself is a proof to consider the low calcic nature of the minute clinopyroxenes in the symplectite. More direct evidences for the olivine–garnet reaction are many[13–15].

The transition from garnet to spinel peridotite as exhibited by the texture may occur during heating or decrease in pressure[13]. Occurrence of pyroxene exsolution lamellae in the rock indicates extensive cooling and so a pressure-induced reaction is more likely[7]. Certainly, such an diapiric movement of the mantle would be in keeping with the evidence of deformation-induced recrystallization textures observed in the sample. It has been shown that the reaction enstatite + spinel = forsterite + pyrope takes place in the pressure range 15–35 kbar at temperatures from 800 to 1600°C (ref. 10). A series of experiments on 'pyrolite' compositions define the stability fields of spinel peridotite and garnet peridotite and the reaction occurs at around 20 kbar in the temperature range 900–1300°C (ref. 16). The boundary is sensitive to the amount of R_2O_3 (Al_2O_3, Cr_2O_3) (ref. 17). Single pyroxene geothermometry[18] gives a temperature range of 1050–1100°C. The pressure values obtained from the Al_2O_3 isopleths and other parameters[19] range between 15 and 25 kbar, which agree well with the experimental values[20,21]. Thus, the garnet–olivine reaction model fits the rock better than any other alternative hypothesis. The reaction described here is reasonably interpreted as an adjustment of the primary high-pressure assemblage to a lower-pressure environment. A decrease in the confining pressure from 50 to below 20 kbar would move the garnet out of its stability field[14].

Garnet peridotite would be subject to pressure decrease during tectonic uplift or mantle upwelling; this may have been responsible for the formation of such symplectite texture. The cluster texture may, therefore, be an indicator of mantle convection. Occurrence of spinel–pyroxene symplectite intergrowth in the alpine peridotite or ultramafic xenolith can be taken as an evidence of garnet to spinel peridotite transition in the mantle.

Bilateral outgrowths on thorax of sepia eye colour mutants in *Drosophila bipectinata*

B. N. Singh, Seema Sisodia and Rakhee Banerjee

Department of Zoology, Banaras Hindu University, Varanasi 221 005, India

Flies with bilateral outgrowths on thorax were detected in sepia eye mutant stock of *Drosophila bipectinata*. A separate stock of sepia mutants with outgrowths on thorax could be established. Expression of this phenotypic change is better in females than in males and there is individual variation in both sexes. In order to understand the mode of inheritance of these outgrowths on the thorax of sepia mutants, four different crosses involving mutants and wild type flies were made. The proportion of flies with outgrowths on thorax varies in F_1 and F_2 generations of different crosses. Such outgrowths on the thorax have not been reported earlier in any species of *Drosophila* and appear to be a unique phenotypic change in *D. bipectinata* caused due to mutation but its exact nature could not be understood from the results of these crosses.

D. BIPECTINATA is a member of the *bipectinata* species complex of the *ananassae* subgroup of the *melanogaster* species group. This species is of common occurrence in India. Studies on population and behaviour genetics of this species have been initiated by Indian workers[1-9]. We detected sepia eye colour mutation (autosomal reces-

sive) in a wild stock of *D. bipectinata*[10] which diminishes sexual activity of males[8]. In sepia mutant stock, 17 females and 10 males showing two outgrowths on dorsal side of thorax were found. Figure 1 shows the photograph of a sepia mutant with two outgrowths on the dorsal side of the thorax. A separate line of sepia mutants showing outgrowths on thorax could be established. It has been observed that there is individual variation in both sexes in expression of this character and generally outgrowths are larger in females than in males. In the stock of mutants showing outgrowths, a few flies are regularly found which do not possess outgrowths on their thorax. In the sepia mutant stock also, a few flies with outgrowths are regularly found.

To understand the mode of inheritance of this unique phenotypic change, four different crosses were made. All the crosses were made in food bottles by using wild type, sepia mutants with and without outgrowths on thorax (normal thorax). In each cross, a large number of F_1 flies were observed to score the number of flies with/without outgrowths on thorax. A random sample of 50 flies (females and males in equal number) from F_1 were transferred to a fresh food bottle to obtain the F_2 generation of each cross. F_2 flies were observed to score the different types of flies. Results of all four crosses are presented in Table 1. In reciprocal crosses (1 and 2) between sepia mutants with normal thorax and with outgrowths, both types of flies were found in F_1 and F_2 generations and the results of reciprocal crosses are more or less similar. The frequency of sepia mutants with outgrowths on thorax varies from 40 to 60% in F_1 and F_2 of these crosses. However, the results of reciprocal crosses between sepia mutants with outgrowths and wild type (red eye and normal thorax) flies are different from those of the crosses involving sepia mutants with normal thorax and with outgrowths on thorax. When wild type females were crossed with sepia mutant males with outgrowths, flies with outgrowths on thorax were absent in F_1. In the F_2 generation of this cross, red-eyed flies with outgrowths and without outgrowths as well as sepia mutants with outgrowths and without outgrowths were found but the frequency of flies with outgrowths was lower (23.58%) as compared to the crosses involving sepia mutants. In the opposite cross (sepia females with outgrowths × wild type males), seven females with very small outgrowths on thorax were found in the F_1 generation. In the F_2 generation, four types of flies were found and the frequency of flies with outgrowths on thorax was very low (16.75%). Thus the results of different crosses vary and development of outgrowths on thorax occurs in both wild type (red eye) and sepia mutants of *D. bipectinata*.

A new empirical relation for strong seismic ground motion for the Himalayan region

Ashutosh Aman, Umesh K. Singh and Ramesh P. Singh

Department of Civil Engineering, Indian Institute of Technology, Kanpur 208 016, India

Strong ground motion data from five earthquakes that occurred along the Himalayan range have been taken to study the attenuation characteristics of horizontal peak acceleration and velocity. Using these data, we have found empirical relations for horizontal acceleration and velocity. These empirical relations for peak horizontal ground acceleration and velocity give good fit with the observed strong ground motion in the Uttarkashi earthquake of 20 October 1991. The attenuation relations found in the present study will be useful in estimating the peak horizontal ground acceleration and velocity of future earthquakes and will also be useful in designing earthquake-resistant structures in the Himalayan region.

EARTHQUAKE-resistant design of structures require estimate of the expected ground motions at the earthquake-prone sites. In order to develop ability to reasonably assess the expected ground motion due to future earthquake, it is essential to study the characteristics of strong ground motion recorded in the past earthquakes. Prediction of peak ground acceleration and velocity is useful to obtain an estimate of the outer envelope of the ground motion spectrum[1]. Peak ground motions are important in earthquake safety analysis and in the evalua-

Table 1. Earthquakes considered in the present work

Earthquake	Date of occurrence	Magnitude (M_B)
Dharamsala	26 April 1986	5.7
Meghalaya	10 September 1986	5.7
Burma–India	14 May 1987	5.7
Tripura–Assam	6 February 1988	5.8
Gauhati	6 August 1988	7.2

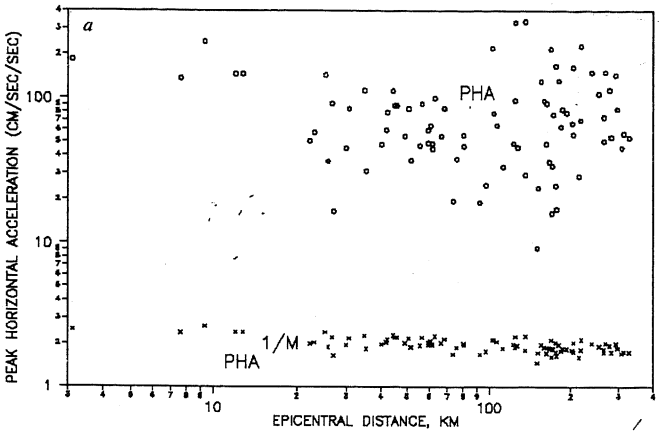

Figure 1 *a*. Observed peak horizontal acceleration (PHA) and its raised power ($PHA^{1/M}$).

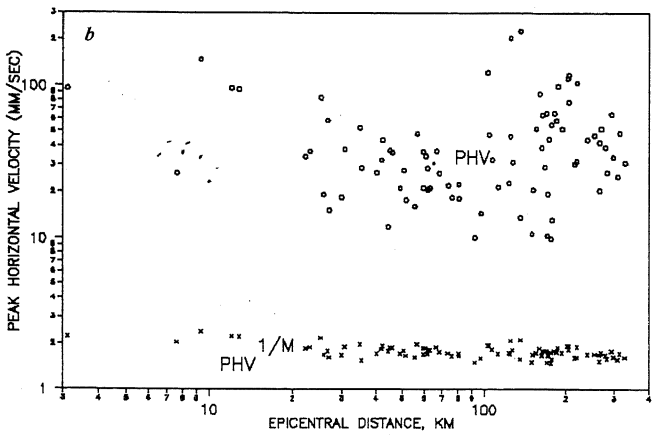

Figure 1 *b*. Observed peak horizontal velocity (PHV) and its raised power ($PHV^{1/M}$).

tion of earthquake design parameters. In order to predict peak ground motion data, the knowledge of attenuation relations of strong seismic ground motion of different regions is important. Such relations have been developed for USA[2–9], Canada[10], Japan[11] and Europe[12,13]. Such data are useful to seismologists and earthquake engineers to characterize strong ground motion and to prepare new regional seismic zoning map of different regions. In the past, most of the workers have widely used the following empirical relations given by Kanai[14]

$$\log_{10}(\mathrm{AGM}) = b_1 + b_2\ M - b_3\ \log_{10} R,$$

where AGM refers to the amplitude of ground motion parameter (acceleration or velocity) under consideration, M is earthquake magnitude, R is epicentral distance, and b_1, b_2 and b_3 are coefficients which are dependent on numerous parameters, including geology of the region.

The strong ground motion data for Indian region were almost nonexistent before 1986 and therefore no estimate for either ground motion parameters or these three coefficients was made for Indian region. After 1986, however, a number of strong motion records are available from earthquakes in the Himalayan region. In the present work, strong ground motion data[15] from five earthquakes recorded along the Himalayan region during the period 1986–91 have been examined. The details of these earthquakes are given in Table 1. The strong ground motion data have been used to determine empirical relation to predict peak horizontal acceleration and velocity for future earthquakes along the Himalayan region. Figure 1 *a* and *b* shows peak horizontal acceleration and velocity respectively, from five earthquakes that occurred along the Himalayan region (Table 1). The observed peak horizontal acceleration and velocity have been raised to power $1/M$, where M is the magnitude of the earthquake (Figure 1). Figure 1 *a* and *b* shows variations of $a^{1/M}$ and $v^{1/M}$ with epicentral distance, R, which shows almost a linear trend. From these data, we have found the following empirical relations which fit well with the observed peak horizontal acceleration (a) and velocity (v):

$$\log(a^{1/M}) = 0.433 - 0.073 \log(\mathrm{R}) \pm 0.037P, \quad (1)$$

$$\log(v^{1/M}) = 0.351 - 0.053 \log(\mathrm{R}) \pm 0.036P, \quad (2)$$

where $P = 0$ for 50th percentile and $P = 1$ for 84th percentile, and $\pm$ sign shows the upper and lower limits of the peak horizontal acceleration and velocity.

Variation of peak horizontal acceleration and velocity in Figures 2 *a–e* and 3 *a–e* is shown respectively, with epicentral distance R for all the five earthquakes that occurred along the Himalayan region. It is clear from these figures that the peak horizontal acceleration and velocity decrease with epicentral distances at different rates for different earthquakes. The amplitude of the observed peak horizontal acceleration and velocity shows variation with the epicentral distance. These variations are due to the difference in the magnitude of the individual earthquakes. The qualitative nature of the variation with the epicentral distance in all these earthquakes is almost similar. The data are very much scattered. The error bars show the 84th percentile values of the peak horizontal acceleration and velocity given for individual earthquakes (Figures 2 *a–e* and 3 *a–e*).

Using equations (1) and (2), we have computed peak horizontal acceleration and velocity for each individual

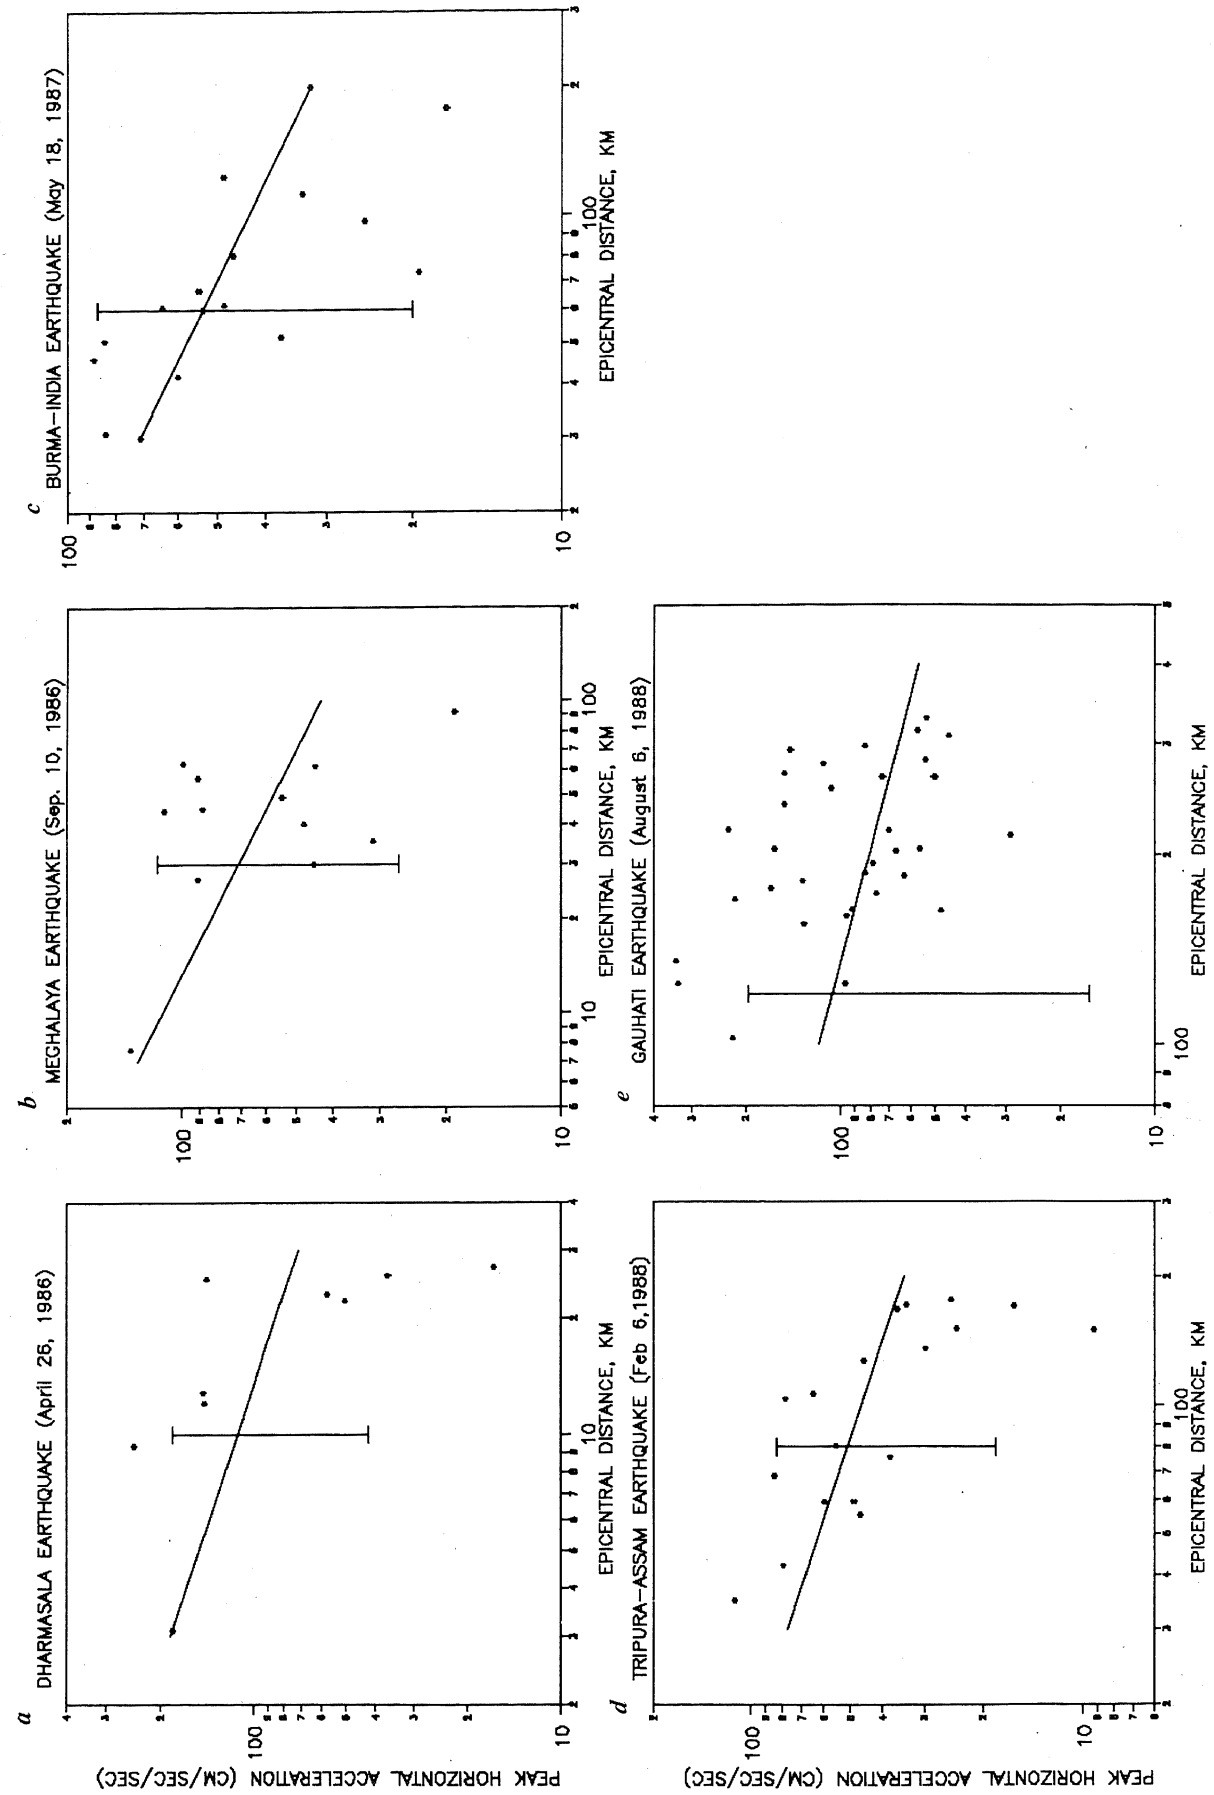

Figure 2 *a–e.* Observed peak horizontal acceleration, the solid line shows calculated acceleration from the empirical relation developed in the present work.

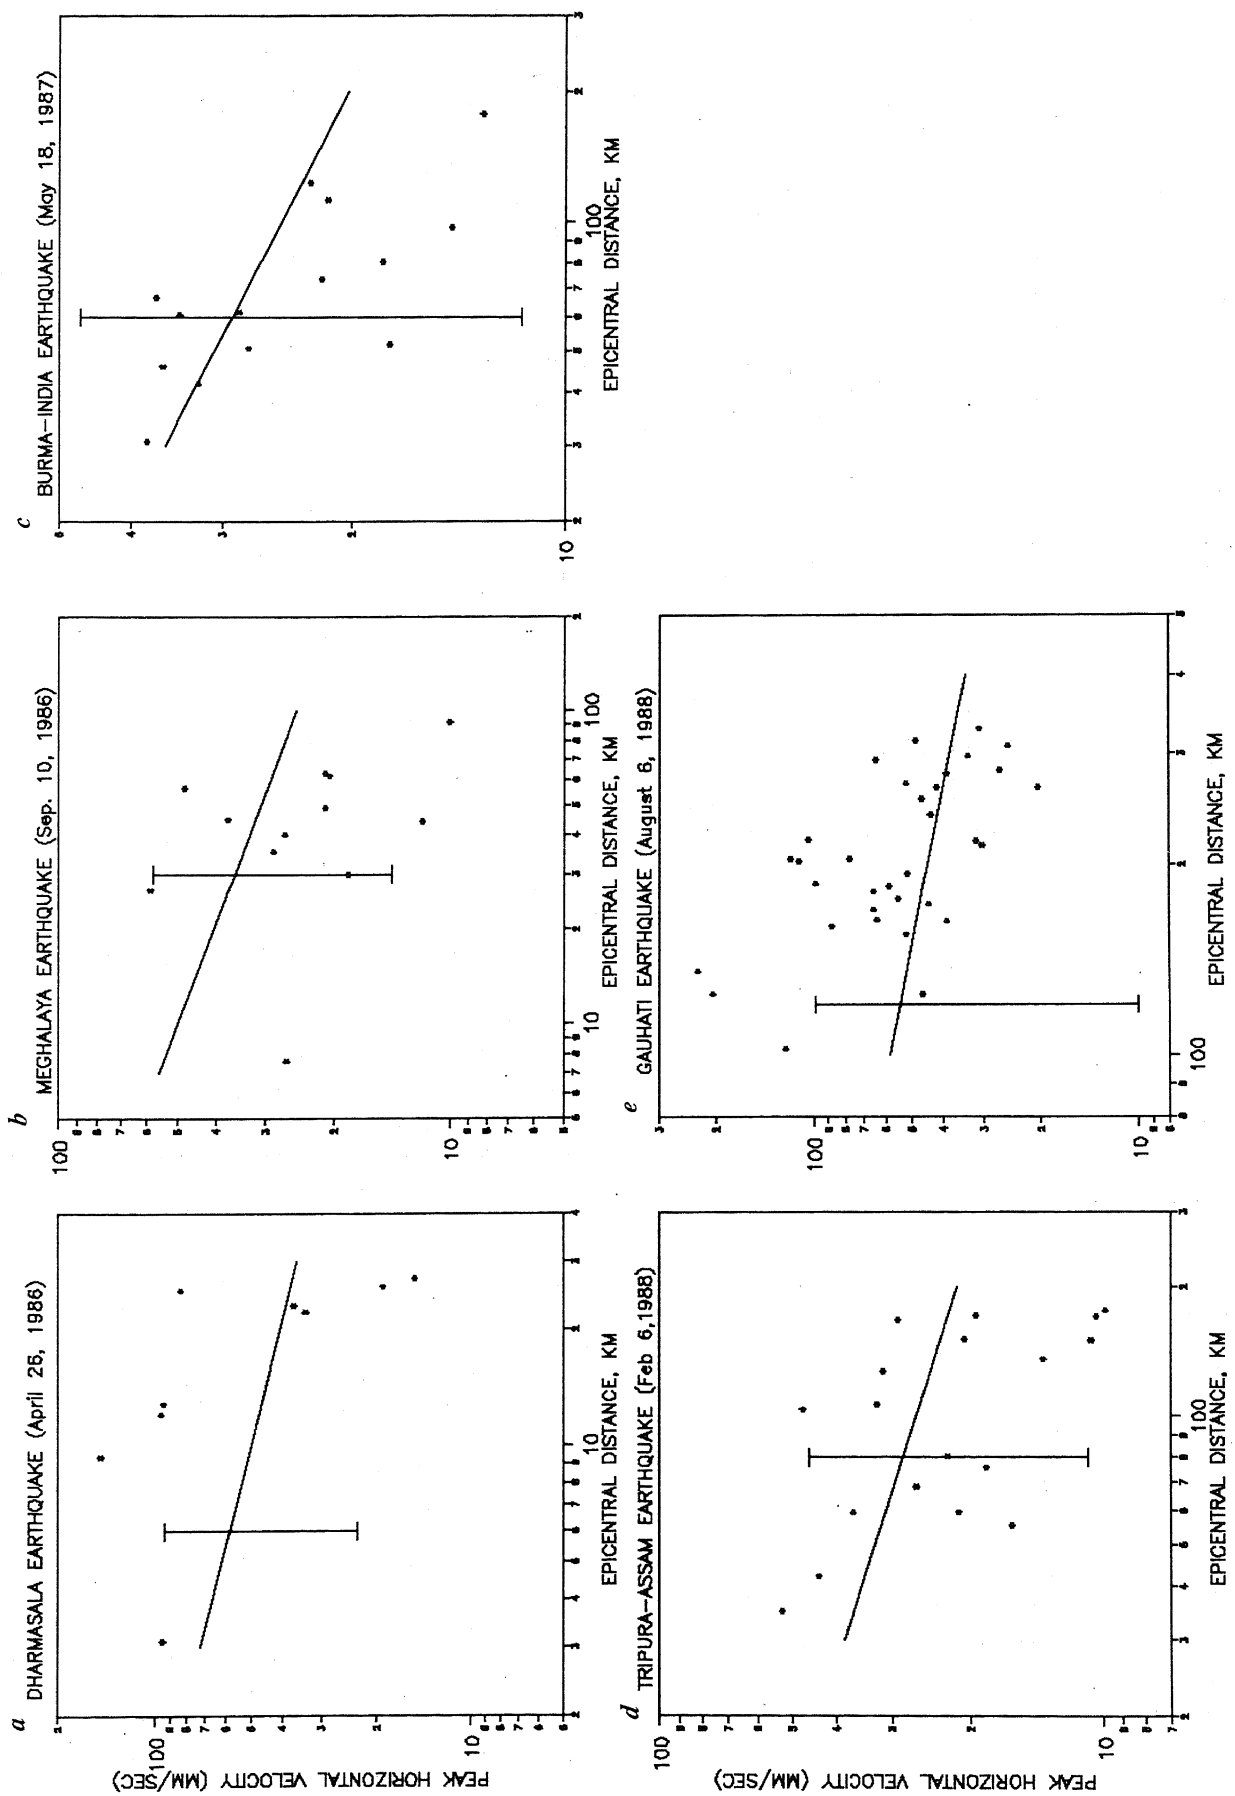

Figure 3 *a–e*. Observed peak horizontal velocity, the solid line shows calculated acceleration from the empirical relation developed in the present work.

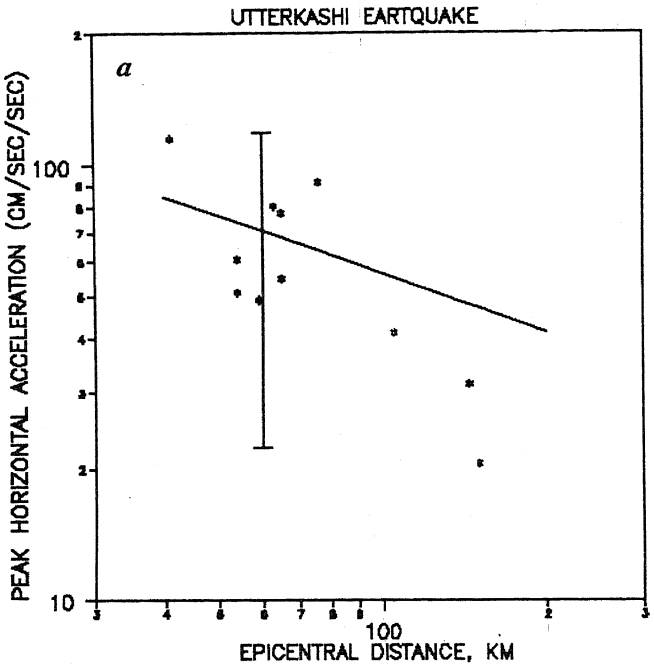

Figure 4 *a*. Observed peak acceleration in the Uttarkashi earthquake of 20 October 1991, the solid line shows theoretical predicted peak horizontal acceleration.

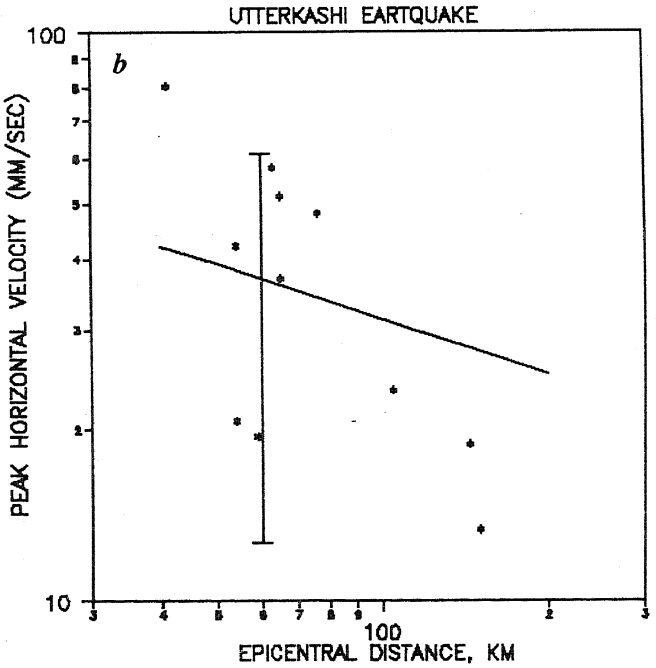

Figure 4 *b*. Observed peak velocity in the Uttarkashi earthquake of 20 October 1991, the solid line shows theoretical predicted peak horizontal velocity.

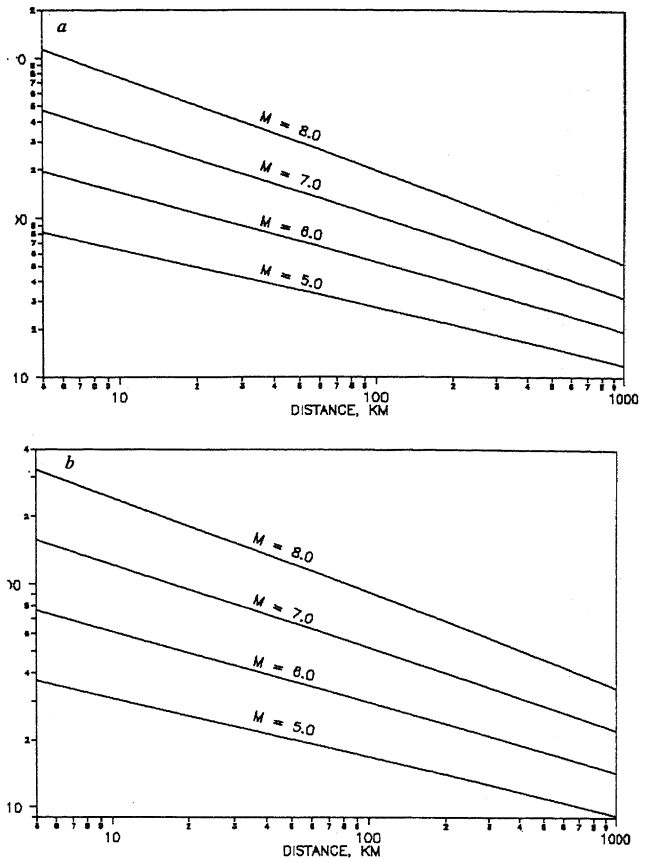

Figure 5 *a* **and** *b*. Predicted peak horizontal acceleration (*a*) and velocity (*b*) for earthquakes having various magnitudes.

earthquake which is depicted by the solid line in Figures 2 *a–e* and 3 *a–e*. It is evident that our empirical relations can explain the observed data quite nicely.

The validation of the above empirical relations has been carried out with the observed strong ground motion data[16] in the Uttarkashi earthquake of 20 October 1991 (magnitude 6.1). The observed peak horizontal acceleration and velocity of the Uttarkashi earthquake with epicentral distances are shown respectively in Figure 4 *a* and *b*. The solid curve is the predicted acceleration and velocity which is found to be in agreement with the observed strong ground motion.

Following the attenuation relations developed in the present work, we have evaluated the expected peak horizontal acceleration and velocity for earthquakes of varying magnitudes ($M = 5$, 6, 7 and 8) in the Himalayan region (Figure 5 *a* and *b*). It has been found that the maximum peak horizontal acceleration of about 1.12 *g* (Figure 5 *a*) may be observed in the vicinity of 5 km from the epicentre, which can produce peak horizontal velocity of about 320 mm/s (Figure 5 *b*) in any future earthquake in the Himalayan region.

In conclusion, we have found new empirical relation for peak horizontal acceleration and velocity. These

attenuation relations will be extremely useful in estimating strong ground motion parameters for future earthquakes in the Himalayan region. The present relations show the estimate of peak horizontal acceleration and velocity up to 1000 km from the epicentre of the earthquakes. Such relations are also needed for other major geological regions of India, e.g. Indo-gangetic basin and Peninsular regions, which can only be developed after having huge data base of the strong ground motion data from future earthquakes in these regions. Such relations will provide a useful guideline to the professional engineers while planning for major structures in the Himalayan region.

Involvement of calcium in brassinolide and auxin-induced cell elongation

Anitha Naren, T. G. Prasad, V. R. Sashidhar and M. Udaya Kumar

Department of Crop Physiology, University of Agricultural Sciences, GKVK, Bangalore 560 065, India

Coleoptile segments incubated in brassinolide (BR) or auxin (IAA) along with calmodulin inhibitor, chlorpromazine (CPZ) or calcium chelating agent (EGTA) or calcium surface antagonist, lanthanum chloride ($La^{+3}Cl_3$) resulted in inhibition of BR and IAA-induced elongation growth of coleoptiles. Pretreatment of coleoptile segments for 4 h with EGTA or $La^{+3}Cl_3$ also inhibited both BR and IAA-induced growth. Coleoptile segments with enriched endogenous levels of free calcium showed more elongation in the presence of BR or IAA. However, BR and IAA were ineffective in inducing coleoptile growth in the presence of calcium inhibitors. Results indicated that BR and IAA act through calcium and or calmodulin protein in inducing elongation growth in coleoptile.

BRASSINOSTEROID, a novel plant growth-promoting steroidal lactone, was first isolated and identified from pollen grains of brassica (*Brassica napus*)[1]. Recently, the presence of this new class of plant hormones has been shown in a number of plant species. It has also been shown to be involved in growth responses in many test systems[2–5], especially inducing cell elongation and cell division[1,5–7]. In addition to acting independently, it is found to act synergistically with other growth hormones found in plants[3,8,9]. One such interaction widely reported is that between BR and auxin in inducing cell elongation[3,8,10]. Auxin-induced cell elongation has been shown earlier to be mediated through the release of Ca^{2+} from membrane vesicles, which on complexing with the calcium-modulated protein, calmodulin, results in the response. It is known that calmodulin modulates auxin-induced growth[11]. Though the involvement of calcium in auxin action has been recognized for many years[12], the nature of interaction between auxin and calcium is poorly understood. Auxin-induced elongation in pea epicotyl is blocked by treating the segments with calcium chelators (EGTA and CTC), calcium surface antagonist (Lanthanum) and calcium channel blocker, Verapamil. The existing evidence suggests that auxin causes calcium efflux. In recent years, Ca^{2+} has been regarded as a second messenger and in conjunction with the calcium-binding protein, calmodulin, has been reported to be involved in the regulation of a number of cell processes, both in animals and plants[13–17]. Because of the close mimicking of the action of auxin by BR, we hypothesize that the mechanism underlying BR-induced cell elongation could also be mediated through calcium. We test this hypothesis here by using surface calcium antagonist, calcium chelating agent and finally potent antagonists of calcium calmodulin protein.

Brasinolide (BR) chemical was obtained from Godrej Soaps Ltd, Bombay. Calmodulin antagonist – chlorpromazine (CPZ), calcium chelating agent – ethylene glycol-*bis*(aminoethyl)tetraacetic acid (EGTA) and calcium surface antagonist – lanthanum chloride ($La^{+3}Cl_3$) and indole-3-acetic acid (IAA) were from Sigma Co, USA.

The assay of cell elongation induced by BR and IAA was carried out using wheat coleoptiles. Wheat seeds

were sown in plastic trays filled with vermiculite and kept in the dark for 5 days at 24°C. The dark grown coleoptiles were then harvested under dim red light and 10 mm segments were excised by excluding 3 mm tip using a coleoptile cutter. Excised coleoptile segments were transferred to a beaker containing distilled water and kept floating for an hour prior to the experimental treatments.

A set of 10 presoaked coleoptiles was transferred to petri dishes (5 cm diameter) containing 10 ml of incubating medium consisting of 1 mM phosphate buffer (pH 6), various calcium chelator/calcium surface antagonist solutions (CPZ, EGTA and $La^{+3}Cl_3$) along with 10 µM IAA or 0.2 µM BR; suitable controls without IAA or BR were maintained in all experiments. The coleoptiles were incubated in dark for 20 h at 24°C and the increase in the coleoptile length was measured using a millimeter scale and magnifying lens.

In another set of experiments, coleoptile segments were preincubated in the above-mentioned calcium chelators/calcium surface antagonists solution for 4 h, the coleoptile sections were rinsed in distilled water, surface-dried and then transferred to IAA or BR solutions. The response in terms of coleoptile segment elongation was monitored.

An attempt was also made to examine the effect of IAA or BR on cell elongation of coleoptiles enriched with calcium. Calcium-enriched coleoptiles were obtained by planting wheat seeds previously soaked in 1% $CaCl_2$ solution and sown in vermiculite irrigated with 1% $CaCl_2$ solution. Following germination for 5 days, the coleoptiles were processed as mentioned above and incubated in either water, IAA or BR and the increase in length was monitored.

The presence of calcium calmodulin antagonist-CPZ along with IAA or BR inhibited elongation growth of the coleoptile segments. A concentration-dependent reduction in IAA or BR-induced growth was observed with increasing concentration of CPZ in the medium. At a concentration of 75 µM of CPZ about 50% inhibition of IAA and BR-induced elongation was observed and at a concentration of 140 µM, both IAA as well as BR-induced growth were completely inhibited (Figure 1).

The addition of increasing concentrations of calcium chelating agent (EGTA) or calcium surface antagonist, $La^{+3}Cl_3$ to the incubation media progressively decreased IAA as well as BR-induced elongation. IAA and BR-induced elongation was inhibited to an extent of 50% in the presence of 2–3 mM EGTA (Figure 2) and 1–5 nM of $La^{+3}Cl_3$ (Figure 3).

Coleoptile segments pretreated with CPZ showed reduced growth when transferred to IAA and BR. There was a concentration-dependent reduction in coleoptile growth with increasing concentration of CPZ used for pretreatment. Segments incubated in IAA (10 µM)

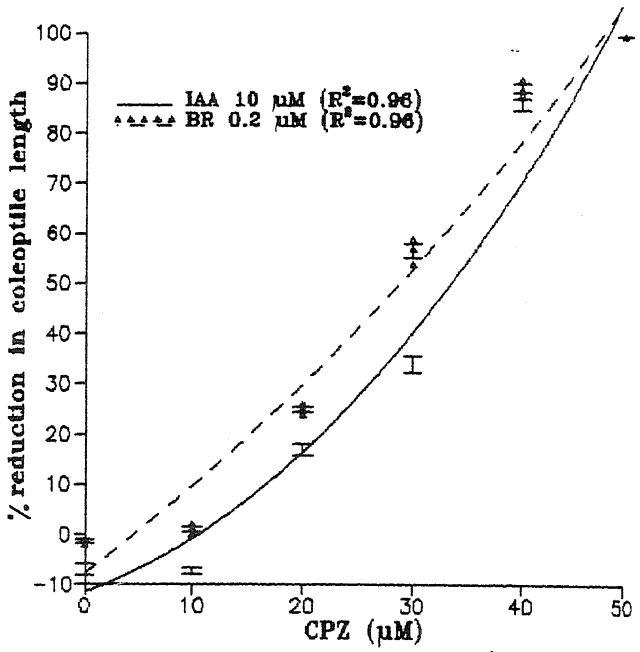

Figure 1. Effect of CPZ on IAA and BR-induced growth of wheat coleoptile segments. (Coleoptile segments were incubated in medium containing IAA (10 µM) or BR (0.2 µM) with different concentrations of CPZ. The final lengths of coleoptile segments were measured at the end of 24 h incubation in dark).

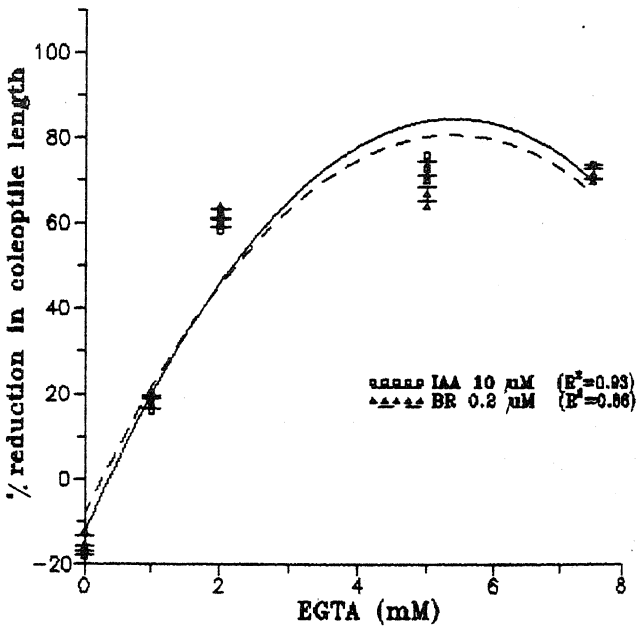

Figure 2. Effect of EGTA on IAA and BR-induced growth of wheat coleoptile segments. (Coleoptile segments were incubated in medium containing IAA (10 µM) or BR (0.2 µM) with different concentrations of EGTA. The final lengths of coleoptile segments were measured at the end of 24 h of incubation in dark).

Table 1. Effect of CPZ and EGTA on the extent of inhibition of growth of normal and calcium-enriched wheat coleoptile segments

Inhibitors	Calcium level in the coleoptile	Basal medium	IAA (10 μM)	BR (0.2 μM)
CPZ (50 μM)	Normal	30.60	81.30	63.93
	Enriched	84.33	92.16	81.00
EGTA (5 mM)	Normal	20.25	82.07	54.42
	Enriched	36.84	92.43	79.59

(% inhibition of growth over the respective control).

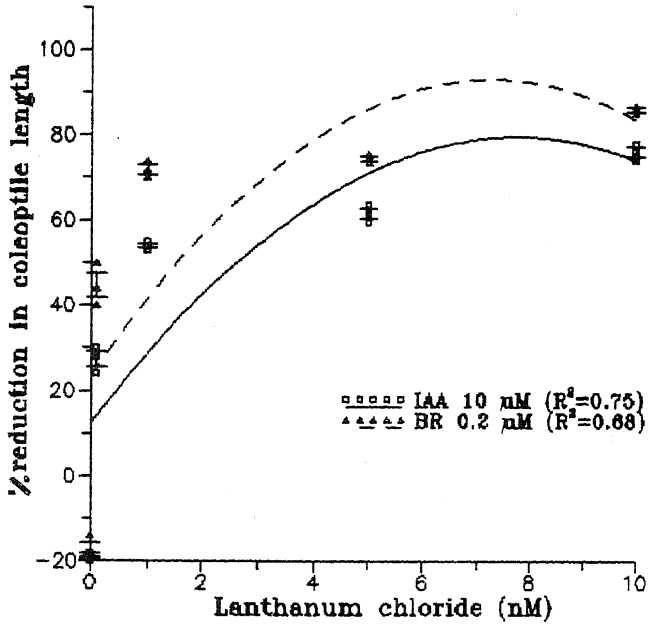

Figure 3. Effect of lanthanum chloride on IAA and BR-induced growth of wheat coleoptile segments. (Coleoptile segments were incubated in medium containing IAA (10 μM) or BR (0.2 μM) with different concentrations of $LaCl_3$. The final lengths of coleoptile segments were measured at the end of 24 h incubation in dark).

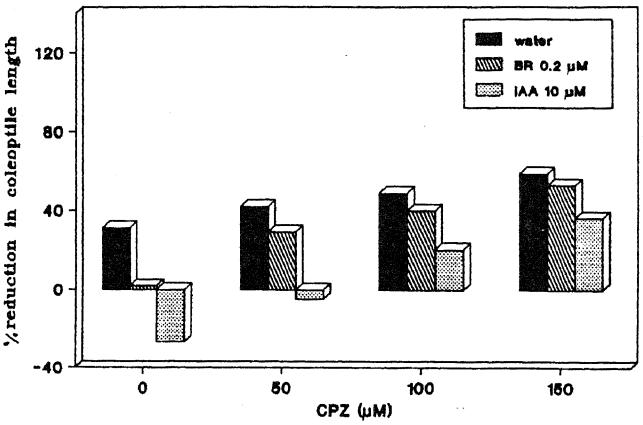

Figure 4. Effect of pretreatment of coleoptile segments with CPZ on IAA and BR-induced growth.

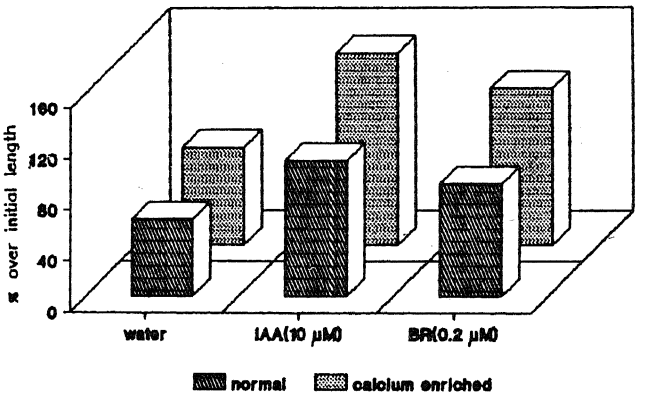

Figure 5. Effect of IAA and BR on the growth of coleoptile enriched with calcium.

medium showed 133% increase in growth. Segments pretreated with 50, 100, 150 μM of CPZ, however, showed increases of 105, 80, 64% respectively. A similar decline in response was observed when the CPZ-pretreated coleoptile segments were transferred to BR (0.2 μM) medium (Figure 4). Similar results were also obtained by pretreating coleoptiles with calcium chelating agent EGTA or calcium surface antagonist $La^{+3}Cl_3$ (data not shown).

Coleoptiles from seedlings raised in calcium-enriched medium showed significantly more elongation than coleoptile segments not enriched with calcium (Figure 5). The endogenous-free calcium in the former was nearly 27% more than the latter. Coleoptile segments enriched with calcium showed 16, 45 and 45% increase in length in control, IAA (10 μM) and BR (0.2 μM) media respectively over coleoptile segments not enriched with calcium. Under normal and enriched levels of calcium, both CPZ and EGTA were effective in reducing the elongation growth of coleoptiles induced by IAA and BR. At 50 μM CPZ and 5 mM EGTA, complete inhibition of auxin and BR-induced elongation was noticed.

Calmodulin inhibitor (CPZ) or calcium chelator (EGTA) or surface calcium antagonist ($La^{+3}Cl_3$) reduced both auxin as well as BR-induced elongation growth of coleoptiles. Coleoptiles pretreated with calcium calmodulin inhibitor – CPZ, calcium sequestering agent and calcium channel blocker significantly reduced growth in IAA or BR medium. This indicated that reducing cytoplasm-free calcium concentration and inhibiting calmodulin activity reduces IAA as well as BR-induced growth.

Coleoptile segments with high endogenous calcium concentration showed more elongation growth in the presence of BR or IAA in the medium. All the calcium and calmodulin inhibitors used were also effective in inhibiting IAA or BR-stimulated growth of coleoptile

tissue with elevated calcium levels (Table 1). The results emphasize two points—the IAA- and BR-induced growth was more in tissues having high cytosolic-free calcium concentration and calcium inhibitors were effective in reducing the hormone-induced growth in tissues with elevated calcium concentration. This may be due to altered calmodulin content in the cytoplasm. It is opined that altered calcium levels may influence calmodulin activity and thus calmodulin-mediated cellular processes[18,19]. The range of concentration of calcium inhibitors which resulted in significant reduction in growth was comparable to the inhibition of other calcium or calmodulin-mediated responses[20].

Our results therefore indicate that the action of BR which closely mimics that of auxin in causing cell elongation could also be mediated by the release of calcium with the involvement of the calmodulin-binding protein.

Uttarkashi Earthquake. H. K. Gupta and G. D. Gupta, eds. Geological Society of India, Bangalore. 1995. xxii + 233 pp.

The Uttarkashi earthquake of 19 October 1991 was important in many ways. Firstly, this was the first earthquake of magnitude (M_s) 7.0 in the Indian domain for quite a number of years. Secondly, the casualty figure was high and the damage to dwellings excessive. The loss occurred in an already backward region of India. Thirdly, this was the first substantial earthquake in the vicinity of the Tehri dam site since the designs for the Tehri hydroelectric and irrigation project were completed in the late nineteen sixties. Fourthly, the earthquake triggered a number of accelerographs installed in the region. These records are valuable evidence in the debate about seismic hazards to the Tehri project. Fifthly, the first Indian estimate of the epicentral location for the earthquake was in error grossly. The earthquake also exposed the lack of preparedness of the civil administration for relief and succour operations.

A conference on the Uttarkashi earthquake was organized at New Delhi in November 1992. The volume under review is a compilation of 19 articles presented at the conference.

Chandrasekaran and J. Das report analyses of records from 13 US-made accelerographs that were triggered by the Uttarkashi earthquake in the Garhwal region. The maximum peak ground acceleration was 0.30 *g* and 0.29 *g* at Bhatwari and Uttarkashi respectively, the two stations closest to the epicentre. Brijesh Chandra and others in a companion article report recorded peak ground acceleration of 0.52 *g* at Uttarkashi where an Indian-made accelerograph was operating also. Both the articles present information of interest to earthquake engineers, civil engineers and architects. But there should have been a more critical examination of the data in these articles. Since they are from the same university department, cross-referencing would have been possible and it would have been useful to the readers. A question of great importance left unanswered nonchalantly is, Why did the Indian-made instruments show higher accelerations than the imported instruments at the same station?

S. Jain and S. Das analysed the accelerograms reported in the above-mentioned article by Chandrasekaran and Das to assess the provisions of the Code IS 1893: 1984 for design of earthquake-resistant structures in different parts of India. It may be recalled that India has been divided into zones I to V in the code. Maximum attention has to be paid in design of structures for parts of India assigned to zone V. The authors conclude that provisions of the code are conservative for zones I to III. Thus, the cost of important structures with provisions for resistance to earthquake forces could be lowered over most parts of India if the codal provisions are relaxed suitably. On the other hand, the existing provisions are not sufficiently conservative for zone IV. This is crucial because Tehri dam site has been assigned to zone IV. In simple terms, if the observation of Jain and Das is applied to Tehri dam, then it follows that the dam built for earthquake resistance according to guidelines for zone IV may be exposed to greater earthquake hazards than those for which it would have been designed. The Uttarkashi earthquake did not provide scope for assessing the codal provisions for zone V.

Two articles by Roy and Hasija deal with geodetic observations. Elevations of bench-marks between Saharanpur and Mussoorie via Dehra Dun measured in 1991 and 1992, before and after the Uttarkashi earthquake, are compared with those measured in 1974–77 in the first article. It appears that bench-marks between Dehra Dun and Mussoorie experienced subsidence of up to 7 cm between 1991 and 1992. The authors attribute the subsidence to the Uttarkashi earthquake. But this conclusion is difficult to accept in the absence of supporting simulations based on the elastic dislocation theory. The bench-marks in question are located 70 to 80 km from the epicentre and the distance may be too large for the observed magnitude of subsidence. The suggestion of the authors that the bench-marks should be occupied regularly should be heeded by the authorities.

The second article deals with geodetic observations elsewhere in the Garhwal Himalaya prior to the Uttarkashi earthquake. This article is a wasted effort scientifically. The dimensions of the survey figures measured were too small. The geographic locations of the figures have been masked. Thus we are not sure about the region of investigation. The authors belong to Survey of India whose *raison d'etre* is to determine and disseminate accurate locations of points in the Indian territory. But the maps appearing in the two articles do not have latitude and longitude information.

Dattatrayam and others report analysis of digital data recorded through a seismograph at New Delhi for three aftershocks of the Uttarkashi earthquake. The estimated seismic moments are of the order of 10^{13} Nm and stress drops are in the range of 0.2 to 0.44 MPa. The authors present similar results for two earthquakes occurring 5 and 3 days prior to the Uttarkashi earthquake. They call them foreshocks. But their reported epicentres are so far from the epicentre of the main earthquake that this appellation is unacceptable. The low stress drops deserve note and further scrutiny.

There is an article by Arya entitled 'Long term measures for earthquake protection in Uttranchal Area of Uttar Pradesh, India'. The theme has been exposed by the author earlier for the Dharamsala area of Himachal Pradesh. Arya presents estimates of numbers of houses that may collapse or be damaged if an earthquake of magnitude (*sic*) of 6.5 occurs with its epicentre in one of the eight administrative districts in the hills of west Uttar Pradesh. Arya estimates that Almora and Dehra Dun districts will have maximum numbers of collapsed and damaged houses respectively. It is a pity that he did not check his predictions with the estimates of houses actually damaged or collapsed during the Uttarkashi earthquake.

The later part of the article provides sane advice for the future. Thus, all future constructions in these hill regions should have earthquake-resistant features. The additional cost in the case of the most cheaply constructed houses is estimated to be about 10% of the total cost. Arya notes that strengthing of existing houses is possible but will incur higher percentage of original cost.

Conditions in the affected region immediately after the Uttarkashi earthquake were tough. Efforts of scientists who visited the area for observations in this period deserve appreciation. Still the fact remains that the articles which describe the results of these qualitative and mildly quantitative observations are of a routine nature. Many articles contain conjectures about the origin of the earthquake. Extrapolations from surface geological obser-

vations to hypocentral depths of 10 to 12 km appear unwarranted.

Perusal of the articles of this volume collectively reveals in graphic detail the relatively low status of seismological studies in India *circa* 1991. Some mitigating factors may be cited. Lack of funds for seismological observations and research on a scale commensurate with the vast size of our country would be at the top of the list. The situation has not improved since 1991 at least in so far as seismological observations in our northern hill regions are concerned. Similarly, progress towards incorporation of earthquake-resistant features in individual houses and dwellings is abysmal. Thus the portents are clear. The death and destruction during the Uttarkashi earthquake will be repeated in all its tragic details during the next major earthquake of the Himalaya.

MEETINGS/SYMPOSIA/SEMINARS

IAMAS/IAPSO Joint Scientific Assemblies

Date: 1–9 July 1997
Place: World Congress Centre, Melbourne, Australia

Joint assemblies of the International Association of Meteorology and Atmospheric Sciences (IAMAS) and the International Association for the Physical Sciences of the Oceans (IAPSO), two of the associations constituting the International Union of the Geodesy and Geophysics (IUGG) will be held at Australia. In addition, there will be a symposium sponsored by the Tsunami Commission of the IUGG and IUGG associations.

Contact: IAMAS/IAPSO Secretariat
Convention Network
224 Rouse Street, Port Melbourne Victoria 3207
Australia
Phone: +613 9646 4122

In the pursuit of science: The 'subjective' element*

A. N. Mitra

Several facets of 'subjectivity' in science, from abstract value judgement to mundane human level interactions, are discussed vis-à-vis its traditional 'objective' image.

There is an almost instinctive perception in any unsuspecting mind that the pursuit of science is necessarily an objective exercise, intensely rational in its scope, and singularly free from any 'pre-conceived' notions. Indeed, the standard scenario of an interplay of theory versus experiment for determining the outcome of any idea in science, major or minor, is a *prima facie* evidence for this basic perception. In the language of Gerald Holton[1], this 'playground' is the so-called *contingency plane*, one in which theory (the calculus of logic and mathematics) is depicted as an ordinate, and experiment (empirical matters of fact and 'data') as the abscissa. Formally, this is called the 'inductive method', one in which a five-step process is involved, according to the physicist Fredrich Dessauer[2]. These five steps are simple, and in conformity with common sense[1,3]: (i) hypothesize a provisional statement; (ii) refine and structure the hypothesis; (iii) draw logical conclusions or 'predictions' which can stand experimental check; (iv) then check the predictions against the 'data' (experiment); (v) if both tally within experimental limits, then a warrant is available for claiming a 'universal validity' for the result.

On the face of it, this looks like an airtight procedure, with hardly any scope for intrusion of any other degree of freedom. However, a little reflection would show that such a picture is a gross oversimplification. For, one may ask, what is the nature or rather the origin of the hypothesis itself on whose basis the theorizing and experimentation were planned and executed? More specifically, what is the source of the original induction[1] or idea? It is here that an 'undefined' ingredient is suspected to have (unobtrusively) entered the fray already! This ingredient is quite distinct from the two-component (theory versus experiment) characterization of the 'induction process' introduced above. It is far more nebulous than the straight-jacket theory–experiment classification, and often 'resists' a quantitative definition. And yet it is a vital component of the structure of modern science, and has all along played a vital underlying role in the shaping of scientific theories since the Kepler–Newton days. Kepler had a twofold philosophy of the Universe (by fiat?), viz. (i) a mathematical harmony on the one hand and (ii) a central theological order on the other (no 'proof' offered here!). Newton too had his five rules[1,3], of which the first four are quite 'rational' (simplicity and economy of description; uniformity of Nature; universality (no exceptions); new hypotheses disallowed against contrary evidence). However, he had a fifth rule, not explicitly stated, concerning the very definition of a hypothesis.

Holton in his book[1] calls it the thematic component, which cannot be 'tested' in the sense of theory vs experiment, yet cannot be wished away[3]. One might then wonder if such a concept goes against the standard philosophy of Karl Popper, viz. the essential characteristic of any science is the 'falsifiability' of its theories. A possible answer is that no obvious contradiction is involved, since the Popperian criterion applies only to the structured part of the hypothesis or 'themata' in the form of a 'theory' which must face confrontation against experiment, towards eventual victory or defeat. On the other hand, the 'themata' is more like the 'spirit' or soul behind its structured form (the theory), and cannot be contained within the four walls of the laboratory. It resides in the human mind: it can reassert itself, or make a comeback in another form, or disappear from the scene altogether, all depending upon the nature of the outcome of its 'present incarnation' (the structured theory) with experiment. The point is that it is basically 'free', much like the proverbial '*die Gedanken*':

'Die Gedanken sind frei; wer kann sie erraten?
Sie fliegen vorbei; es nechliche schatten.
Kein Mann kann sie wiessen; keine Yaeger erschissen;
Es bleibeth dabei; die Gedanken sind frei.'

It is this thematic element that turns out to be a subjective concept inasmuch as it resides in the human mind with all its complex dimensions, which cannot be quantified. It is mostly concerned with a sort of 'value judgement' on the 'quality of ideas' which (by experience?) are deemed relevant for the 'understanding of nature' and those which are not. For example, past experience strongly suggests that certain attributes like 'beauty' and 'naturalness' which cannot be quantified as such (but 'felt' by the mind all the same!) have all along played a vital role in shaping the course of science, but only their sufficiently structured forms, say in the form of some well-defined principles, such as the 'principle of extremum' in the area of physical sciences, have been successfully confronted with experiment. Indeed, it is even possible to classify the thematic element somewhat more systematically into different categories in accordance with their 'performance', i.e. quantitative contact with 'data', in the contingent plane[1]. In particular, three such categories have been suggested[3,4] – principles, postulates and prejudices[4] – in accordance with the nature of successful contact with data (after suitable structuring) in descending order, and the resultant 'degree of confidence' thus generated with respect to their credibility within the scientific community. In this respect principles have undergone so many acid tests through continuous feedback from experiment that their speculative or 'subjective' aspects have by and large been forgotten, and they are now regarded as an integral part of the scientific discipline concerned. Postulates, on the other hand (though highly structured), have not quite made the grade

*This is an expa[illegible] a lecture given at NIAS on 28 Apri[illegible]. I am grateful to Dr S Ramaseshan for urging me to write it. I also express my deep appreciation to Dr R. Ramanna, Director, for the warm hospitality of the Institute.

in terms of data support (e.g. supersymmetry). These topics are spelt out in more detail elsewhere[3,4] and are not the main theme of this discussion.

The subjective element: value judgement of concepts

At the other end of the spectrum lie certain themata, termed prejudices[3,4], which, despite their strong appeal to intuition, are somewhat nebulous in character: they resist an unambiguous formulation. On the other hand, their sweep seems to be even wider if anything, and confidence in their intrinsic power (despite their nebulosity) has somehow been sustained (often strengthened) due to past experience. Some famous examples in this highly subjective category are well within the theme of this discussion so as to stand some repetition[3,4]:

(i) 'Naturalness' as a selectivity criterion (impossible to define, yet easy to feel in a given context).

(ii) 'Beauty' and 'simplicity' in physical concepts (same problem).

(iii) 'Duality' in physical sciences (can be illustrated with many examples but not more generally definable)[5].

(iv) 'Bootstrap' philosophy (somewhat akin to Mach's principle; once very popular in particle physics; coming up again in the context of modern string theory[6]).

(v) 'Shell structure' *ad infinitum* (so far only three stages have been confirmed, though, according to an unpublished theorem due to Drell, any regularity checked up to three stages is valid generally; see also ref. 7).

These examples illustrate but one aspect of subjectivity which relates to a sort of 'value judgement' in the pursuit of science, and operates mostly in the abstract plane of pure thought process. This 'noble' aspect, which may be more appropriately defined as 'natural subjectivity' (God is not neutral as between good and evil; 'beauty' vs 'ugliness'; simplicity vs complexity; and Nature seems to conform to His choice!), represents a perception which is largely the result of 'collective wisdom' of the human race acquired over a vast millennium in evolving its way of life, and in the process unearthing the secrets of Nature. And in the hands of scientists too, the manner in which this 'noble' form of subjectivity (value judgement) came into being (despite its spontaneous appeal in most individual minds) is the result of a complex feedback process involving interactions at the human level, and hence subject to all factors prone to human failings and weaknesses. They often relate to various techniques of 'persuasive argumentation' (to borrow a phrase from Thomas Kuhn's famous book[8], which concerns much of the discussion to follow), with an obvious connotation of 'survival of the fittest'[8]. This (second) aspect of 'subjectivity' in science (which is not always 'noble' in its working!) is the central theme for the rest of this discussion with the help of illustrative examples.

Subjectivity: the human factor

Since this field is vast in itself, it is first necessary to delineate the scope of this discussion by ruling out certain topics at the outset. Thus, we shall not be concerned with rather esoteric philosophical issues like the nature of the physical laws themselves[9]: Do these laws have an 'objective reality' in the sense of an 'out there' existence, ready to be discovered by a Newton or an Einstein, or must one be satisfied with a Bohr-like effective description, *à la* the Copenhagen interpretation (CI)? Although such questions have always retained their time-honoured philosophical significance, their renewed interest in recent times owes its origin to fresh efforts directed towards bridging the conceptual gap between the CI and a formal understanding of some famous paradoxes through the strengthening of their conceptual foundations, with extensive reviews both technical[10] and non-technical[6] available in the literature. At the moment the upshot of all this highly intellectual exercise seems to be that while the CI, thus strengthened[10], is in a better position to take on its critics, the operative value of the new machinery in terms of a capacity to predict new observable phenomena is quite limited[11]. Nor should we be unduly exercised over a proper definition of science *vis-à-vis* pseudo-science[12], since any attempt to provide a sharp distinction is fraught with serious ambiguities[12], and instead take a pragmatic, matter-of-fact view in this regard. Instead, we shall find it more relevant to our chosen theme of 'human subjectivity' to focus on the attitudes of scientists[8] within their own community in the matter of implementing the time-honoured theory–experiment confrontation in actual practice. To that end we shall begin with recalling, again at the cost of some repetition[3], the salient points of Kuhn's thesis[8] before going on to discuss some specific examples.

Kuhn's thesis: the arbitrary element

The evolution of science is a very complex process wherein its history is not a mere collection or catalogue of facts, theories and methods. Indeed, there exist many *inter se* contradictions in them, and only a directed stream emerges at the end after 'resolving' such contradictions. It is only such 'predigested' material at the hands of the chronicler of science that goes into the textbooks. This resolution is admittedly a democratic process in the usual sense of the term, and it is here that there is a catch! How about those ideas, theories (and even experiments) that did not make the grade? Indeed, it is entirely possible that there could well have been many good points about them, but somehow they got lost out in the race, not always because they got rejected by experiment (or superior experiment), but often because they never got a chance to come up to that stage! Perhaps their theories did not have strong enough godfathers (or willing listeners) for 'marketing' them. One must hasten to add that this is by and large a fair game, but the main point of emphasis (and not infrequent concern) is that in this complex process of evolution there is a fierce element of competition (often bordering on rivalry) in which the 'fittest' of ideas is given the best chance to survive. And the definition of 'fittest' is not always reassuring, even though a minimum criterion is one of maximum internal consistency plus fits to the data. Now suppose there are more than one such candidates, all conforming to these minimum criteria: Which one should be chosen? The question is not necessarily as hypothetical as it sounds, especially if such theories are proposed at some 'branching-off' stage (or cross-roads?) in the process of evolution of the science concerned. In such cases the 'lucky one' often gets chosen in an apparently arbitrary fashion, to the detriment of the others with equal *a priori* claims. True, such a choice involves a

broad consensus within the community; yet it implies a preselection[8] at the current state of the art (not waiting for more discriminating criteria at a later date). Such a process, by its very nature, is a highly subjective exercise, and gives science a very different image from that of an 'objective pursuit' of truth.

The essential point here is that the inadequacy of methodology[8] introduces an arbitrary element into the field in the course of its evolution, through a continual competition between a number of distinct views of Nature, each partially compatible with experiment. How did this come about? Somewhere along the line a particular 'belief structure' got espoused by the community[8], to the detriment of the other claimants (the arbitrary element), due to personal or historical coincidences. A sort of spontaneous symmetry breaking occurred in the branching process wherein a particular branch has been followed[6,8]. If the methodology were more perfect, other competing ideas would perhaps have had a better chance. However, taking things as they occurred one must say that the 'chosen belief branch' at a crucial turning point in history would get strengthened with time due to its pursuit by a large and committed band of well-trained workers who have learned to work within well-defined 'conceptual boxes'[8], but somehow were not encouraged to think beyond that particular discipline. This is what constitutes normal science, whose constraints strongly inhibit any novelty that clashes with its basic tenets. This may often be broken by an 'outsider' to the field who probably 'sees' more than such constrained workers (a pointer to the benefits of interdisciplinary research?).

And yet, even within the precincts of normal science, there exists an inherent 'governor mechanism'[3] which eventually comes to the rescue, and prevents an indefinite suppression of novelty. For there appear fresh contradictions – 'anomalies' – when a normal problem fails to respond to standard rules and procedures, leading to a paradigm shift[8] – a new set of commitments or rules[3,8]. Yet the fact remains that normal science is a rather conservative process of accretion of knowledge which does not as a routine aim at novelties of fact or of theory. It likes to remain quite smug in its 'understanding' of Nature in terms of its stated rules and procedures, howsoever imperfect or inadequate they may look to its own eyes. It is only when it (normal science) is 'pushed to the corner', so to say, due to the appearance of new and unsuspected phenomena, that it feels helpless against the onslaught of fresh ideas which have a potential to lead to new theories which may even be radical.

Subjectivity: the community and the establishment

Kuhn's thesis, as summarized above, brings out the nature of subjectivity in science as seen through its actual working. There is a strong 'directional element' in the *personality* that is normal science. Within this scenario, the 'objective' aspect of science is merely confined to laboratory investigations, while the dominant role is played by its 'subjective' partner, which offers a rather 'chauvinistic' view of science as a whole, one in which the survival of the fittest is the order of the day. True, it is the laboratory investigations that provide the basic strength to its practitioners to 'fight for survival'; yet a better measure of their power lies in their debating skill, or in Kuhn's words, in their capacity for 'persuasive argumentation'[8], which is probably the dominant factor that determines their 'standing' in the scientific community, while the objective part (laboratory investigation) remains largely in the background. In this dual scenario, science appears as an organized structure governed by the establishment within the community, much like in a 'democratic socio-political entity', where the final arbiter is the 'assent of the community'[8]. Nevertheless, the establishment has its own authority which 'determines' the direction of science, despite the existence of occasional 'antiestablishment' or dissident groups within the community that are at best 'tolerated' in the sense of being 'allowed' to publish their own ideas in journals which in turn are controlled by the former. However, one cannot be too sure even on such matters, what with the information explosion on 'ideas' leading to a proliferation of 'publication aspirants', who must be kept in 'reasonable check'. In this respect the prospects of publication are better ensured with 'proximity to establishment' than through the freelance efforts of an obscure worker. As further evidence of 'centralization' around the establishment in the high-tech atmosphere of today's science, yesterday's culture of individual (small-scale) scientific enterprise is gradually yielding place to a more organized form of collective (large-scale) science, with thousand members not uncommon in an experimental team. The most recent example of such team work is provided by the spectacular manner in which the CDF and D-ZERO groups have finally 'zeroed in' on the elusive TEE quark[13].

Now while such 'big science' is by and large inevitable as well as beneficial for the planning and execution of a major project in the experimental field, it is not equally obvious that the same is also true in the *theoretical* domain, where too much 'direction' may well prove counterproductive. A topical example is provided by the amount of organized effort by theoreticians in the early eighties (under the aegis of some important centres) in predicting a finite lifetime for proton decay within the limits of experimental measurability. These limits were variously estimated by methods which paid due regard to the parameters of the (high-profile) 'high-energy' dimension of the problem (grand unification theory), without a matching concern for the (mundane) 'low-energy' (hadronic matrix element) part, which required a much greater effort to produce a physically reliable figure, even though the measured value, if any, could not possibly distinguish between the two components. An independent estimate, one in which greater attention had been paid to the hadronic part, produced a value which was more than hundred times larger than most of the above (one-sided) estimates, a limit that had not been violated by the then available data[14], but coming as it did from an obscure source far away from the (theoretical) establishment, this finding was largely ignored in the literature. This result was *not* intended to claim that the GUT theory could still be valid – perhaps not – yet it seemed to be rejected for the wrong reason. (Other examples of 'subjective' decisions arrived at prematurely by consensus are given further below.) A related trend in the same context which brings out yet another dimension of subjectivity (by way of wishing to 'conform' to the 'views' of the establishment) was also discernable around the same time, in the anxiety of certain experimental groups to appear to agree with the prediction of 'faster' rates (10^{31} years) prevalent at that time[14].

The analogy with the sociopolitical scenario could indeed be pushed further if science were to be pursued under one (world) organization, in keeping with its supposedly common (international) standard. In its actual working, however, the pursuit of science is heavily circumscribed by the local and regional environments of the scientists themselves, and this often constrains their relative opportunities *vis-à-vis* their more fortunate counterparts residing in more visible centres of scientific power. This circumstance, in turn, brings in further 'asymmetries' in the overall scientific culture, and adds yet another dimension to the 'subjectivity' factor, one governed by the *actual* (not just by analogy!) sociopolitical environments of the workers themselves.

Subjectivity: theory vs experiment

Even without pursuing the sociopolitical analogy any further, the subjective nature of the actual working of science may be brought out with some specific instances of its impact on a global scale. One example was cited just above in the context of proton decay, but it need not (indeed, should not) give the impression that subjectivity is necessarily 'bad' for the growth of science on a global scale, despite the 'local' suffering of individual workers. Yet the examples are quite instructive insofar as they help in exploding the myth about the so-called objectivity in science. In a recent book[15], Collins and Pinch have highlighted some famous and not-so-famous instances of how the subjectivity factor has prevented unwarranted fluctuations in the overall stability of basically 'correct' premises of science, when it is remembered that science is merely the 'art of the possible'[16] and does by no means aim at discovering the absolute 'truth' (which is at best an asymptotic concept not accessible via 'finite efforts'). This is not to deny the need for time evolution of even the most fundamental concepts of science (did not relativity and quantum theory eventually replace the classical Euclid–Newton concepts?), but the time scale for such evolutions is the result of a very complex feedback within the scientific community and cannot be determined on the basis of any insufficient efforts, howsoever reliable, from a few individual workers without a thorough debate within the community on their wider implications.

The first example concerns the famous expedition of Eddington in 1919 to verify Einstein's general relativity. Even a cursory perusal of the Collins–Pinch account would convince anyone that the 'raw data' were hardly discriminatory as between the Newton and the Einstein predictions (which differed by half). Yet a conscious value judgement had to be introduced by Eddington (with active support from the Astronomer–Royal) to decide in favour of the Einstein (not Newton) prediction. At the hands of a lesser mortal such a 'doctoring' of data would either be ignored or (if, the worker has a good reputation) provoke violent protests. Indeed, in the present age such 'poor' data would simply be 'unacceptable' in the first place, a recent example being the 'monopole' event of Cabrera[17]. A more substantial evidence of the demands of modern rigour in the processing of data is provided by the 'processing time' taken by the CDF team work before finally deciding to publish their results[13], even though the crucial nature of their findings (for which the entire community had been waiting with bated breath) would have ensured a ready acceptance. A greater boldness (and daring!) had been shown by Carlo Rubbia a decade earlier, when, as leader of the UA2 team, he had decided to publish their findings somewhat in advance of the final results, for which the entire high-energy community had been waiting anxiously.

However, Eddington's expedition was in the Rutherford era when science and its practitioners used to be regarded with far greater awe and reverence than is the case today. And, with his formidable standing within the scientific community, he was able to push through his 'interpretation' successfully, as the circumstantial evidence was overwhelmingly in its favour, though not necessarily on the basis of the actual data obtained from the expedition. The important lesson from this episode is that an experimental 'confirmation' of a theory in the standard orthodox fashion – the bedrock of 'objectivity' in science – is not always relevant for 'belief in the theory'! In retrospect, Eddington turned out to be right, but for a 'wrong' reason, since it would not have mattered much what the data showed. On the other hand, his deep insights in physics, howsoever buttressed by his high prestige, had their own limitations as were tellingly confirmed by his own student Chandrasekhar's subsequent 'victory' over the Professor's (superior?) judgement on the now famous *Chandrasekhar limit*. And yet the damage that the Professor's initial verdict had caused to his student's career in the interim period is a matter for history[18]. Lesson? Personal authority as an instrument of subjectivity must not be pushed too far, since its credibility is not unlimited! Failure of 'institutional authority' is already illustrated (see above) by the failure of proton decay within the time limits set by the grand unification theory.

Yet subjectivity has been known to 'pay' if combined with a right 'dose' of intuition together with establishment's support, in both of which the actual 'experimental' evidence, especially in the short run, often plays a marginal role. Thus, in the famous 'experimental' debate between Pouchet and Pasteur[15] on the origin of life, Pasteur was against the spontaneous generation theory advocated by Pouchet. Although Pouchet's experiments seemed to support his theory, Pasteur would invariably come up with some 'catch' in the experimental material and/or set-up. He even 'discarded' some of his own experiments which showed a bias for 'spontaneous generation', relying more on his intuitive perceptions than on the actual observations. And he was supported by the Paris-based Academie des Sciences – the establishment – even though the latter's reasons were anything but objective. That Pasteur was upheld by later, more precise, results is an entirely different matter.

A similar incident of more recent origin concerns Fairbank's (an experimental physicist of considerable reputation) 'discovery of the quark'[19], a result which was hotly disputed by Morpurgo, who was so sure of his ground that he even ventured to suggest that it was an artefact of the 'mode of observation'[20]! Finally, at the Rochester Conference of 1960, during the heydays of the V–A theory, Feynmann simply refused to believe that the theory could be wrong, even though some helium-6 data were 'strongly supporting' the scalar-tensor theory. Such examples can be multiplied.

All these examples illustrate the more 'noble' aspects of subjectivity that relate to a 'value judgement' in which deep intuition plays a vital role.

Conclusion

In the foregoing we have tried to depict several facets of subjectivity, from value judgement to human interactions, that are employed in the actual practice of science. While the traditional picture of science is one of 'strictly objective' interplay of theory and experiment within the rules of the game, subjectivity enters in a vital way as a sort of value judgement in the worker's own perceptions of the same. This 'abstract' aspect of subjectivity is an intensely personal perception which remains hidden from view but may be reflected in his choice of problems and the tenor of his writings. The more visible aspect of subjectivity, on the other hand, enters through human interaction, wherein science is a part of the community's larger concerns, and hence is subject to all standard types of socioeconomic and sociopolitical pressures. Sandwiched between these dominantly 'subjective' elements, the 'objective' part of his practice of science is more or less a routine affair, appearing essentially as an end product of his investigation, while the vital decisions are controlled by the former.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

COVER. *Top*: A diagrammatic representation of the human immunodeficiency virus (HIV). The central core of the virus contains the genetic information that the virus needs to reproduce itself. The highly complex egg-shaped projections covering the surface of the virus allow it to attack CD4 lymphocytes in a unique fashion. *Below left*: The retina of a patient with AIDS: the retina is usually pink and blood vessels can be seen running over its surface. The white patches represent infection with cytomegalovirus. *Below right*: The eye of the same patient a week later, showing how rapidly the infection can spread when T cells are unavailable for defence. See Special Section. [Reproduced with permission from *The Body at War* by John M. Dwyer, Publishers Allen and Unwin.]

Single copy of this issue, Rs 150/US $20.

In this issue

AIDS

Almost fifteen years have passed since the disease AIDS surfaced in the United States. This immune deficiency state which rendered patients susceptible to opportunistic infections was soon recognized to be a sexually transmitted disease, with the causative agent being a retrovirus. Originally thought to be limited to homosexual populations, AIDS was soon to assume the dimensions of a major public health problem when heterosexual transmission and infection via blood transfusions and contaminated syringes in drug addicts were established. There is no satisfactory treatment for AIDS and approaches to limiting the spread of the human immunodeficiency virus (HIV) are still to take hold. The magnitude of the AIDS problem in India appears to be relatively small at present; malaria, tuberculosis and diarrhoeal diseases may still be more widespread. However, the dangers of underestimating an insidious enemy are all too clear. A special section in this issue, edited by David Bloom highlights the complexity of the problems involved in addressing the growing AIDS epidemic.

P. Balaram

Fifty years after a landmark

The melting of ice and the loss of magnetism by iron on heating are two examples of what physicists call phase transitions. In the second example, the order becomes zero continuously at a critical temperature. Various approximate models for this behaviour have been proposed, starting with van der Waals in the last century. On close examination, they proved inconsistent, both with the best experiments and internally. Fifty years ago, Lars Onsager found an exact mathematical solution of one model of a phase transition — a brilliant discovery which changed the course of the subject. This historic event, the prelude to it and its aftermath are recounted for our readers by S. M. Bhattacharjee and A. Khare (**page 816**).

Pioneers of ozone study bag chemistry Nobel

The 1995 Nobel prize in chemistry has been awarded jointly to Paul J. Crutzen, Department of Atmospheric Chemistry and Biogeochemistry, Max-Planck-Institute for Chemistry, Mainz, Germany; Mario J. Molina, Department of Earth, Atmospheric and Planetary Sciences and Department of Chemistry at Massachusetts Institute of Technology, USA; and F. Sherwood Rowland, Department of Chemistry at the University of California, Irvine, USA.

The laureates are recognized for their pioneering work on the subject of formation and decomposition of ozone. Crutzen was instrumental in establishing the importance of nitrogen oxide chemistry. Rowland and Molina were the first to warn that chlorofluorocarbons (CFCs) released into the atmosphere were depleting the ozone layer. By explaining the chemical mechanisms that threaten to destroy the protective ozone screen surrounding the earth, the three scientists have contributed to our salvation from a global environmental damage that could have serious ill-effects.

The ozone layer[1-3]

Ozone, a three-atom molecule of oxygen, occurs naturally as a gas in trace amounts in the Earth's atmosphere. It is found primarily in a layer between about 12 and 50 km above the Earth's surface, in the region of the atmosphere called the stratosphere. The ozone layer is thin, fragile and almost invisible. Yet it plays an exceptionally fundamental role in determining the habitability of the Earth.

A one per cent decrease in ozone allows a two per cent increase in UV radiation that reaches the Earth. Effects from increased UV radiation include an increased risk of skin cancer, cataracts and immune deficiencies in humans, as well as damage to crops and the plankton that supports marine life. While the stratospheric ozone plays a beneficial role, the surface-level tropospheric ozone is one of the most harmful pollutants, damaging plants and humans. The tropospheric ozone is produced through smog type of reactions[4], a familiar problem in the atmosphere of many cities around the world.

The first qualitative photochemical theory for the formation and decomposition of ozone in the atmosphere was formulated by Sidney Chapman[5] in 1930. According to this theory, ozone is produced in the middle and upper atmosphere through dissociation of molecular oxygen by sunlight; the free oxygen atoms combine with other O_2 molecules to form ozone.

$$O_2 + UV(\lambda < 242\ nm) \rightarrow O + O$$
$$O + O_2 + M \rightarrow O_3 + M,$$

where M is a third body required to carry away the energy released in the combination reaction. The triple collision is rare at very high levels (above 60 km), because there are so few molecules. Thus, there is almost no ozone above 60 km. On the other hand, there is almost no atomic oxygen, O, below approximately 16 km, so the formation of ozone is unlikely there, too. These are the reasons most of the ozone is found in the stratosphere.

Early warnings

Chapman's theory, however, showed appreciable deviations from measurements. The calculated ozone contents were considerably higher than the observed ones. To account for this, Bates and Nicolet[6] drew attention to the role played by H, OH and HO_2 (products of UV photolysis of water vapour) in the catalytic reduction of odd oxygen above 60 km. But the calculations again showed very large concentrations of ozone than the observations.

Paul Crutzen[7] in 1970 suggested that additional important processes must be taken into account in order to correctly describe the photochemistry of the atmospheric ozone. Crutzen uncovered an important aspect that nitrogen chemistry accounts for a significant fraction of ozone loss in the natural atmosphere, particularly above 25 km.

$$NO + O_3 \rightarrow NO_2 + O_2$$
$$NO_2 + O \rightarrow NO + O_2$$
$$\text{net: } O_3 + O \rightarrow 2O_2.$$

Using available satellite data, Crutzen provided a much more quantitative

Crutzen was born in 1933 in Amsterdam. He obtained his doctorate in Meteorology in 1973 from Stockholm University. He is a member of the Royal Swedish Academy of Sciences, the Royal Swedish Academy of Engineering Sciences and Academia Europaea.

understanding of the sources of NO_x via N_2O oxidation

$$N_2O + O \rightarrow 2\ NO.$$

The primary sources of N_2O include oceans, combustion of fossil fuels, fertilized agriculture fields, tropical and subtropical forests and woodlands. N_2O diffuses upwards from troposphere to the stratosphere to give NO which in turn reacts with ozone. The connection demonstrated by Crutzen[8] between tropical biomass burning and the ozone concentration is one of the motives for the recent rapid development of research on global biogeochemical cycles.

Johnston[9] rediscovered the NO_x–O_3 sequence and made a connection to supersonic transport emissions. Supersonic civil aircraft can fly across the ocean at supersonic speeds, but cannot fly across land because of the sonic boom noise. These aircrafts would be capable of releasing nitrogen oxides right in the middle of the ozone layer at the altitudes of 20 km. Crutzen's and Johnston's work gave rise to a very intensive debate among researchers as well as among technologists and decision-makers. Since then, several multidimensional models[10] have been developed to assess the potential environmental effects of aircraft operations in the stratosphere. But it must be pointed out that opposition to the 1970s supersonic fleet came primarily because of the very high development cost and not just the NO_x engine emissions.

The CFC affair

The next vital step towards a deeper understanding of ozone chemistry was in 1974, when Rowland[11] and his then postdoc, Molina, established the possibility of major stratospheric ozone depletion from CFCs. During the early seventies, CFCs were used as tracers in the troposphere because of their lack of reactivity. According to 'Rowland–Molina hypothesis' as it is now often described, the release of atomic chlorine from the solar UV photolysis of CFCs triggers catalytic chain reaction that causes significant depletion of stratospheric ozone layer.

CFCs were invented in 1928 as safe alternatives to ammonia and sulphur dioxide refrigerants. Since then the uses of CFCs have been expanded to include aerosol propellants, air conditioning, refrigerants, foam-blowing agents, and as solvents in electronic industries[12]. They are volatile, nonflammable, noncorrosive, nonexplosive, low toxic and chemically inert, and hence safe to work with. The very lack of chemical reactivity that makes CFCs commercially useful also allows them to persist for many decades in the Earth's atmosphere. The most important CFCs[13] for ozone depletion are: trichlorofluoromethane - $CFCl_3$ (CFC-11), dichlorodifluoromethane - CF_2Cl_2 (CFC-12), 1, 1, 2 trichlorotrifluoroethane - $CF_2ClCFCl_2$ (CFC-113) and carbon tetrachloride (CCl_4).

Rowland and Molina realized that the chemically inert CFCs could be

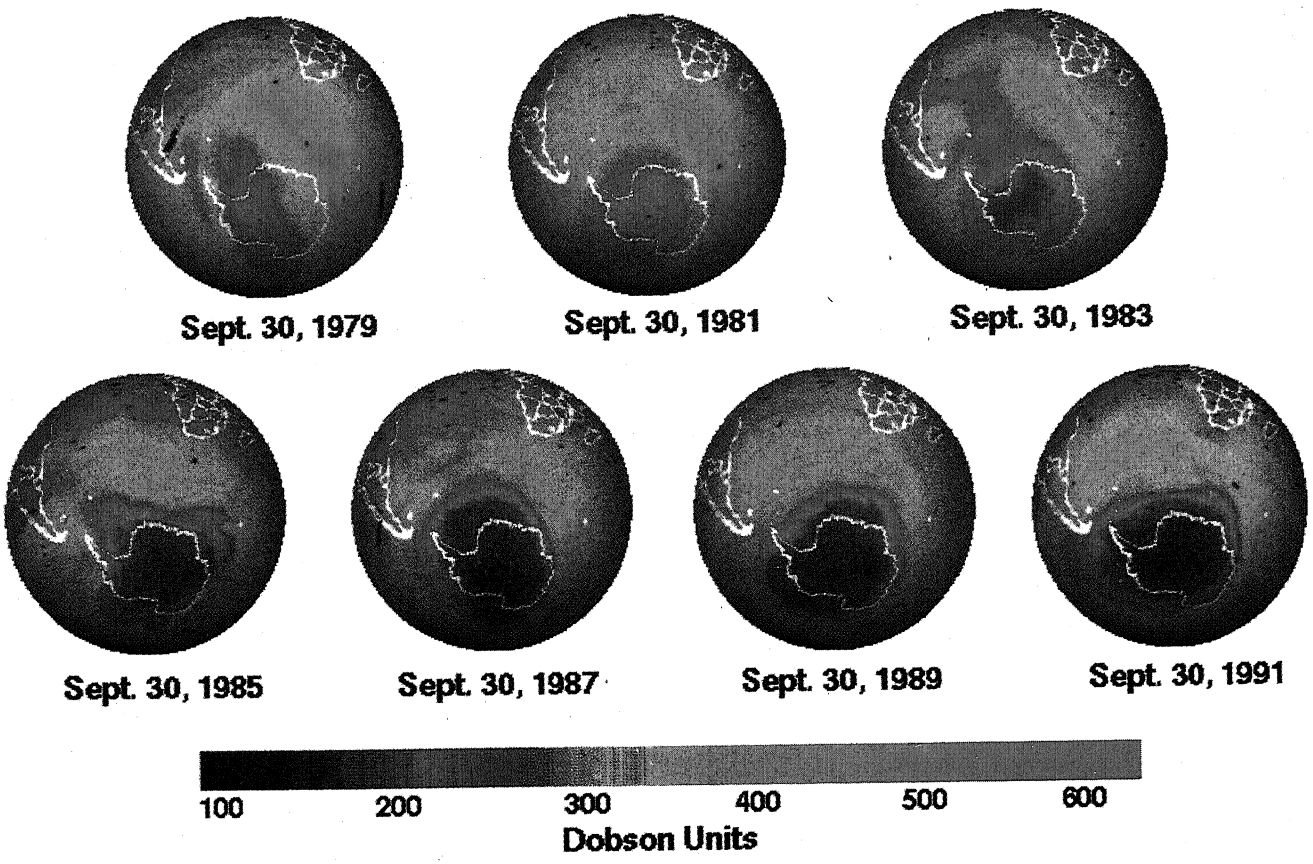

Figure 1. Progressive thinning of ozone layer as revealed by TOMS data.

transported to the stratosphere and decomposed by solar UV radiation.

$$CCl_2F_2 + UV(\lambda < 220 \text{ nm}) \rightarrow Cl + CClF_2.$$

After they are photolysed, most of the chlorine eventually ends up as hydrogen chloride, HCl, or chlorine nitrate, $ClONO_2$. These are called reservoir species. Alternatively, the chlorine atoms released could participate in the catalytic removal of ozone. The simplest mechanism suggested by Rowland and Molina is

$$Cl + O_3 \rightarrow ClO + O_2$$
$$ClO + O \rightarrow Cl + O_2$$
$$\text{net: } O + O_3 \rightarrow 2O_2.$$

Note that the role of chlorine atoms is that of a catalyst. Thus, an atom, once released, can participate in the O_3 removal as long as it stays in the atmosphere. The process is even more dramatic for bromine – it has no stable reservoirs; so the Br atom is always available to destroy ozone. On a per-atom basis, Br is 10–100 times as destructive as Cl. In contrast, fluorine is innocuous in the stratosphere. Most of it ends up as its reservoir – hydrogen fluoride (HF), which is extremely stable. Since chlorine and bromine radicals both cause ozone destruction, it comes as no surprise that iodine can also do so.

Hole in the ozone shield

Antarctica is the southernmost continent of the world, and literally speaking, one of the most remote places on the Earth. But here occurred the first large-scale ozone loss. Public concern was aroused in 1985 when atmospheric scientists of the British Antarctic Survey[14] announced their startling discovery of an 'ozone hole' over Halley Bay, Antarctica. Other scientists confirmed the discovery and reported that the region of ozone depletion was actually wider than the continent. These findings led to signing of a treaty in September 1987 on the protection of the ozone layer, known as Montreal Protocol, the first global environment protection agreement.

The quantitative aspects of the ozone hole, however, could not be explained by dynamical processes or by gas phase chemical reactions. In fact, atmospheric models employing the gas-phase chemistry estimated only a 1–2% loss of ozone, significantly less than what has been observed. Such findings prompted the ozone researchers to suspect that an alternative mechanism must exist that could accelerate the decomposition of ozone. As it turned out, Rowland[15] along with Solomon, Garcia and Wuebbles identified this mechanism as chemical reactions on the surface of cloud particles in the stratosphere. The clouds convert two so-called reservoir species of chlorine, HCl and $ClONO_2$, into more reactive chlorine (Cl_2) and hypochlorous acid (HOCl):

$$HCl + ClONO_2 \rightarrow HNO_3 + Cl_2$$
$$H_2O + ClONO_2 \rightarrow HNO_3 + HOCl.$$

The nitric acid that is produced sticks to cloud particles whereas the Cl_2 and HOCl fly off into the gas phase. Further, Crutzen[16] and Arnold emphasized that the clouds absorb nitrogen oxides and thus it allows the abnormally high chlorine to persist.

Rowland was born in Delaware, USA in 1927. He earned his B S degree from Ohio Wesleyan University and his M S degree from University of Chicago. In 1952, Rowland received his Ph D from the University of Chicago and taught at Princeton University and the University of Kansas before going to Irvine in 1964 as founding Chairman of its chemistry department. Before the publication of the Rowland–Molina papers on CFC problem, his research centered on the chemical reactions of radioactive isotopes. Currently, Rowland is Emeritus Professor in the University of California and he is also Foreign Secretary of the US National Academy of Sciences.

$$NO_2 + NO_3 + M \rightarrow N_2O_5 + M$$
$$N_2O_5 + H_2O \rightarrow 2HNO_3.$$

That is, the conversion blocks the following reaction

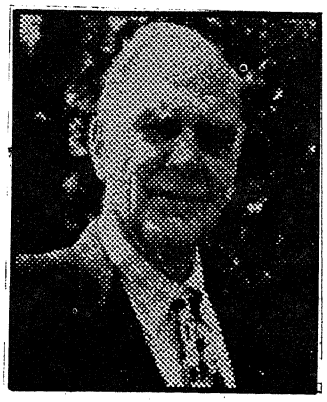
$$ClO + NO_2 \rightarrow ClONO_2.$$

As a consequence of these studies, an exciting new branch of atmospheric chemistry has emerged: 'heterogeneous' chemical reactions on particle surfaces.

In the stratosphere, a stream of air known as polar vortex circles Antarctica in winter. Air trapped within this vortex becomes extremely cold during the polar night. Temperatures drop low enough to form clouds even in the very dry stratosphere. Particles of nitric acid trihydrate (type I polar stratospheric clouds (PSCs)) first condense at about 193 K; water ice particles (type II clouds) form when the temperature falls still lower, to about 187 K. These clouds freeze-out water vapour (dehumidification) and remove nitrogen oxides (de-nitrification) by adsorption of HNO_3 into the PSCs[17]. As mentioned earlier, the PSCs provide a reaction surface for transferring inactive chlorine to an active stable form ready to react once sunlight appears in the spring. The arrival of UV radiation photolyses the Cl_2 to radicals that can catalyse ozone destruction.

Several proposals have been made for the catalytic mechanism linking halogen radicals to the chemical destruction of ozone[18]. For example, McElory[19] and coworkers suggested ClO–BrO mechanism while Solomon[15] and colleagues proposed ClO–HO_2 sequence in addition to the classical catalytic couplet originally introduced by Molina and Rowland. Nevertheless, a chlorine chain[20] suggested in 1987 by Mario Molina and his wife Louisa J. Molina, involving ClO dimer formation at low temperatures followed by photolysis and thermal decomposition is now thought to account for the massive ozone destruction. The proposed mechanism follows.

$$Cl_2 + h\nu \rightarrow 2Cl$$
$$Cl + O_3 \rightarrow ClO + O_2$$
$$Cl + O_3 \rightarrow ClO + O_2$$
$$ClO + ClO + M \rightarrow ClOOCl + M$$
$$ClOOCl + h\nu \rightarrow Cl + ClOO$$
$$ClOO + M \rightarrow Cl + O_2 + M$$
$$\text{net: } 2O_3 \rightarrow 3O_2.$$



Molina[21] and coworkers also proposed a variation on this sequence in which the

photolysis of ClOOCl was replaced by thermal decomposition.

Basically, the overall effect of all these processes is to pre-condition the Antarctic stratosphere so that when sunlight returns to the stratosphere in spring two ozone molecules can be transformed into three molecules of oxygen through the above sequence of reactions. Once the spring is well-on, the Sun induces a dynamical breakdown of the stable vortex, and the 'chemical containment vessel', as it is sometimes called, is broken down and mixing of air with lower latitude occurs. PSCs evaporate and the atmosphere returns to a normal state.

Hence, in late winter, regions of ozone depletion around the pole begin to appear. Within a few weeks, the ozone hole is completely established. The hole disappears when the polar vortex finally breaks down after the spring Sun warms the air over Antarctica. Air then sweeps in from low latitudes, bringing nitrogen oxides that tie up the active chlorine and ozone that fills up the hole. The depletion first identified over Antarctica is now being observed to a lesser extent over the Arctic too, and is also much more evident at middle latitudes than has ever been predicted.

The Total Ozone Mapping Spectrometers (TOMS) aboard the NASA's Nimbus-7 spacecraft (launched on 24 October 1978) measures the total column ozone density of stratospheric ozone by observing back scattered solar UV radiation. The results of such measurements are usually presented in Dobson Units (1 DU = 2.69×10^{16} molecules of ozone cm^{-2}). Time series of TOMS images are shown in Figure 1, which illustrates the changes in total ozone over Antarctica at the beginning of every austral spring. The colour scale at the bottom shows the total ozone values in Dobson units. As a matter of fact, the roughly circular ozone hole rotates around the south pole at an offset, moving around the Antarctic continent and back to original position about once a week.

Mario Molina – the first Mexican to receive a scientific Nobel – was born in 1943 in Mexico City, Mexico. He received his Ph D in Physical Chemistry from the University of California, Berkeley. His wife Louisa is a Chinese and she is also a physical chemist. Mario is a member of the US National Academy of Sciences.

Skeptics, CFCs, and the ozone layer

When Rowland and Molina predicted in 1974 that chlorine from CFCs could chew away the ozone layer, some skeptics did not want to believe it at first. Further, the critics claimed that only small amounts of CFCs could enter the stratosphere because they are heavier than air (the molecular weight of CFC-11 (CCl_3F) is 137.5; that of air 29), adding that the chlorine is vented into the atmosphere by evaporation of sea water and eruptions of volcanoes.

Rowland made a broad attempt to confront the controversy and tackled the misconceptions concerning CFCs and ozone depletion. He argued that indoor experience with mass-dependent molecular diffusion is not applicable in the wind-driven atmosphere, in which the mixing process does not distinguish molecular masses[22]. If atmospheric gases segregate by weight, then the heavier molecules should dominate at lower altitudes. In reality, however, the relative proportions of Helium-4, Nitrogen-14, and Krypton-84 are unchanged from ground-level to about 100 km, despite the variation in molecular weight. Concerning the chlorine from sea water, it is in the form (NaCl) that is rapidly removed from the troposphere by rain. Volcanoes do eject chlorine as HCl during eruptions. But again, HCl is washed out by rain in the troposphere. Only rarely are eruptions so violent that they inject material directly into the stratosphere.

At last, the fierce debate is now over and the researchers are convinced that chlorine from CFCs is responsible for the ozone loss. Thanks to pioneering research by many researchers, among them Crutzen, Molina and Rowland, as well as Susan Solomon, James Anderson, Richard Stolarski, Ralph Cicerone and Donald Wuebbles.

Deservedly rewarded...

In recent years, Crutzen[23] has continued to make many other important contributions to the current understanding of atmospheric chemistry, both in the troposphere and stratosphere. Molina's[24] work at MIT (and University of California, Irvine and Jet Propulsion Laboratory before going to MIT) has mainly emphasized laboratory studies of heterogeneous reactions in relevance to atmospheric chemistry. Rowland's[25] work has primarily involved grab sample measurements of tropospheric gases, such as methane, hydrocarbons and halocarbons. Equally important, he urged scientists to reach beyond their subspecialities and attempt the difficult job of communicating sound science to the public.

Without a doubt, ozone researchers are all delighted and pleasantly surprised by the selection of environmental sciences for recognition by the Nobel committee. The Nobel prize to the trio of atmospheric scientists has elevated the whole area of ozone research. Indeed, it is the first Nobel prize for any environmentally related work. The Nobel committee, perhaps, is starting a trend to recognize scientists who have made fundamental contributions in applied sciences!

The 1995 Nobel Prize in Medicine: A tribute to the power of formal genetics

One of the most remarkable areas of achievements in biology during the past few decades has been the elucidation of the mechanisms that an apparently unstructured egg cell uses to transform itself into a complex-patterned multicellular organism. The first glimpse of this genetic blue-print was obtained through genetic studies with the fruit fly *Drosophila*. Fortunately, these results were obtained at a time when the recombinant DNA and molecular biological techniques were spreading like wild fire and therefore, even these esoteric genetic studies with *Drosophila* attracted the imaginations of biologists working with all kinds of organisms. Very soon the commonality of organization of all living organisms was reaffirmed and scientists could hope to decipher the genetic programme that controls development of as complex an organism as *Homo sapiens*.

Therefore, the committee for this year's coveted Nobel prize in Medicine has very rightly selected three *Drosophila* geneticists for their pioneering work on the genetic control of embryonic development and differentiation using simple but powerful tools of conventional genetic analysis. They are Edward B. Lewis of The California Institute of Technology, USA, Christianne Nüsslein-Volhard of the Max-Planck Institute for Entwicklungsbiologie, Tubingen, Germany and Eric Wieschaus of Princeton, USA. Lewis has been working with *Drosophila*, mostly by himself, for more than 50 years and published[1] a summary and analysis of the data collected by him over many years in his well-known *Nature* paper in 1978; Nüsslein-Volhard and Wieschaus published[2] their seminal paper, also in *Nature*, in 1980 when both were at the EMBO Laboratory in Heidelberg, Germany. These two papers have changed the course of contemporary biology in more than one way by allowing a new look at the transformation of a seemingly structureless egg into a complex, patterned and organized organism. The concepts generated in these papers have found very wide applications in studies dealing not only with animals but plants as well. It is remarkable indeed, that these two papers were based on simple methodologies of 'pure' or formal genetics with no 'sophisticated' or 'advanced' molecular biological techniques being employed. As is the wont of geneticists, they simply obtained a large number of mutations, selected those that affected early development, mapped the mutations on linkage maps and characterized the consequences of either individual mutations or specific combinations of the different mutations on the developmental phenotype of the individual. The only 'advanced' analytical techniques employed by these scientists were scanning electron and/or dark-field microscopy! It was the systematic analysis and a foresight in rationalization of the phenotypic effects of the various mutant genes that led them to formulate general principles of Nobel prize-winning consequence.

Study of embryonic development has fascinated biologists for a long time. Curiosity to know how a single-celled egg develops into a complex organism led to the growth of the whole field of Embryology to describe the morphological and anatomical changes taking place in a developing embryo. In biology it is often necessary to examine the abnormal so that the normal may be understood. Thus a conventional experimental embryological approach to the study of a complex process has been to disrupt one step in the chain of events and follow its consequence. This path was followed by generations of eminent embryologists during this century and their efforts did help in providing some

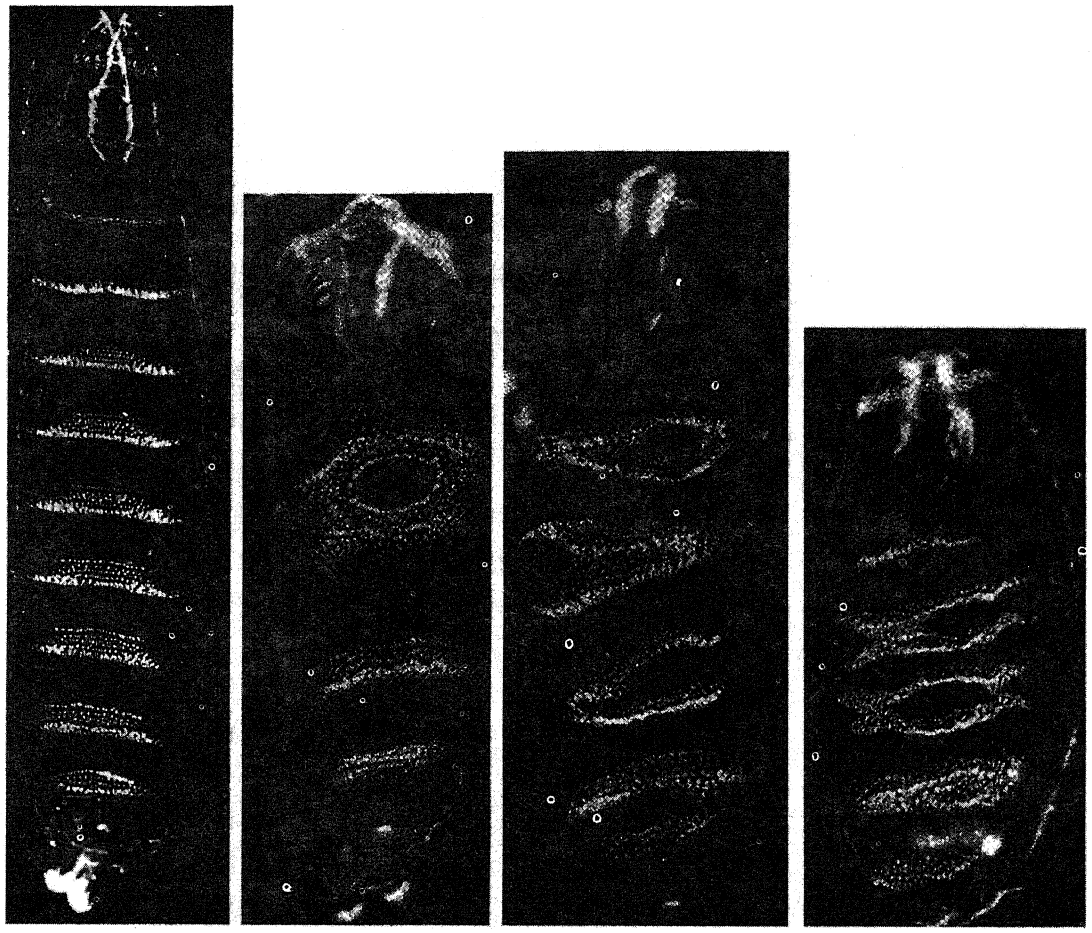

Figure 1. Examples of disruptions in normal segmentation of late *Drosophila melanogaster* embryos due to mutations in some of the segmentation genes identified by Nüsslein-Volhard and Wieschaus: the first panel shows the segmentation pattern in a normal late embryo; the second is an embryo mutant for the *krüppel* gap gene (with the prothoracic to 5th abdominal segments missing), the third one is mutant for the *paired* pair-rule gene (with the posterior compartment of all odd-numbered and the anterior compartment of all even numbered segments missing) while the last one has a mutation at the *engrailed* segment-polarity gene (with posterior compartments being affected). Identification of such defects in segment patterns in mutant embryos led the scientists to interpret the functions of the wild-type genes in normal pattern regulation.

cause–effects relationships in the complex events taking place during embryonic development. However, none of these approaches could address the central question of what molecules actually caused a particular cell in the embryo to decide or to know that it belongs to say head or tail region of the future animal or the leaf or root of the plant. With the growing realization that like all other things in living organisms, the development was also under genetic control, a geneticist would approach this issue by inducing random mutations in genes and identifying, not only the gene that has mutated but also the consequence of that mutation on the phenotype of the individual. It is this approach that led the three Nobel-prize winning scientists to provide the first insights into the complex signalling and regulatory events that 'tell' the undifferentiated cells to be committed to and follow a particular path of differentiation during early embryonic development.

To appreciate and understand the significance of these two papers[1,2], we need to briefly look at the way the *Drosophila* embryo develops (it is interesting to note that the basics of *Drosophila* embryology were properly understood only because of these and other subsequent papers, yet to understand these papers *today* we first need to look at what was historically learnt later: this highlights the farsighted intuition of these scientists as well as the power of genetic analysis). Unlike any other well-studied case of embryonic development, the *Drosophila* embryo follows a very unusual pattern of cleavage divisions during which only the nucleus divides repeatedly without any cell division; this results in a syncitial blastoderm stage which quickly cellularizes. This is followed by the demarcation, along the anteroposterior axis, of the repeating units of a defined number of body segments (parasegments) with the visible segment boundary bisecting each parasegment. As a result, each anatomical segment includes the posterior half and the anterior half of consecutive parasegments. Depending upon the antero-posterior and dorso-ventral coordinates, cells in each half (compartment) of the segment are committed to generate specific adult structures. A variety of genetic studies had established that even at the syncitial blastoderm stage, much before the morpho-

logical segments become apparent, each nucleus 'knows' its location in the embryo and also what its 'fate' is going to be when the cells begin to differentiate. The time gap between this 'commitment' and 'differentiation' can in fact be several days long. The basic question of how the nuclei in the syncitial blastoderm of *Drosophila* 'know' their location and their fate was addressed through genetic studies.

Although Lewis worked much earlier than Nüsslein-Volhard and Wieschaus, the genes that Lewis studied are called upon their duties later in embryonic development than the sets of genes described by the other two. Nüsslein-Volhard and Wieschaus argued that genes that control early embryonic development (and thus affect the critical determination events), if mutated, should cause malformed embryos and therefore be embryonic lethal. Therefore, they generated, through conventional mutagenesis procedures, a large number of random mutations in *Drosophila* genome and selected those that led to death of embryos. A simple microscopic examination of these dead embryos helped them determine the defect in the normal developmental pattern and thereby decipher the role of the mutated gene in the process (see Figure 1). In summary, Nüsslein-Volhard and Wieschaus showed that three sets of genes are sequentially activated after fertilization: i) the 'gap' genes define by their expression three major domains (anterior, middle and posterior) along the length of the embryo so that a mutation in any of these genes resulted in the loss of a contiguous series of structures along the antero-posterior axis; ii) the 'pair-rule' genes, working after the 'gap' genes, commit the nuclei to one of the 14 repeating segments along the length of the syncitial blastoderm: these were called 'pair-rule' genes since they seemed to work in alternate segments and a mutation in any of these genes caused alternate, odd or even-numbered, segments to be defective, and iii) the 'segment-polarity' genes which finally commit a blastoderm nucleus to the anterior or to the posterior compartment of a given body segment so that a mutation in any of these genes disrupts the polarity in each segment. These three sets of genes thus were shown to 'instruct' the blastoderm nuclei their polar co-ordinates and thereby define segmentation of the body, much before we can actually see it.

A parallel development around this time was the identification, again through mutational analysis, of a number of genes that were active during the period of oogenesis in the mother and whose products were later shown to be very orderly localized in the egg cell; the products of these maternally acting genes behaved like the classical morphogens to directly activate the different gap genes in different domains of the fertilized egg and through them the later acting pair-rule and segment polarity gene cascades.

The genetic system elucidated by Lewis comes into play after the above three sets of genes have carried out their work. Lewis worked with a very interesting family of mutations, designated by *Drosophila* geneticists as the 'Bithorax-complex' (BX-C): this name was given since the flies that carried such mutations typically showed duplication of the thoracic region (see Figure 2). Such mutations belong to an interesting class, the homeotic mutations, a term coined by W. Bateson[3] in 1894 for malformations that substituted the pattern of one body region for another. Very early in the growth of *Drosophila* genetics, a number of homeotic mutations (e. g. the *bithorax, aristapedia, proboscipedia*) were identified. The existence of homeotic mutations signified that certain genes 'tell' the cells at some stage of development as to what they are destined to become and if, as a result of mutation, these genes gave a wrong instruction to a cell, the cell develops a different structure at a wrong place (the homeotic transformation). Thus such mutations provide an unique opportunity to ask what these genes 'tell' the cell and at what time. Lewis approached this goal by analysing the large number of mutations that mapped to this locus and which transformed a thoracic or an abdominal segment of the fly into another in a complex but predictable fashion. He had earlier shown that this locus is a complex locus being composed of several discrete genetic units (hence these individual units were initially termed 'pseudoalleles') which were very closely linked but each had a distinctive effect on the phenotype of thoracic and the abdominal segments. He summarized an enormous wealth of his own experimental data in the 1978

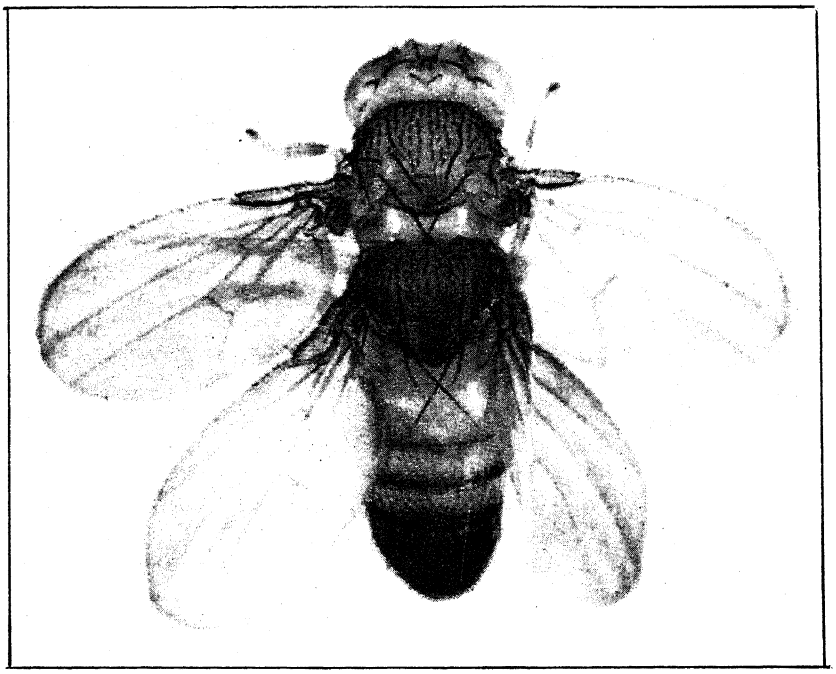

Figure 2. A typical four-winged fly generated in Lewis experiments when certain *bithorax* mutant alleles were brought together in heterozygous combinations: such a combination of the mutant alleles lead to a homeotic transformation of the meta-thorax into meso-thorax so that the normally reduced second pair of wings (the halters) in the meta-thoracic segment now develop into full wings like those in the meso-thoracic segment.

review published in *Nature*[1] to show that the different genetic elements comprising the BX-C control most of the body plan of the fly. He showed that a chromosome that had lost almost whole of the BX-C resulted in an embryo with all its body segments being similar (no abdominal segments are formed) and that addition of the different parts of the BX-C one by one can restore each segment in a defined order. Lewis argued that his results demand that the BX-C contains a minimum of eight genes that 'code for substances controlling levels of thoracic and abdominal development'. A most remarkable point noted by Lewis was that the order of these genes in the BX-C was collinear with the structures along the antero-posterior axis of the fly controlled by them. Lewis also argued that each subsequent posterior segment of the body recruits the services of an additional genetic element in the BX-C linear array. Subsequent studies (see ref. 4) at molecular and genetic levels, however, revealed that Lewis misinterpreted the *cis*-acting regulatory elements in the BX-C for structural protein-coding genes: the BX-C actually has only three structural genes but multiple *cis*-acting regulatory elements which are recruited in a serial fashion to activate one or more of the structural genes of the BX-C, each of which can produce more than one kind of message due to alternative processings of the primary transcripts. However this misinterpretation does not in any way undermine the far-reaching implications of his conclusions that the BX-C genes specified the developmental pathways to build the characteristic pattern of the different body parts and that these genes worked locally. The BX-C and other homeotic genes (like the Antennapaedia-complex or ANTP-C) are also called as the selector genes which take over from the segment-polarity genes and select the specific structures that each compartment has to elaborate as the embryo continues its development[4].

While working with BX-C, Lewis did face intellectual opposition from contemporaries since the genetic organization of BX-C defied the then held beliefs about a 'gene': some mutations mapping to this locus suggested that the whole system of the *bithorax* genes was integrated while others pointed to existence of separate and separable elements of function. Unmindful of criticisms and scorn of some contemporary molecular biologists, Lewis pursued the task of understanding the system of bithorax genes which resulted in his great 1978 paper. An interesting point mentioned by Peter Lawrence in his introduction to the historic 1978 *Nature* paper by Lewis in a collection of 'Outstanding Papers in Biology'[5], regarding the publication of this paper is worth noting. To quote Lawrence[5], 'A publication from Ed Lewis is an unusual and special event. In the past 40 years his papers have been few, and their originality and idiosyncrasy has found them natural homes in unrefereed conference reports. In 1978, I had a "phone call from him to ask for help in submitting a new paper to *Nature* – an article which would consist of a 'review' of a vast amount of Lewis' own unpublished work". Peter Lawrence urged the *Nature* to 'snaffle' the paper without question and to publish it unrevised, lest the quibbles over details may cause the paper to be sent elsewhere or even delay it for a decade! As Lawrence further notes 'it is just the kind of contribution that the modern system of reviewing, with its rigid conventions and predilections against imaginative speculation, would censor. We should all be glad that *Nature* decided to publish it.'

How did these papers dealing with 'pure' genetics stimulate such a global interest? In 1978, when Lewis had published his paper, few could appreciate the import of his speculative conclusions (e. g. William McGinnis, one of the discoverers of the 'homeobox' (see later), notes[6] that the Lewis paper 'is oft cited but rarely read in its complex entirety'). Fortunately for Nüsslein-Volhard and Wieschaus, the scientific community in the early eighties had become receptive to prospects of genes controlling development and also this community was now ready to look at the genes from the molecular point of view. Combining the powers of 'formal' genetics with recombinant DNA technology, it was soon possible to clone some of these 'developmental' or 'segmentation' genes and to ask more directly how did they function. Consequently, it was possible to understand the biochemical bases for the observed effects of the various segmentation gene mutations characterized by Nüsslein-Volhard and Wieschaus and to verify the inferences drawn by them from their mutational analysis.

The most impact-making discovery that followed from these papers in the early eighties was the finding of a short stretch of highly conserved DNA sequence in the coding regions of a number of homeotic and segmentation genes. This sequence, aptly termed the 'homeobox' (denoting its association with the homeotic genes), provided a plausible biochemical function for the action of the homeotic genes whose products now appeared to be DNA-binding transcriptional regulators. Discovery of the 'homeobox' was a prelude to a flood concerning homeobox genes and homeodomain proteins, a flood that has channelled into a steady river of homeo-publications, fed by many tributaries[6]. Quickly, the homeobox was making its appearance in genes from as diverse organisms as man, mouse, chick, frog, sea urchin, nematodes and even plants (see ref. 6). Its high degree of conservation provided a simple handle to clone the developmental genes from a large variety of organisms and for many a biologist (as well as the common man since this topic had become the subject of newspaper and magazines in the eighties), the homeobox was (somewhat mistakenly!) equivalent of the Rosetta stone, the universal genetic key to body plan. The most remarkable fact that emerged from these studies was that the organization of the homeotic genes like the BX-C and ANTP-C in *Drosophila* and their counterparts in other organisms (including man) was identical.

These studies thus led to the emergence of the fundamental concept that in all organisms, the events of differentiation and pattern formation result from cascades of activity of specific groups of homologous genes which sequentially 'tell' the cells of their spatial and temporal co-ordinates and accordingly each cell gets committed to a particular path of development. Most of these genes produce transcription factors that regulate the expression of other genes. These studies showed that, as in any language a limited set of alphabets are used to create an endless variety of words and expressions by varying their combinations, in the biological system also, a limited number of regulatory genes can be used to generate a large array of patterns by expressing in different combinations in dif-

ferent cells along the antero-posterior and dorso-ventral axes.

Ever since Thomas Hunt Morgan introduced the fruit fly or *Drosophila* to genetics early in this century, this small insect has been central to the growth of the subject of genetics and thereby to many fundamental concepts in biology. It is interesting to note that Morgan himself was an embryologist who turned to genetics with a view to understanding the central issues of development and differentiation. Although by 1913 Morgan gave up 'efforts to deal simultaneously with genetics as transmission and genetics as development'[7], it is interesting to note that Morgan's objective of understanding development in terms of genetics has finally been achieved and the power of this approach been duly recognized by this year's Nobel prize in Medicine.

CORRESPONDENCE

If education is important, so must be the teachers!

I applaud the Indian Academy of Sciences' effort of exercising themselves on an important aspect of education in our country. In fact it is basically the stony silence of the 'intelligentsia' of our country that has left most of the matters that concern our lives in the hands of politicians, bureaucrats and judiciary. The result is there for all of us to see. The Academy's effort is thus very welcome.

I believe, however, there is need to look at another essential, complementary question, *i.e.* what sort of facilities should be provided to the teaching profession so that teachers become effective instruments in translating good ideas into reality.

Two major causes of the progressive deteoriation of education in universities in our country are:

(i) teaching has never been given a place of pride in hierarchy of jobs in terms of salary and service benefits,

(ii) there is rampant corruption in educational institutions in matters of selection and promotion of teachers, organization of research, etc.

The following suggestions are worth considering:

(1) An Indian Educational Service (IES) for college and university teachers and equivalent state-level educational cadres for school teachers be created, making it the BEST public sector job in terms of salary and service benefits. The necessity of making such jobs the best in the country can hardly be overemphasized if the nation really feels that imparting education and science education in particular is of utmost importance for its growth—more important than handling bureaucratic and law-and-order problems.

2. The pay-scales of teachers at all levels be time scales whereas promotion to higher cadres be made on periodic evaluation of their work by the peers drawn from as distant quarters as possible. Simultaneously, new posts be created for fusing young talented people from outside. This is, in fact, the procedure followed in research institutes and to some extent in colleges but not in the Universities! The present practice of putting people into available posts in the Universities has led to immense intra- and inter-departmental anomalies and only encourages servitude, favouritism and corruption at the cost of sound work-culture.

A minimum set of criteria, generally agreed upon, be insisted as requisite for promotion to various cadres. This should also include the students' evaluation of the teachers to be sent directly and confidentially to the evaluating authorities, say Vice-Chancellors in case of the Universities and inspectors in case of schools.

The whole point is that a teacher should be assured of his growth in the cadre only through his positive contributions to the system like teaching, research, commitment towards social issues, taking care of the overall growth of student life in the institutions, etc.

We should all accept that despite the likes of Raman, Ramanujam, Bose, Saha and Bhabha or various science institutions of repute, science has not really become a part of our culture. Our culture still continues to be dominantly feudal and colonial, denying all that science in spirit and form stands for. Resurrection is only possible through a sound educational system and that in turn requires a competent class of teachers at all levels taking pride in their profession. This requires a system that we lack so far. This is where Governments and intellectuals can come in to help erect it. Good players in good playing conditions will, by definition, make a good game. Can we ensure it ?

COMMENTARY

India's scientific community: A cultural crisis?

A. N. Mitra

Over the last 15 years, the state of science in the country has been under increasing scrutiny at major academic fora – the Indian National Science Academy[1], Indian Academy of Sciences[2], the Indian Science Congress sessions[3], periodic DST status reports[4] and Seminars in the Society for Scientific Values[5]. The theme has almost invariably been the same: There is little qualitative impact of Indian Science on the international field despite proliferation in the number of papers published in various journals. This, in turn, is a direct reflection on the state of 'University education in science' in the country. The preamble for such discussions has always been predictable: What has gone wrong since Independence in a country which can rightly boast of the pioneering achievements of Bose, Raman and Saha, all done indigenously in this very atmosphere? And let there be no mistaking the extreme poverty and the consequent non-existence of the so-called 'facilities for scientific research' prevailing in those times, and which the modern generation of academics and professional workers never tires of complaining about. Indeed, the great achievements of these giants in the pre-independence days, sitting in this very soil, as distinct from the equally impressive successes of their 'provasi' counterparts (Bhabha, Chandrasekhar), would even tempt one to wonder if there is any other 'mystery' apart from 'funds' which lies at the root of 'success' in a scientific endeavour. Ramanujan was of course a 'class' by himself, and cannot be understood in 'rational' terms. One must, of course, hasten to make a prior allowance for a fortuitous circumstance which existed 70 years ago, *viz.*, the state of flux that science, especially physics, was undergoing in those days when it was perhaps easier for a single individual to make a decisive impact on the international map than it is today. Yet a closer scrutiny of the 'nature' and 'thrust' of their investigations strongly suggests the influence of an 'indigenous' culture that is quite independent of its western counterpart, despite the general background of Western Science, in which these investigations had been carried out. This is especially true of Bose's great discovery which one may venture to guess would not have been easy to make in the then prevailing atmosphere of Western Science which had not (and still has not) recovered from the strongly 'deterministic philosophy' of the nineteenth century, and was very much 'ill at ease' with the new paradigm that had been thrust on it by half a dozen western minds in quick succession (Planck, Einstein[2], Rutherford, Bohr and de Broglie). (In this connection I am reminded of a remark by Abdus Salam in 1970 (ref. 6), in the context of a discussion on 'symmetries', namely, it is often easier and more natural for an easterner to appreciate the significance of concepts based on apparently 'conflicting' ideas such as particle–wave duality than his western counterpart, and indeed went on to cite Bose's great discovery of the very concept of indistinguishability as an example).

Apparently there are vital ingredients (other than funds and facilities) in the indigenous cultures and traditions of a given community that go to make up its scientific ethos and values.

Pre-independence scenario

Now to come back to the question which has been bothering our academics[1–5], it is necessary that one must not fight shy of looking back to the pre-independence scenario for comparison. As long as the country was under the foreign yoke, the political atmosphere was such as to keep the academics and intellectuals confined to the portals of the modest university system for all it was worth. The foreign government was simply not interested in making use of our scientific talent for genuine developmental purposes (except perhaps for occasionally hiring some scientists for help in their war efforts). Nor were the members of the scientific community anxious on their own in offering their services to the then government against the emotional tide of the freedom movement. The safest abodes for their intellectual pursuits under the circumstances were thus necessarily the educational institutions which also 'housed' the sciences in a modest way in the absence of alternative, exclusive, abodes of scientific pursuits (with rare exceptions like the Indian Association for the Cultivation of Science, the Bose Institute in Calcutta and the Indian Institute of Science in Bangalore). The result: whatever little (?) output came out of this system was truly indigenous and this included the signal contributions of the giants noted above.

The 'culture' of these educational institutions in the pre-independence days was also quite different from what it is today. The 'ambitions' of the teachers were confined to their modest academic pursuits which included offering their best attention to their students, as if they were their own children, and not from any sinecure motives. (I have seen my late father (Jatindranath Mitra) spending hours together with his students at home, over and above the limited hours spent with them at his Ramjas College, with the sole incentive if any being one of 'competition' with sister institutions for his students' performance at the University examinations, as if their successes were his own! Any other motive, especially the 'tuition' motive which is so prevalent today, was simply unthinkable then). No wonder, the students got their academic dues without ever asking for them, but more importantly, this kind of gurukul atmosphere had a profoundly salutary effect on their moral fabric which they were to propagate later to their progeny. The seminal researches of Bose–Raman–Saha were already ample evidence of the modest but indigenous research atmosphere present in the then University educational system pioneered by great visonaries like Asutosh Mukherjee (Calcutta), Madan Mohan Malviya (Banaras) and the Maharaja of Mysore, all of whom took great personal interest in bringing together

bright young workers and encouraging them in their efforts.

Post-independence: Decline of university system

This 'garden atmosphere' was however too Utopian to survive the economic challenges of the post-war era which also happened to coincide with the post-Independence era. With the dawn of Independence, our founding fathers rightly stressed the need for rapid industrial development, seeking to compress as it were the two centuries of Industrial Revolution in the West to at most a few decades. This new emphasis called for fresh priorities with its inevitable impact on the society. In this review, we are however concerned with only some aspects of this impact on a small but vital section of the society which is supposed to nurture science through a sound educational system. In the new dispensation of the then government, the universities found themselves suddenly reduced to the status of 'second class' institutions, as if to contradict the very noble sentiments of no less an authority than Jawaharlal Nehru on the true role of a university in a free society as the symbol 'for compassion, for reason, for the adventure of ideas and generally for the onward march of the nation towards still higher objectives[7]'. Not that there was any deliberate attempt to downgrade the universities, but in the then nascent atmosphere, their social status registered a sharp decline in the face of a new 'cultural revolution' caused by the creation of a chain of government-sponsored organizations such as the CSIR, ICAR, ICMR, AEC and the various national laboratories under their respective jurisdictions on the pattern of their British counterparts. The external symptom of this development was a sudden imbalance caused by the outflow of talent towards these new pastures at the immediate cost to the educational institutions which had hitherto been their traditional abodes, as well as fountainheads for the supply of intellectual and scientific talent in any country, but the negative effect penetrated much deeper (see below).

Now the growth of government-sponsored scientific organizations is inevitable in any developing society and their creation on the British pattern cannot be faulted on intrinsic grounds. Indeed in the post-war era, a similar development was also noticeable in the French System under the CNRS and like organizations[8]. However, unlike in Britain or France where the firm tradition of liberal intellectual values has always ensured a steady supply of a sizeable fraction of the intellectual cream of the society within their university systems without fear of any major depletion of talent, a phenomenon of this nature proved much too harsh for the delicate educational structure of this country in the nascent atmosphere prevailing in the post-independence period. And to make things worse, there was no evidence of a corresponding degree of concern in this country for countering the impact of this new culture through suitable checks and balances. Instead there was just a one-way development: The discovery of new form of 'glamour' in these prestigious institutions in the Indian context tended to attract the scientific manpower to the new environment by way of better economic and social prospects, while on the psychological plane, it had a negative effect which should have been anticipated: A 'devaluation' of the University system through the implied perception of a sort of 'poor cousin' status for the latter in the eyes of the society at large. Unfortunately the government made no effort to introduce any corrective measures against such an obvious imbalance which was to have a long-term detrimental effect on their healthy growth in the new scenario. For on the one hand the University system now found a major rival claimant for the modest state support that it had hitherto been used to, with the greater part of the available funds for development being diverted to National Institutions now manned by people identified as the 'top scientists' in the country many by whom had little actual contact with teaching at the brass tack levels. On the other hand, the visible indifference of these new 'managers of science' towards the problems of their 'poor cousins' (presumably for lack of any direct experience with the working of these institutions) generated a psychological feeling of social inferiority within the university community, to such an extent as to generate a genuine desire among its smarter members to migrate from the university system to 'new pastures', e.g., 'abroad'. Thus, far from strengthening the fabric of the educational structure, the new policy of the government seemed to be tantamount to 'allowing' the traditional educational institutions to 'decay with time, when its long-term concern should have quite the opposite, *viz.*, a continuous generation of scientific talent which only the latter could provide for a steady flow of scientific manpower for the expanding organizational activities in science and technology. Incidentally, this 'decay' has been strictly at the qualitative level, for with the passage of time there has been a steady proliferation of the number of universities in the country, almost in tandem with the increase of U. N. membership during the same period (while the FIVE permanent members of the Security Council dictate the deliberations and decisions). This fact, together with the utter frustration of the teaching community due to the lack of basic amenities for work, as well as of incentives for promotional avenues over the last three decades, has probably been the biggest single factor responsible for the parlous state that the university system finds itself today. The peculiar form of 'trade-unionism' now witnessed in the educational institutions is hardly distinguishable from what one is normally accustomed to in the industrial sector, and is a far cry from their 'cloistered atmosphere' of half a century earlier. In the public perception, the university system has now acquired the dubious distinction of a 'second-class citizen', what with the so-called 'promotional farce' (especially in the professorship category) which has merely served to erode its credentials further. In all fairness though, the question of 'which came first, the hen or the egg?' remains at best a speculation.

Degeneration of scientific manpower

The above is only one side of the story, one accruing to a vital sector of the society, the university system, to the decline of the scientific enterprise in the country. The other side of the coin, the state of the scientific community which forms the bulk of the scientific manpower of the government-run institu-

tion, is no more rosy, if one has to go by the frequent concerns expressed by various Academic bodies[1–5], case studies by professional experts[9], as well as numerous expressions of public concern reported in various magazines and newspapers in recent times under titles like 'tragic gap' [ed. Indian Express 3.2.95], 'plight of scientists' [Times of India, 11.3.95], to mention a few samples. (This is hardly surprising, since after all, the 'timber' of scientific manpower in the country comes from the same stock as can be supplied by the educational system itself, irrespective of whether the initial advantage of the former was at the cost of the latter). The laments expressed in these media columns, including some[10] from members of the general public, are mere variants of a common theme: 'a moribund state of science in the country'. The symptoms span a whole range of factors, both specific and non-specific. Some items are[10]:

(1) A lack of sensitivity (of authorities?) in identifying and encouraging scientists;

(2) Failure of senior scientists to champion the cause of their junior colleagues;

(3) Public unawareness of the research-funding policies. As a result, huge grant sanctions are often based on political clout of the scientist in an atmosphere of corruption and sychophancy at the bureaucratic level;

(4) Lack of peer support of upcoming young scientists due to the reluctance of the top rung of scientists to encourage talented and ambitious youngsters (barring some genuine cases). This stems from a sense of insecurity (born out of their own inadequacies, lack of commitment and complacency). The resulting effect is a gradual extinction of the 'flames of scientific temper'[10] in the young minds through a denial of access to facilities, and/or only short-term support to their research.

(5) Callous attitude of officials in the Alma Maters of young scientists, resulting in delay of sanctions, bills settlements, etc, so that the finance and purchase sections decide the time table.

The common refrain of most of these complaints is a pitiful lack of 'funds and facilities', together with a very unjust form of distribution which leaves this meagre resource in the hands of a small but influential group which would resist any sharing of scientific power down the line. Underlying this refrain is an implicit belief that the amount of any worthwhile research output is directly proportional to the available *funds and facilities*, as if to suggest an exclusion of all other factors! This is certainly an oversimplification but it goes to show how deeply the malaise has penetrated the psyche of the average scientific worker. The kind of research that is directly proportional to the 'fund available' is still quite substantial in this country, as a recent discussion in one of the premier Academies[1] would suggest, but how much qualitative impact it makes on the international scene, is anybody's guess, despite our claims to the possession of the fourth largest scientific manpower in the world. Apparently some other vital element/elements conducive to the growth of a healthy science are also involved.

Role of 'national ethos' in the growth of science

What is this vital element/elements? Perhaps a single phrase in which it/they can be summarized is a sense of 'national ethos' which binds a great nation together in terms of its different components, scientists included. Indeed it does not take too much scrutiny of the scientific achievements from any great country which has made a sizeable impact on international science (UK, USA, USSR, France, Germany, Italy and Japan) to convince oneself of the 'sense of belonging' of its scientists as its nationals trying to project the work of their colleagues as if it were their own. And this stance is visible quite naturally and spontaneously, without the slightest effort at any 'pretence'. Any member of our scientific community who has interacted with his/her 'foreign' counterpart will not fail to testify to this common characteristic which binds them together, transcending the international character of science. One would also discern a broad degree of 'cultural similarity' as well as a sense of national solidarity in their respective publications (as revealed by their referencing patterns, among other things). This is not to say that scientific pursuits in these countries are free from problems, but they are of other types (also present in our system) and their identifications, and solutions are at least not hampered by the 'cultural identity' problem.

Let us now compare the corresponding scenario in our country. To keep the record straight, there is no question of a sense of national identity not existing at the socio-political level (in the face of any external threat, we are all one), but are we equally sure that the same degree of 'cultural solidarity' obtains within the subsystem of the scientific community (which after all is not threatened by an external enemy)? Despite possible protestations to the contrary, the answer seems to be an emphatic 'no'. And the evidence lies not just in the relatively innocuous fact of our scientists being more comfortable with their activities when they 'go abroad' with obvious attractions on both the economic and the 'fund–cum–facility' fronts (this is merely an external symptom, not a cause), but rather in their very attitude of indifference to a sense of cultural and ethnic togetherness compared to their more successful western counterparts. This attitude is more easily noticeable in the themes and referencing patterns of their publications which evince an unmistakable tendency to 'lean' towards western thoughts even for mundane and routine ideas, and often show a tendency to ignore similar work emanating from their compatriots, in favour of corresponding references from more 'visible' western colleagues. This may well be due to a feeling of insecurity born out of a lack of confidence in indigenous research output, but it has the effect of snowballing into a peculiar 'collective culture' in which the indigenous component becomes the victim. It may be argued that since basic science is international in character and there is only one accepted theory by and large, such an attitude is unexceptionable *vis a vis* the theme of a paper. While this is a priori a very powerful argument, it is not free from limitations, for the same logic should also apply to the various other nationalities in western science. Yet one invariably notices some distinct 'nationalistic' flavours (American, Russian, Italian, Japanese, etc.) in their respective publications, despite a common pursuit of international science. The only sensible answer to this paradox lies in the simple fact that within the broad framework of 'accepted sci-

ence', there is plenty of scope for diversification of ideas designed to address limited sectors of investigation, and it is through such possibilities that one often arrives at 'new' insights on an 'old' problem. There is good reason to believe that such 'insights' have a sort of 'regional character' reflecting the 'national ethos' of the investigators concerned. And in any case it is difficult otherwise to account for the fact that most original discoveries have emanated from one or more of these *individual* countries, with their clear imprints, and very rarely on a 'multinational' basis.

To illustrate the nature of these 'insights', one invariably finds an abstract (often mathematical) flavour in Russian and French research publications, in contrast to a more practical 'applicational' orientation in their British and American counterparts. German and Italian Physics which used to be oriented towards the abstract and applicational respectively in the pre-war days, have undergone drastic changes since then, with a certain degree of intermixing of the two, probably as a result of the traumatic effects of the War on their respective social structures. The Japanese ethos, on the other hand, shows an interesting transition from the Eastern abstractness of the pre-war physics (Yukawa, Tomonaga and especially the Nagoya Group) to an applicational (bordering on engineering) orientation, especially since the War, perhaps symbolizing a *collective national effort* for 'catching up' with the western nations on the technological front; yet the key element has been unmistakably a collective nationalistic ethos.

Against this backdrop it is interesting to ask if any collective 'nationalistic ethos' is noticeable in the Indian context, even after half a century of the post-independence period. The characteristic imprint of 'Eastern Thought' was clearly visible in the pioneering researches of Bose, Raman and Saha, carried out in the 'splendid isolation' of their respective environments. It would be idle to ask if there was evidence of any 'national identity' under the shadow of a foreign ruler, but the themes of these papers were 'characteristically Indian' which did not prevent them from having a decisive bearing on the international frontiers of physics. True, it was a period of upheaval in Physics when it was getting reshaped in tune with the new realities, and when the chances of making a significant impact due to individual efforts were a maximum. However, it is interesting to ask if a 'Bose' or a 'Raman' could have made a similar discovery in the present environment of science in the country after 50 years of independence when our 'Eastern' philosophy should in all fairness have crystallized into a well-defined 'national ethos in science', as in the more 'mature' countries of the west. One major problem he would face is the enormous growth of Physics since the consolidation of Quantum field theory (though the current state of this theory is again in a state of flux !). The more serious handicap for him would be cultural: he would find himself as a 'Rip Van Winkle' with no trace of the indigenous scientific culture that he had (perhaps inadvertently) *initiated* 70 years ago, in today's 'voo-doo' atmosphere which pervades every section of the society, science included, making it virtually impossible for any well-defined indigenous culture, scientific or otherwise, to evolve. True, in the new world order some degree of intermixing of cultures of the East and the West is inevitable, yet it is fair to say that by and large, the cultural identities of the major nations have not been lost in the process.

Decline of cultural values

So, where do we stand in this new scenario? More pertinently, how did this remarkable increase of entropy in our 'science culture' come about? While part of the reason must be attributed to the worldwide phenomenon of increased mobility in the post-war period which has led to a considerable intermixing of scientific and cultural values, one suspects that there must have been other important factors without which it would have been difficult to account for such a qualitative transformation in a country of India's size and diversity which has maintained its cultural identity over centuries. One major factor that may stand some repetition in retrospect is the government's (short-sighted?) perspective for 'development in a hurry' by indiscriminately drawing on the Nation's 'intellectual reservoir' (the Universities) without a balancing concern for the long-term effect on the cultural health of the nation. This was done by declaring its dependence on the scientific community to be sure, but the actual implementation came about through a hurried 'patronage' to a few 'top scientists' (chosen arbitrarily) in a 'nascent' atmosphere where the Society's perception of a healthy balance between its scientific manpower and a sound educational base to generate it had not had time to crystallize. Now, while the choice of a 'Bhabha' to initiate the Nation's atomic energy programme would be deemed unexceptionable even after 50 years today, the arbitrary choice of many others as 'science managers' led to a visible imbalance in the educational and scientific community then at a crucial stage of evolution. Among various fallouts, a 'competitive' phenomenon was discernible, with some senior academicians leaving their natural habitats (*viz.*, the universities) for similar (lucrative?) placements with the government. From the long-term perspective of a healthy growth of the educational system in the country which is the fountainhead for the supply of sound scientific manpower on a continuing basis, such an episode, right at the dawn of independence, had a profoundly negative effect on the traditional image of an 'ideal society' normally associated with the pivotal role of the 'universities' in projecting this noble image. Indeed, in the eyes of the academic community, especially of the younger generation, this transformation which put the glamorous image of the Science Manager above the low-profile picture of the 'teacher' working in an educational institution was tantamount to a repudiation of its traditional value system, the long-term effect of which may be partly captured by the spirit of the following poem due to Robert Browning (?) on the occasion of William Wordsworth's appointment as Poet Laureate of England:

'Just for a handful of silver he left us;
Just for a riband to stick in his coat.
Got only one of which fortune bereft us;
Lost all others she lets us devote.
They who had gold to give doled him out silver;
How all our copper had gone for his service.'

In the Society's perception, such a lopsided perspective at the very dawn of

independence, without a corresponding corrective measure to ensure that no damage was caused to the long term health of the educational system, set the tone for *defining* the relative priorities for development of the universities *vis a vis* governmental organizations, and indeed repudiated in the process the lofty ideals set out by Jawaharlal Nehru himself[7] on the role of the universities in building up the mental health of the Nation. Once the relative priorities were so defined, the subsequent evolution of the university system (*vis a vis* the scientific organizations under government charge) took its natural course where 'shortage of funds' for scientific education was but a symptom of the many consequences to follow. And if the then Society accepted this 'value system' without proper scrutiny of its long-term effect on itself, (since in the ultimate analysis the health of the scientific manpower would be determined by that of its basic source–the university system), it is merely the price of a costly mistake made half a century earlier that we are paying today in more ways than one.

Perhaps the biggest casualty of this lopsided value system was its failure to develop some well-defined 'schools of thought' with a characteristic Indian flavour, for which the best breeding ground is the university system itself. Of course, there had been attempts to develop such schools on a localized scale, but these pockets did not live long enough to grow into an all-embracing 'Indian ethos' of the type discernible in the more successful western societies noted above. With the 'individualistic ethos' that have characterized our scientific community (in company with the rest of our countrymen, as Gandhiji had recognized well enough to advocate basically small scale industries!), the more 'influential' among them merely took advantage of this lop-sided value system to promote their individual career interests through lobbying with the appropriate authorities in a well-defined hierarchy (Science managers for the middle level scientists; the political authorities for the top rung). Apparently, the sole criterion of scientific 'visibility' lay in some sort of State recognition (in the form of national awards, higher placements, etc). Others with more conservative forms of ambition for visibility in science often chose to look for more suitable opportunities abroad. And all this transition occurred before the scientific community in the country had reached a critical size, not just in numbers but in quality, which is a standard bulwark against any major scientific injustice or aberration in any 'mature' nation. No wonder, the degeneration into such an 'opportunistic atmosphere' was not conductive to the evolution of a holistic scientific culture, and the same got progressively reflected in more ways than one. A major signature has been the publication pattern of our scientists which have shown a strong tendency to routinely follow western ideas howsoever trivial, even in mundane theoretical investigations, while in the experimental areas of applied science the themes have often no relevance to the needs of their local environments. In either field there is little sign of effort to develop an indigenous culture as is normally understood in a western science community. Instead one witnesses a hybrid 'value system' in which a desperate *cultural* dependence on 'Western' science for research ideas has come to be matched by an equally compulsive culture of sychophancy with which the members of the upper echelons of the scientific community 'look' to the 'authorities' for security of their own positions of power and influence, while those in the middle levels in turn, are only too eager to pay court to their 'superiors' for sheer survival. This typical scenario, which is reminiscent of the political culture in the country as a whole, has got perpetuated in the failure of a strong 'scientific constituency' to develop as a natural custodian of moral and scientific values in any country. Such a body which evolves gradually in a mature educational and cultural base, did not have enough time to crystallize in a healthy manner in the atmosphere prevailing in this country. We now have a 'Society for scientific values' which periodically 'assesses' the moral and cultural health of the scientific community, but it comes too late in the day (and with too little mandate to do anything but scratch the external surface of the malady) for a meaningful impact on the health of this community to day.

Strangely enough, the hazards of too much dependence on the western environment have lately started telling on the more ambitious among Indian scientists who have been experimenting with a scientific career abroad. An interesting study by an eminent scientist and his colleague living abroad[11] reveals that after the first two stages (pre- and post-doctoral) in US universities and scientific institutions which the young Indian worker finds extermely satisfying for his knowledge, and rewarding for his career, there begins a long period of professional frustration for the more ambitious among them who have an urge to compete for professional recognition with their western counterparts. No wonder many of these NRIs, including scientists, are now anxious to come back to play an active role in the Indian scenario (including the setting up of an 'ideal' science university ?), perhaps after tasting the limits of 'intellectual satisfaction' available from the West, *vis a vis* their personal ambitions. It is precisely in such situations that the true significance of a characteristic (national) ethos, something that is naturally present in the western system but has somehow got short-circuited within the Indian scenario in the process of 'evolution in a hurry', comes out in bold relief.

To keep the perspective right, it will be a gross oversimplification to claim that Indian Science has scored no visibility at all since independence, for the Nobel recognition of Subramanian Chandrasekhar a few years ago stands out loud and clear, despite the technicality of the citizenship anomaly. Among other pioneering achievements in recent times which have helped put India on the world map are those of G. N. Ramachandran (Triple helix), S. Chandrasekhar (Liquid crystals), A. S. Paintal (Science of breathlessness) and C. N. R. Rao (Surface chemistry) to name a few. Again, in the area of the theoretical sciences (mainly physical) there are a few institutions of science, mostly outside the university system, where good quality work has attracted 'proper recognition' in the international scientific community, in the sense of a "Conformity with 'normal standards' prevailing today in the international field", but nothing more concrete can be claimed in this regard. These are indices of better 'funding and facilities' in improving the quality of work in a standard institution whose

'cultural base' continues to 'look west' for fresh ideas. However, considering the vast potential of the scientific manpower in the country, a growth of much bigger dimensions would have been expected. This brings back the bigger question of the possibility of cultivating a more indigenous scientific culture (for which the intellectual 'software' can come only from our own educational system) and which alone can hold out the prospects of generating 'fresh ideas' indigenously without the compulsion of 'looking west'.

Indigenous scientific 'hardware': AEC and ISRO

For a comparison of this scenario on 'cultural software', with the corresponding scenario on the technological front, it is useful to keep on record that at least one area in which a centralized command (under an ideal leader – Homi Bhabha) has paid off quite handsomely is a successful development of an indigenous culture in the atomic energy research programme which has grown from strength to strength over the decades since independence and has now developed a strong infrastructure which is not only largely self-contained but has been continuously expanding its activities in several dimensions to generate appropriate spin-offs without external support. The international stature of this organization today owes much to the single-minded devotion of Bhabha's able followers like Raja Ramanna and his colleagues who have put this country on a firm footing on the world map. In parallel with the AEC, the sister Organization of ISRO which has also indigenously developed an equally viable infrastructure to put this country on the world map on the space front, owes much to the original vision of Vikram Sarabhai and the sustained and dedicated efforts of Satish Dhawan and his able colleagues.

The AEC and ISRO are examples of what may be called typically 'Indian ethos' developed through truly indigenous efforts. Their infrastructures are sound examples of technological self-reliance which by their very nature could not have materialized without a highly organized structure, which in turn was possible only under a unitary command with direct government control, in company with corresponding structures in developed countries.

State of scientific 'software'

Vital as these organizations are for the health and security of the nation, they are nevertheless a modest fraction of the nation's scientific and technological 'agenda' which span a whole gamut of basic and applied sciences. It is also possible to argue that any worthwhile research efforts in today's state of the art in applied sciences requires a considerable degree of *organized* effort and planning. Moreover, since the infrastructural facilities for such activities cannot be duplicated at will (because of the high cost of installation) their use must also be centralized as far as possible, which explains the emergence of specialized centres like the NSC (with facilities like pelletrons). Similarly, major experimental laboratories for specialized researches in well-defined areas (such as the GMRT) are all 'hard science' activities which necessarily require a high degree of organized and dedicated effort.

The main concern in this review, on the other hand, is not so much an indigenous infrastructure of scientific 'hardware' (AEC, ISRO, etc), crucial as it is for the Nation, as is the development of an indigenous software in the basic sciences for which the traditional breeding ground has been the university system in any country, developed or developing. It is here that one does *not* need any high degree of organization which may well be counterproductive! On the other hand, its relatively informal atmosphere provides the best soil for a gradual and spontaneous evolution of a healthy scientific culture which can be truly claimed as our own. Unfortunately in this field, our performance has been dismal for, not to speak of generating an 'indigenous' flavour, as in most successful nations, it has not even produced a well-defined 'composite' flavour after fifty years of independence, and the blame for this must be laid at the door of our educational policy which simply failed to take off, and whose worst victims have been the university system. This in turn has affected all sectors of the scientific and industrial base, in both basic and applied sciences, as a result of the 'poor software' produced at source! There is no dearth of quantity – about 4000 PhDs per annum – but this itself is more of a liability than an asset, in the absence of a 'sense of direction'. As found in a recent survey[9], this community is beset with a sense of frustration due to loss of self-esteem, lack of intellectual stimulation due to erosion of knowledge base, and a general sense of inadequacy with the environment. All these (and more) are the bane of the typical average scientist of today who has been variously depicted as a 'holy cow' and a 'fall guy' with a poor image of himself, whose labour is unrecognized and his achievements ignored. An analogous picture is also discernable in the general public's perception[10].

As against this plight of the average scientific worker, the scientific culture of the higher echelons among them presents a different kind of scenario, as succinctly described by P. K. Das, Editor, *Society for Scientific Values*, in some recent issues of its bimonthly newsletter[12,13]. In a candid though satirical exposition, the distinguished meteorologist[12] expresses the view that Indian Science is badly afflicted with the so-called 'publicity disease' among its senior and 'high profile' practitioners. In his view, this disease has considerably eroded the real scientific base of the country by sending the wrong signals to the upcoming scientists. Without going into specific examples (several of which are of recent origin), it is perhaps fair to comment that there is nothing intrinsically wrong in wanting quick publicity – this phenomenon is quite universal the world over, provided the claim for priority is endorsed by the scientific community of the worker through a journal publication and/or exposure through a conference presentation. Indeed it is precisely in such situations that the advantages of a 'national ethos' become quite crucial since the projection of such results before the wider world becomes the primary responsibility and initiative of our own scientific community itself. However, if the work is of a secondary nature, which is more often the case, he must accept the initial disadvantage of 'missing the primary bus' and forgo any claims to instant glamour/kudos before doing a more substantial (yet secondary)

investigation, which usually is a time-consuming process with little chance of instant success. Indeed it is up to the senior members of the scientific community to ensure such conformity to the accepted norms of a mature scientific society so as not to send the wrong signals to the younger members of the community as to the correct scientific perspective.

P. K. Das's second article[13] discusses the 'glamour'-oriented high profile behaviour of the higher echelons of our scientific community at the taxpayer's expense, such as (i) travelling from airport to airport to inaugurate symposia in five-star hotels (with speeches written by someone else); (ii) running down the work of others in their regional networks: (iii) and even indulging in subtle forms of plagiarism. An intriguing form of the last type shows up as 'an unduly servile attitude towards scientists from countries other than one's own'–quote from ref. 13. On the other hand, from the higher ups one often hears the oft repeated phrases like 'Scientific temper' and 'Excellence in science', as if to bring out rather tellingly a sort of inverse relationship between preaching and practising, much like two canonically conjugate (complementary?) variables in physics! One hardly hears of such phrases in the western societies where the 'scientific temper' is a routine matter for practice, not for publicity. Why is it the other way round in this country of ours? Otherwise it is again difficult to understand why a 'John Maddox' has to be periodically imported into this country every ten years (roughly coinciding with the Golden and Diamond Jubilees of our premier Academies) just to give a pat on the back of our 'scientists', or a 'certificate of merit' through the columns of *Nature*. In no other country with a mature tradition of science would such self-appointed angels be allowed to exercise such uncalled-for patronage. On the other hand, it is surprising how much can still be done in this very country by purely Indian efforts, if only the right kind of encouragement were provided.

Summary and outlook

This somewhat repetitive analysis was designed for a panoramic view as to the nature of the disease which the scientific community suffers from today, one that is intimately linked with (i) the educational system which simply failed to inculcate the proper sense of values in the initial stages of development, and (ii) with the work culture of the scientific and technological institutions at the later stages of development of the scientific worker. On both fronts he finds himself completely lost in today's scientific labyrinth which seems to be going in tandem with the political atmosphere in the country. The scientific community is merely a part of our bigger society which has been witnessing a steady deterioration of our basic value system – a sort of 'systems failure' from which no part of the society can remain immune. The only difference is that greater maturity and self-restraint would have been expected of the upper echelons of the scientific community which after all represents the 'cream' of the society. One hopes that all is not lost yet, for there are definite indications of renaissance in the major disciplines of science through the coming up of a new generation of workers with the right credentials, with good prospects of their numbers exceeding the critical size, so as to serve as the Conscience of the Scientific community of the future, as well as a watchdog against the kind of aberrations that have been witnessed during the 'transition decades' since Independence.

Ethephon enhances karaya gum yield and wound healing response: A preliminary report

Gum karaya (also known as gum kadaya) is the whitish dry exudate from *Sterculia urens* (Sterculiaceae). It is one of the least soluble gums used for many industries such as petroleum and gas, textile, paper and pulp, leather and allied products, ammunition and explosives, electrical appliances, adhesives, confectionery, medicine, pharamaceuticals and cosmetics[1]. Karaya is also known by the name Indian tragacanth as it resembles gum tragacanth produced by *Astragalus* sp[2]. There is high demand for export of gum karaya from India. Yield of this gum has shown a phenomenal decrease from 6838 MT in 1975–76 to 461.3 MT in 1990–91. During this period the price has shot up from Rs. 7491 per MT to Rs. 83, 361 (ref. 1).

The tree has a thick bark (2–3.5 cm) which appears whitish-pink on the outside. Lysigenously formed gum ducts are present in the pith and cortex of the young stem[3], but they are absent in the secondary phloem and wood. However, ducts are formed in the bark and wood in mature trees as a result of injury[4].

Commercial tapping of karaya is done by blazing, peeling or by making deep cuts in the base of the bole with an axe. These methods are wasteful and injurious to the trees, often leading to their death. On account of crude tapping methods, and over-exploitation, the population of karaya trees has markedly declined. In the absence of cultivation of the trees in regular plantations, there is grave concern about the loss of wild germplasm of *S. urens*. Presently, the Governments of Madhya Pradesh, Rajasthan and Uttar Pradesh have imposed a ban on tapping and collection of the gum karaya to allow recovery and regeneration of the trees.

As gum karaya is vital for tribal economy and as its trade value is substantial, there is a pressing need to develop a scientific and sustainable tapping method to increase the yield and to ensure the survival of the tapped trees. Here we present a simple and safe technique for tapping, with a substantial increase in the yield.

Seven trees of various sizes and ages growing in a forest near Ghatti Village along National Highway No.3 in MP (about 25 km from Gwalior), India, were selected for experimentation. Using a hand drill, 10 holes each of 5 mm diameter and 2–3.5 cm depth (based on the thickness of the bark) were bored on each tree around the stem at equal distance, about 1 m above the ground level. The holes were angled towards the base of the tree to prevent backflow of the introduced solutions. Five consecutive holes were treated with ethephon (2-chloroethyl phosphonic acid) and the other five (opposite to the treated holes) were maintained as distilled water controls. One ml of ethephon solution (containing 190/285/390 mg of the active compound per ml) or 1 ml of distilled water was dispensed into each hole.

Table 1. Yield of gum karaya from control and ethephon-treated trees

Distilled water control	Ethephon-treated	
Total amount of gum collected per tree (g)	Amount of ethephon applied (mg)	Total amount of gum collected per tree (g)
a	390	386.00
12.50	390	185.00
9.05	190	433.00
a	190	48.00
8.75	285	65.00
a	285	211.00
15.00	285	259.00
11.30 mean		226.71 mean

a. Gum was not noticed; probably the lump had fallen off before collection.

Gum produced in the control and treated holes was collected after 30 and 45 days of treatment and the data were pooled. The ethephon treatment resulted in an average increase of 20 times more gum than the control (Table 1). The total harvest from seven ethephon-treated trees tapped once was about 1.5 kg of high-quality gum. There was a marked difference in the yield among individual trees, presumably due to heterozygosity.

Notably the control holes were completely dry after 30 days, while the treated ones continued to secrete the gum. Histological examination showed that large gum ducts or cavities had been formed in the secondary phloem and wood, covering a radius of 2–3 cm around each hole in ethephon-treated trees. By 45 days, a thick wound tissue had developed at the injured regions which nearly replaced the damaged tissues.

Ethephon is conventionally used to stimulate latex flow in para rubber (*Hevea brasiliensis*), resin enhancement in pines[5], gum exudation in *Prunus*[6], *Acacia senegal*[7], *Anogiessus latifolia*[8], *Azadirachta indica*[9,10] and increase the production of kino in *Eucalyptus*[11], gum-resinosis in *Commiphora wightii*[12] and *Mangifera indica*[13]. Ethephon is a nontoxic, environment-friendly, inexpensive and easily available plant growth regulator (PGR) manufactured in India and used extensively in agriculture and horticulture[14–16]. Safe tapping and the use of ethephon for improving the yield would ensure sustainable supply of gum karaya.

We are conscious that the sample size on which our observations are based is small. Further detailed studies are being carried out using larger number of trees from separate populations in different seasons to allow statistical assessment of the efficacy of this method. A recent trial with 17 trees has shown that gum yield is high with ethephons treatment even after 10 days. Efforts are being made to standardize the protocol, optimize the yield, and determine the long-term effects on the trees. Yields need to be compared with those from the traditional tapping methods. A detailed investigation on sustained yield, cost effectiveness, extent of injury, and wound-healing response of the trees is also being carried out to verify this preliminary finding.

Occurrence of *Botryococcus* from the Lower Cretaceous rocks of Cauvery Basin, Tamil Nadu

Botryococcus, an oil-producing colonial green alga, is generally known to occur in Tertiary and Quaternary rocks of India. It is also reported from Permian sediments of India.

In course of drilling for groundwater in the area, about 1.2 km west and 1.3 km north of Kattarambakam village of Vannur taluk, South Arcot district, Tamil Nadu (Figure 1), carbonaceous shale, sandstone, coal and clay were encountered. The palynological studies of the carbonaceous shale samples revealed the presence of abundant green alga *Botryococcus*[1].

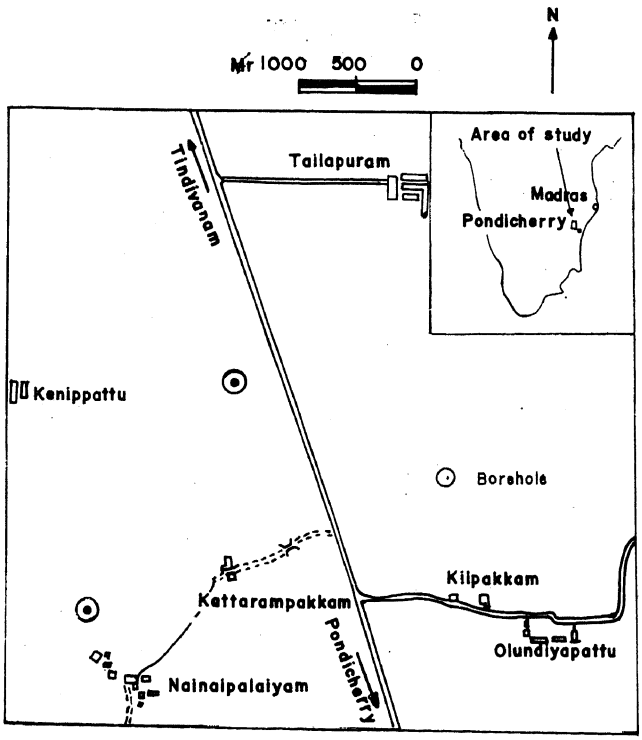

Figure 1. Location map of the study area.

Botryococcus is well preserved, honey yellow to brownish yellow in colour and occurs either as solitary autospores or bodies of two to four chambered cups (Figure 2) or as multicup aggregates. The colonies are mostly botryoidal (Figure 2) or spheroidal in shape and range from 120 to 160 μm in diameter. The diameter of the two- or four-chambered cups ranges from 16 to 28 μm (Figure 2). Further, it is also noticed that some of the colonies appear as irregular lumps of varying dimensions (Figure 2). In the present assemblage the thimble (inner part of cup) invariably remained empty.

Botryococcus is know to thrive in fresh to brackish shallow waters with undisturbed conditions in the area of relatively low rainfall[2]. The excellent state of preservation of all the developmental stages (*i.e.* autospores, two-to-four-chambered cups and multicup aggregates) is indicative of rapid burial of this algal bloom in quiet shallow oxygenated waters without much transportation[2,3].

The qualitative analysis of the associated miofloral assemblage revealed the presence of characteristic palynomorphs referable to *Aequitriradites* sp., *Microcachryidites* sp., *Dictyosporites speciosa*, *Cicatricosisporites australiensis*, *Appendicisporites tricornitatus*, *Neoraistrikia* sp., *Cooksonites* sp., *Gothanipollis*

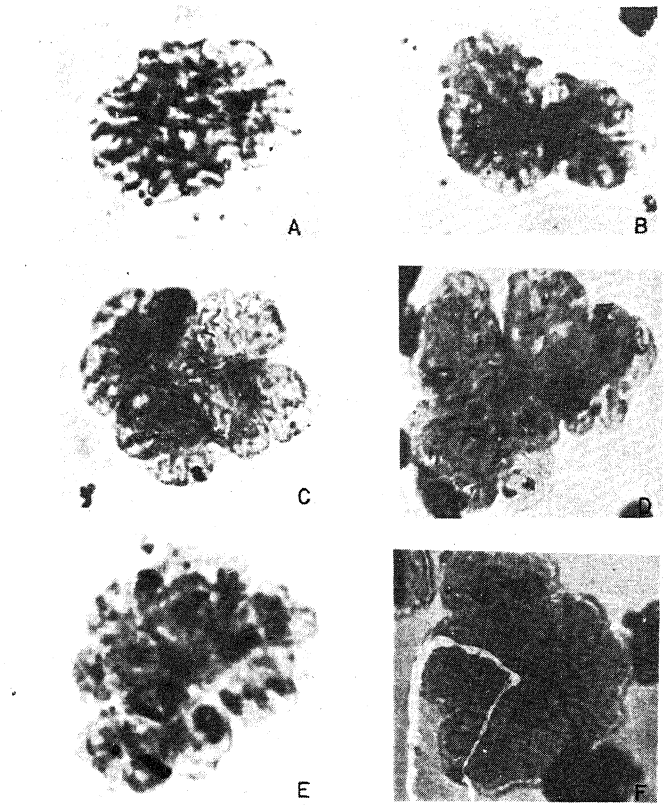

Figure 2. *Botryococcus* showing different stages of preservation: Solitary autospore (× 960); Two-chambered cup (× 960); Four-chambered cup (× 900); Botryoidal nature (× 450); Multicup aggregate (× 900); Abraded form (× 400).

sp., *Crybelosporites stylosus*, *Triporoletes reticulatus* and *T. radiates* (common occurrence) show a close resemblance with the *Triporoletes reticulatus* zone of this *Botryococcus*-bearing palynoassemblage from Kattarambakam.

Most of the fossil records of *Botryococcus* in India are from Eocene[5–7], Miocene[6–9] and Pleistocene sediments[10]. Occurrence of this alga is also reported from Permian rocks of India[11–14]. The present record of *Botryococcus* from the Lower Cretaceous (Late Albian) sediments from Kattarambakam is significant for it is the first record of this alga from Cretaceous of India.

Enechelon faults along West Coast of India and their geological significance

Subsequent to the advent of modern remote sensing technology, mapping and analysis of various lineaments and fractures and their correlation with geophysical and ground geological data have become a matter of great interest to geoscientists. The West Coast of India is one such region which has always attracted the attention of geoscientists and many have studied the region. The significant amongst them are the studies by Jacob and Narayanaswamy[1], Ramachandran[2] and Nair[3]. Jacob and Narayanaswamy[1] have observed that the Western continuity of the Palghat gap extends right up to 9° channel, separating Laccadives and Maldives. Ramachandran[2] has carried out very exhaustive analysis of lineaments by integrating total intensity aeromagnetic, Bouger gravity anomaly and Landsat lineament data sets. On the basis of such an integration, he has identified four sets of lineaments in WNW–ESE to NW–SE, NNW–SSE, N–S to NNE–SSW and NE–SW directions.

Nair[3] has carried out structural interpretation for the entire West Coast of India and brought out certain newer information on the neotectonic activities.

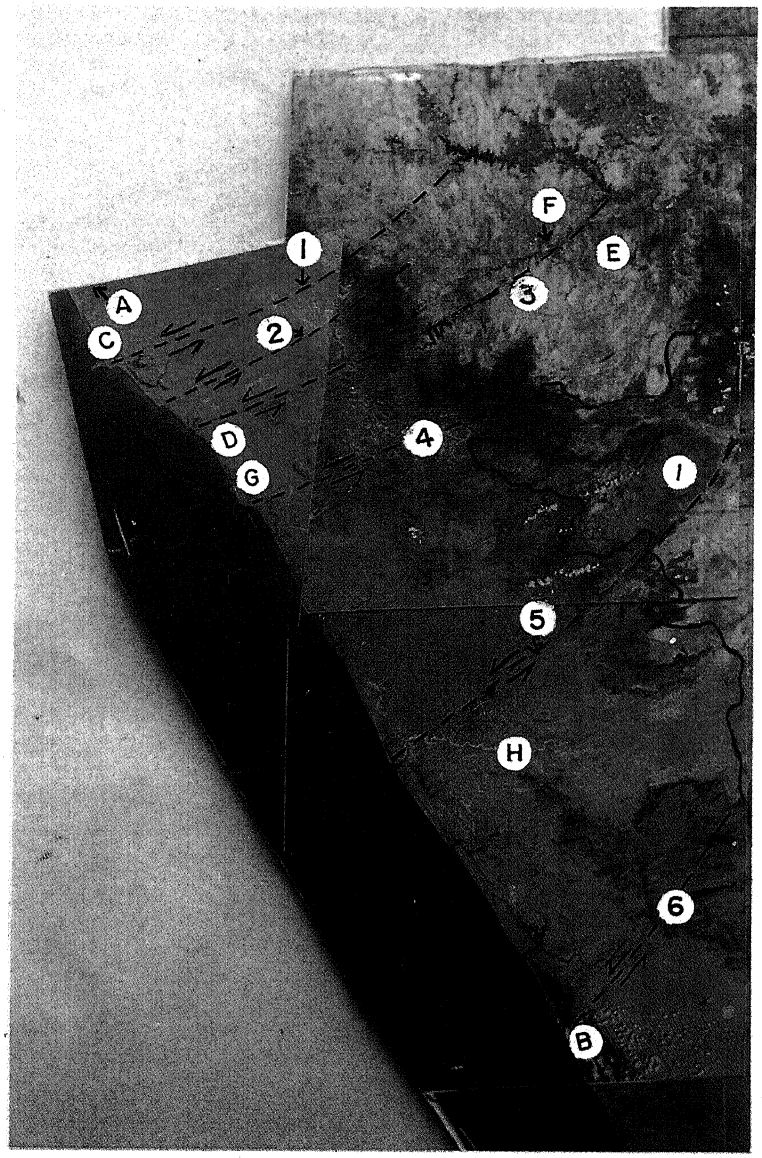

Figure 1. IRS 1A Satellite imagery mosaic of West Coast of Kerala showing Pleistocene faults. 1–6, lineaments/faults; ⊠ Sinistral faults, A, Kasargod; B, Cochin; C, Cannanore; D, Mahe; E, Mysore; F, Kabbani river; G, Pandalayini; H, Ponneni river; I, Ootacamund massif.

In the present study, I have filtered out only the lineaments showing clear shifting of beds in the coastal landforms, which mostly fall in ENE–WSW direction.

The interpretation of IRS IA satellite imagery data for the part of West Coast of Kerala and Karnataka, especially the area falling between Kasargod in the northwest and almost Cochin in the southeast (Figure 1), shows a set of ENE–WSW to NE–SW-trending subparallel lineaments, exhibiting clear sinistral shift of coastal landforms/shorelines in the area. Amongst these lineaments/faults, most of them are continuing even up to 700 to 800 km in the continent with a clear northeasterly swing. They also continue up to Laccadives and Maldives in the southwest with ENE–WSW orientation (Figure 2).

1. The fault no. 1 trends in ENE–WSW direction with clear sinistral drag of beds in the coastal zone and coincides with the Lakshmithirtham lineament of Ramachandran[2].

2. The ENE–WSW trending fault no. 2 of Cannanore region exhibits sinistral drag.

3. The fault no. 3 is again an ENE–WSW-trending linear feature, extending from Mahe in the West Coast to Mysore in Karnataka, with the swing towards northeasterly. This sinistral coastal zone fault controls Kabbani river in the continental part and is described as Kabbani lineament with dextral strikeslip configuration by Katz[4] and Drury and Holt[5].

4. The fault no. 4 shows sinistral shift of 5–6 km in the West Coast in Pandalayini area and merges with WNW–ESE trending Moyyar shear.

5. The fault no. 5 trends in general NE–SW direction from Ponnani river mouth in the West Coast to Elagiri hills in the northeast. This also exhibits minor sinistral shift of beds along Ponnani river mouth. It controls the Bhavani river and delimits the southeastern and southern boundaries of Ootacamund massif and Biligirirangan hills respectively. In its northeastern proximity, it forms the western limit of Javadi hills.

6. The fault no. 6 is trending in NE–SW direction from Cochin in the West Coast to Coimbatore in the northeast where seismicity was reported in 1900 (ref. 6).

Most of the above observed sinistral strikeslip faults are found to extend right up to Laccadives and Maldives in the Arabian sea (Figure 2) and amongst these, the fault nos 5 and 6 are found to form 9° channel, separating Laccadives and Maldives. In addition to the above faults, few more sinistral strikeslip faults were also interpreted (fault nos 8, 9 and 10, Figure 2). All these faults trend in NE–SW direction in the continental part, take a swing towards westsouthwesterly and finally ends in Laccadives and Maldives (Figure 2). Similar to fault no. 5, the fault no. 7 observed south of Alleppey continues as 8° channel in Laccadives, causing similar sinistral shifts of land in Laccadives. All the above discussed ten faults have gradually shifted not only the West Coast of Karnataka and Kerala but also Laccadives and Maldives into an enechelon pattern (Figure 2).

The above discussed six faults (nos 1 to 6, Figure 1) and the other (nos 7 to 10, Figure 2) system of faults have been demonstrated to be Precambrian dextral strikeslip faults in parts of Tamil Nadu and the adjacent states[2,4,5,7].

Such Precambrian NE–SW-trending dextral faults swing towards westsouthwesterly, with sinistral strikeslip configuration in Kerala and Karnataka coast and in Laccadives and Maldives according to the present observations (Figures 1 and 2).

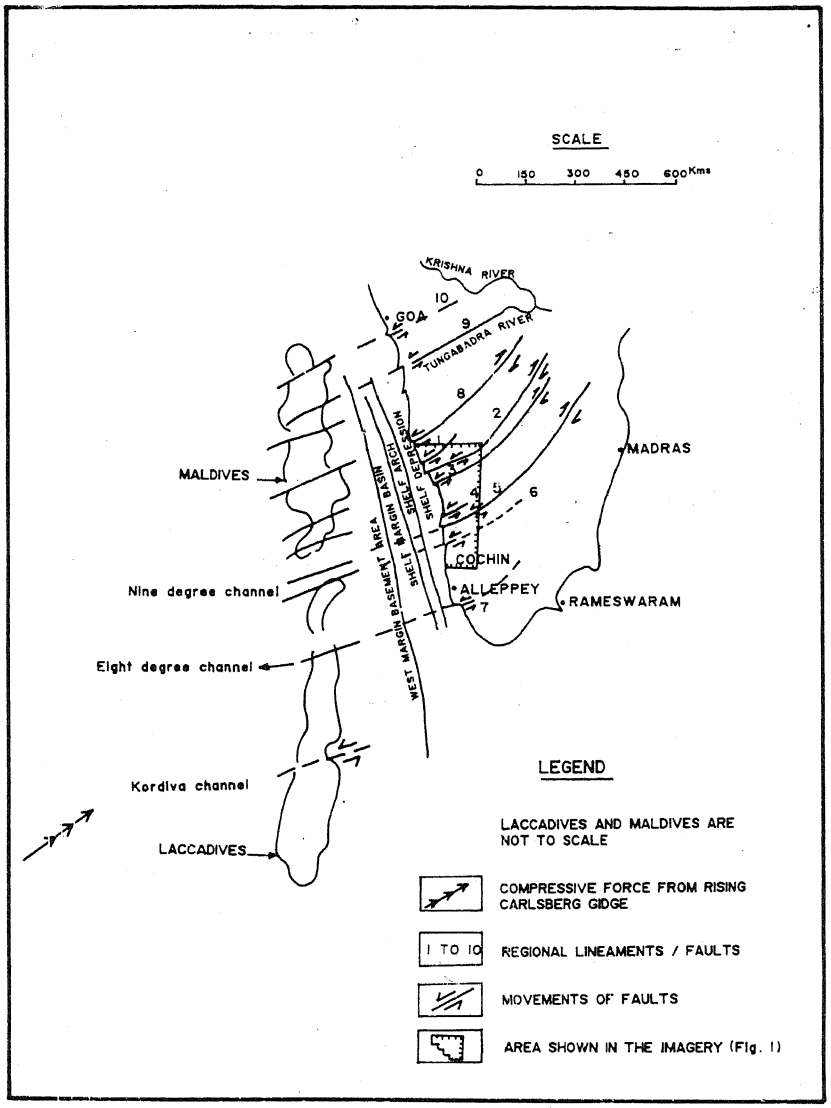

Figure 2. Off-shore and on-shore tectonic features of West Coast.

Nair[8] has also demonstrated clear Holocene earth movements along a few ENE–WSW faults in the coastal plains and also in the surf zone of Kerala coast in the form of lagoons, submerged platform, etc. He also extended few sets of ENE–WSW-trending Holocene faults right up to Laccadives and Maldives.

But, Jacob and Narayanaswamy[1] have extended the Palghat fault up to 9° channel in Laccadives and Maldives. On the contrary, the present study and also the studies by Nair[8] advocate the possibility of extending only the ENE–WSW-trending fault right up to 9° channel and similarly the other faults up to Laccadives and Maldives. Ramasamy and Balaji[7] have once again found that almost all the ENE–WSW-trending faults of Kerala and Karnataka are Pleistocene sinistral faults. Thus, it indicates that all the Precambrian NE–SW-trending regional dextral strikeslip faults of the continental part have been transformed into Pleistocene sinistral faults in the West Coast.

Ramasamy *et al.*[9] have demonstrated an E–W-trending cymatogenic arch between Mangalore in the West Coast and Madras in the East Coast. Subrahmanya[10] too found an upward along Mangalore and Madras alignment.

The integration of such an E–W-trending cymatogenic arch with present set of ENE–WSW to NE–SW-trending sinistral strikeslip faults indicates that these ENE–WSW trending sinistral faults of Kerala are referrable to Left lateral wrenches[11]. And if so, the E–W-trending Mangalore and Madras arch and the sinistral strikeslip faults might have been formed due to the northerly directed compressive force which may be related to the movement of Indian plate towards Tibetan plate.

The possibility for such northerly directed compressive force as a source to Mangalore–Madras arch has also been suggested by Ramasamy *et al.*[9].

An alternate model is also possible to explain these sinistral faults. Lepichon[12] has observed that the Carlsberg ridge is raising at the rate of 1 to 30 cm per year, thereby causing northeasterly directed force towards Indian subcontinent. Radhakrishna[13] has observed NNW–SSE-trending onshore Quaternary fractures in the West Coast of India and attributed the same to an ENE–WSW-trending post-trappean compression.

Ghosh and Zutshi[14] have identified a number of NNW–SSE-trending continental depressions, continental shelf arches and shelf margin basins (Figure 2). All these observations suggest that the West Coast region is being subjected to ENE to northeasterly directed force due to the rise of Carlsberg ridge.

This might have caused not only onshore and offshore NNW–SSE-trending arches, deeps and flexures but also would have transformed the pre-existing Precambrian dextral faults into sinistral ones. However, the morphology and the dynamics of such coastal faults need deeper studies for a better understanding of post-collision tectonics.

Interpretation of nucleotide/protein sequence data: Some pitfalls

Identification of unknown genes and their products by computer search have received high priority among molecular biologists. However, since biologists are not always computer analysts at the same time, there always exists a finite probability of making errors in analysing sequences and in interpretation of data which can easily be avoided with some advice from computer analysts. We would like to highlight some of the precautionary measures that need to be taken to avoid the inherent pitfalls in sequence data and their proper interpretations.

The worst and a very common source of errors in DNA sequences is the contamination of vector sequences arising during cloning and subcloning of DNA fragments. In 20,000 sequences in the GenBank 63 alone, more than 50 instances of cloning vector contamination have been detected[1]. In a smaller number of cases the anomalous sequences might have arisen during editing, but in a majority of the cases, large blocks of vector sequences contaminated the actual sequence. Incorporation of anomalous sequences, particularly in the coding regions, not only hinders the recognition of low-level homologies and consensus sequences, but can also exhibit false similarities with other sequences, leading to erroneous conclusions. An example of such an error is in the nucleotide sequence of the *recA* gene of *Vibrio cholerae*[2] published from our laboratory. While careful sequencing of both strands and comparison of the sequence-based restriction maps with the map of the cloned DNA fragments might eliminate the problem, vector contamination can be easily and quickly detected and removed using computer programs that are now available[1]. The contamination can also be removed by comparing the sequence with the dataset of vector sequences available at the GenBank.

'Frameshift' is another frequently occurring error in DNA sequences[3,4]. This happens when a base is either missed or added during reading of sequencing gels. Posfai and Roberts[5] have detected many such errors in EMBL (release 24) and GenBank (release 56) using the program DETECT, which examines alternative reading frames from related proteins. The program BLASTX[4,6] based on BLAST[7] algorithm can also predict frameshift errors by comparing the translated nucleotide sequences from all six reading frames with a protein database. When the similarity to a protein switches from one frame to another in the same strand of the query sequence, there is definitely a frameshift error in the sequence[4]. However, with the simultaneous translation and alignment algorithms, proteins with $>30\%$ sequence identity can be reliably recognized even in the presence of 1% frameshifting error rates and 5% base substitution rates[8].

In nucleotide sequence analysis, unknown complete or partial open reading frames (ORFs) are often encountered along with the sequence of the gene of interest[4,6]. These ORFs, overlooked in most cases by the investigators, might represent useful functions. Two computational approaches are now used either independently or in combination to determine whether the overlooked putative ORFs are indeed bonafide genes[3,4,6]. The first is an intrinsic approach, which distinguishes the coding regions from the non-coding ones on the basis of the statistical analysis of some parameters of the sequence without referral to any other sequence[4,6,9,10]. The software that has been extensively used for this purpose in human genome sequence analysis[2] is GRAIL[11], which utilizes the sensor-neural network approach to evaluate the intrinsic properties of the DNA sequence like frame bias, dinucleotide fractal occurrence, etc. This approach can also be used in the analysis of small genome after proper modification. Using the GenMark method based on phased Markov Chain model, Borodovsky *et al.* predicted expressed ORFs in the unannoted regions of *Escherichia coli* genomic DNA from EcoSeq6 database[12]. The second approach for predicting genes is extrinsic and involves comparison of the putative deduced amino-acid sequence with protein sequence databases and searching for motifs[4,6]. If the deduced amino-acid sequence of the putative ORF shows 'significant' similarity to one or more proteins in the database, it is almost certain that the putative ORF represents a bonafide gene. It may be pseudo- or cryptic gene, but is definitely not a part of non-coding region[4]. Using these two approaches, a large number of new genes in the unannoted regions of *E. coli* genome have been identified and searches for genes that have escaped detection so far in several other organisms are in progress.

To search for homology of a newly generated protein sequence with other sequences, i.e. databank one or the other alignment programs are used[7, 13–15]. If

after suitable gaping more than 25% residues of two protein sequences longer than 100 residues are identical, they must be evolutionarily and/or functionally related[16]. If the identity is between 15 and 25%, the sequences are considered to be marginally similar and in the language of computational biology, this range is known as 'twilight zone'[16]. Although this criterion of assessing 'similarity' between two sequences is acceptable, a more rigorous approach is provided by the BLAST program[7] where a probability factor (p) is assigned to each alignment, which decides whether the observed similarity between two sequences could have been obtained by chance[4]. Usually $p < 10^{-4}$ suggests genuine homology between two sequences and $10^{-4} < p < 10^{-1}$ constitutes the 'twilight zone'[4]. When the similarity between the two sequences falls in the twilight zone, some caution should be taken to decide whether the sequences are genuinely related or the twilight alignment is an artifact. Ignoring alignments with $p > 10^{-4}$ might eliminate the possibility of detecting false relatedness, but such stringent restrictions might hinder detection of weak but genuine relatedness between two sequences. What is recommended in these cases is to check whether the alignment in the twilight zone is conserved in a protein family. The software MACAW[17] can detect subtle similarities between protein sequences.

Protein sequences which have 'biased amino acid composition' often generate erroneous conclusions regarding its relatedness with other proteins with similar type of bias. For example, heat-shock proteins have clusters of charged amino-acid residues[18], the human transcription factors are rich in glutamine[19], zinc finger proteins and homeo-box regions of DNA-binding proteins have bias towards positively charged amino-acid residues[20]. If a new sequence has any of these characters, it will show similarity in the region of bias even when the proteins are functionally not related. This problem can be solved by filtering out the regions of bias before searching for similarity with other proteins. The program SEG can filter out the biased or 'low-complexity' regions from a sequence[6].

Computers function objectively and in computer searches there is no scope for prejudice that is often associated with experimental studies. This advantage of computational methods, the explosive growth in sequence databases and the availability of a wide variety of analytical software packages have, in recent years, encouraged molecular biologists to undertake computational analysis of nucleotide and protein sequences to derive a variety of information. To exploit fully the sequence data it is, however, necessary to assimilate new approaches of computational methods and this can only be realized through users having strong background not only in molecular biology but also in computers.

Fifty years of the exact solution of the two-dimensional Ising model by Onsager

Somendra M. Bhattacharjee and Avinash Khare

The exact solution of the two-dimensional Ising model by Onsager in 1944 represents one of the landmarks in theoretical physics. On the occasion of the fifty years of the exact solution, we give a historical review of this model. After briefly discussing the exact solution by Onsager, we point out some of the recent developments in this field. The exact solution by Onsager has inspired several developments in various other fields. Some of these are also briefly mentioned.

1. Introduction

It is usually said that every theoretical physicist must know (ideally must be taught) the landmarks of theoretical physics. Some of these are: g-2 calculation in quantum electrodynamics, Onsager's exact solution of the two-dimensional Ising model etc. It is our privilege to briefly discuss Onsager's exact solution of the Ising model and its influence in the subsequent developments of statistical mechanics[1]. To appreciate why it is regarded as one of the landmarks of theoretical physics, it is worth remembering that for a long time it remained the first and the only (mathematically rigorously) exactly solvable model exhibiting phase transition. Its discovery completely changed the course of development in statistical mechanics and also other areas of physics. Before Onsager's exact solution, it was not clear if the formalism of statistical mechanics could handle phase transition. The solution established beyond doubt that phase transitions appear as singularities in the thermodynamic functions and these functions need not have simple discontinuities as hypothesized by Ehrenfest before. Furthermore, of all the systems in statistical mechanics on which exact calculations have been performed, the 2-dimensional Ising model is not only the most thoroughly investigated but it also the most profound. Its significance was instantly recognized. In this context we would like to recall the letter written by Pauli to Casimir immediately after the World War II. Casimir in his letter had expressed his concern about being cut off for so long from theoretical physics of allied countries. Pauli in his reply said 'nothing much of interest has happened except for Onsager's exact solution of the two-dimensional Ising model'[2].

The plan of the article is as follows: In §2 we first define the Ising model and give an historical account of the various approximate solutions developed leading to the exact solution of Onsager[3]. We shall also briefly mention the relevance of the model. A short sketch of the life and works of Onsager is given in §3. In §4 we review the exact solution of Onsager[4] and its importance. Some of the open, unsolved problems are also mentioned here. It must be made clear here that our aim is not really to discuss the exact solution since there are several places where an excellent account has already been given. In §5 we discuss the various developments in this field which have been directly inspired or influenced by Onsager's work.

Somendra M. Bhattacharjee and Avinash Khare are at the Institute of Physics, Sachivalaya Marg, Bhubaneswar 751 005, India.

2. The model and its brief history

The Ising model was in fact first written down not by Ising but by his thesis supervisor W. Lenz[5] in 1920 who was then working in Rostalk University in Germany. It is somewhat unfortunate that the physics community has given him no credit for this work. This is perhaps because even though Lenz introduced the model, he did not do any calculations using this model. It is perhaps worth recalling that Lenz is instead well-known for his work on Runge–Lenz vector in the context of the accidental degeneracy in the hydrogen atom problem. Lenz moved to Hamburg as professor in 1921. One of his first Ph D students was Ernest Ising who was born on May 10, 1900. In late 1922, Lenz asked Ising to study his model and the phenomena of ferromagnetism. Ising studied the model and found its exact solution in one dimension and showed that there is no phase transition from para to ferromagnetism[6]. Since then the model is known as the Ising model. Let us now briefly state the Ising model.

The model

It is a lattice model. Consider a d-dimensional periodic lattice (d = 1,2,3,...) having an array of N fixed points. The lattice may be of any type. For example, one could

have 3-dimensional cubic or hexagonal lattice. However, we shall mostly considering the two-dimensional square lattice since it is for this that Onsager obtained his exact solution. With each lattice site is associated a spin variable S_i ($i = 1,2,..., N$) which is a number being +1 or −1. If it is 1 or −1 we call it spin up or spin down. Clearly, a given set of numbers $\{S_i\}$ specifies a configuration of the whole system and that there are in all 2^N different configurations. The energy of the system in a given configuration S_i is defined to be

$$E\{S_i\} = -\sum_{<ij>} J_{ij} S_i S_j - B\sum_{i=1}^{N} S_i, \qquad (1)$$

where B is the external magnetic field. Usually one assumes that the interaction is isotropic (i.e. $J_{ij} = J > 0$) and that there is only nearest-neighbour interaction. For example, for a 2-dimensional square lattice, the number of nearest neighbours is 4. Given the energy of the system, the goal is to compute the canonical partition function ($\beta = (kT)^{-1}$, where k is the Boltzmann constant and T is the temperature)

$$Q(B,T) = \sum_{S_1}\sum_{S_2}\cdots\sum_{S_N} e^{-\beta E\{S_i\}}, \qquad (2)$$

and hence the thermodynamic properties, and to see if the model exhibits and phase transition at a finite nonzero temperature. In other words, in magnetic systems, each molecule has a spin that can orient up or down relative to the direction of the applied external magnetic field B. The question one would like to ask is if this model could lead to spontaneous magnetization i.e. if below a certain critical temperature T_c, $M(B = 0, T)$ which is essentially same as the order parameter $\bar{L}(B = 0,T)$, is nonzero or not. Here the magnetization $M(B,T)$ is related to the partition function by

$$M(B,T) = +\frac{\partial}{\partial B}[\ln Q(B,T)].$$

It is worth pointing out here that the Ising model equally well represents a model for (i) binary alloys and (ii) lattice gas. Binary alloys are mixtures of two types of molecules (for example β-brass has a cubic structure made out of Zn and Cu atoms) and the question is if below a certain temperature T_c, there is a phase transition with atoms of the same type clustering together. On the other hand, in lattice gas models, one considers a mixture of molecules and holes (i.e. empty spaces) on a lattice and the question is if below T_c, there is a condensation of molecules into one region of space and holes in the rest of the lattice? Yang and Lee[7] discussed this model and gave a detailed mapping between it and the Ising model. It may be noted here that the lattice gas models are of relevance in the context of gas–liquid and liquid–solid transitions. We thus see that the study of the Ising model is of relevance in a number of phenomena. Infact for $J < 0$, this model could very well represent (I) antiferromagnetic ordering, (ii) superlattice structure in any alloy, and (iii) a solid-like arrangement of molecules with repulsive forces.

A point in order at this stage. Many people tend to dismiss the Ising model as an over-simplified representation of intermolecular forces. However the point to note is that the essential features of the cooperative phenomena (i.e. long range order), specially near T_c, do not depend on the details of the intermolecular forces but on the mechanism for propagation of long range order and Ising model offers much hope for an accurate study of this mechanism.

Historical developments

As mentioned above, Ising was able to obtain the exact solution of the model in 1-dimension[6] and show that there is no phase transition at $T \neq 0$. He then gave some arguments and erroneously concluded that even in two or three dimensions this model will not exhibit any phase transition. This dissuaded several people from working on this model and prompted Heisenberg[8] to introduce more complicated vector interaction between spins known popularly as the Heisenberg ferromagnetic interaction. It is interesting to note that Ising seriously believed in his conclusions and felt very frustrated that the model has no usefulness and gave up physics research! Being a Jew, he was prosecuted in Germany and was dismissed from his job in 1933. He managed to run away from Germany and lived in Luxemberg from 1939 to 1947. During all this time he had no contact with physics and lost track of future developments about the model. Only in 1947 when he went to USA to teach did he realize that his name has become immortal because of the work done by other people!

Almost a decade after Ising's work, Bragg and Williams[9] studied the model in the mean field approximation. They were inspired by an earlier work of Gorsky[10]. The essential assumption here is that the energy of an individual atom in any configuration is determined by the average degree of order prevailing in the entire system rather than by the fluctuating configurations of the neighbouring atoms. Clearly, this approximation is exact in the limit $d \to \infty$. One of the serious criticisms of this approximation is that it is independent of the dimension d. This approximation predicts a phase transition in the Ising model at finite T for any d which is clearly wrong for $d = 1$ as one knows from Ising's exact calculation.

Soon afterwards, Bethe[11] improved upon the Bragg–Williams approximation by treating somewhat more accurately the interaction between the nearest neighbours. It turns out that this approximation is in fact exact for 1-dimension and hence does not predict phase transition at any finite nonzero T while for 2 and higher dimensions,

it does predict spontaneous magnetization. Soon afterwards, Peierls[12] wrote a paper entitled 'On Ising's model of ferromagnetism' in which he gave a simple argument showing that at sufficiently low temperature, Ising model in 2 or 3 dimensions must exhibit spontaneous magnetization. It turned out much later that his argument involved an incorrect step[13] but nevertheless, the conclusion and the general procedure are correct. This was an important step, and the method is used even now in various situations.

The first exact quantitative result for the 2-dimensional Ising model was obtained by Kramers and Wannier (see ref. 15) when they located the transition temperature by using the symmetry of the two-dimensional lattice to relate the high- and low-T expansion of the partition function. On February 28, 1942 there was a meeting of the New York Academy of Sciences in which Wannier gave a talk on this work. At the end of his talk, Onsager made a remark announcing that he has been able to obtain the exact solution of the 2-dimensional Ising model for a square lattice and without external magnetic field. It is very significant though, that he published his results in a journal only two years later. In fact this was always his style. He could see through the math and get the final result but was careful to publish his results only after he had satisfactorily settled all the mathematical questions.

3. Onsager – His life and works

Lars Onsager was born at Oslo in 1903. Even though he got his degree in chemical engineering in 1925 he devoted most of his time to studying math and physical sciences. In 1931 he wrote two monumental papers in *Physics Review* about reciprocal relations in irreversible processes. Eventually, for this work, he received Nobel Prize in Chemistry in the year 1968. The Nobel citation noted that the publication (two papers in *Physical Review* of length 22 and 15 pages) was one of the smallest ever to be awarded a Nobel prize! In 1933 he was offered the Sterling post-doctoral fellowship at the Chemistry Department of Yale University. But there was one small problem. Onsager had never written his Ph D thesis! He was persuaded to write one which he did on the properties of Mathieu functions. This work is recognized as one of the significant contributions to the subject. In 1934 he became the faculty member of the department. From 1944 till his retirement in 1972 he occupied the J. Willard Gibbs chair of Theoretical Chemistry at Yale University. In 1972, he moved to Miami University where he worked in the Centre for Theoretical Studies till his death in 1976.

During his entire career, Onsager only published about 60 papers but each was an important one published only after he was fully satisfied with its significance and its mathematical rigour. Many a time he announced his results in conferences as a remark after some talk but published the results much later or never did! We will see one such example below. He would call himself a chemist but truly speaking he was one of the last true universalists of this century. For more information see ref. 14.

4. Onsager's exact solution of the 2-D Ising model

To appreciate Onsager's exact solution, it is worth recalling the work of Kramers and Wannier[15,16] before Onsager where they showed that the partition function for this problem can be written as the largest eigenvalue of a certain matrix. Onsager's method was similar to these authors except that he emphasized the abstract properties of rather simple operators rather than their explicit representation by unwidely matrices. It must be said here that his method is highly nontrivial and complicated. Actually his derivation can be easily followed step by step but the overall plan is quite obscure. Since a simplified version as given by Bruria Kaufman[17] has been discussed at a number of places including textbooks we shall merely quote the result. Onsager showed that the canonical partition function $Q(B=0,T)$ in the limit $N \to \infty$ is given by

$$\lim_{N\to\infty} \ln Q(B=0,T) = \ln(2\cosh(2\beta J)) + \frac{1}{2\pi}\int_0^{\pi} d\phi$$

$$\ln\frac{1}{2}\left(1+\sqrt{1-\kappa^2\sin^2\phi}\right), \qquad (4)$$

where $\kappa \equiv 2\sinh(2\beta J)/\cosh^2(2\beta J)$. From here it followed that the specific heat $C(B=0,T)$ defined by

$$C(B,T) = k\beta^2 \frac{\partial^2}{\partial\beta^2}[\ln Q(B,T)], \qquad (5)$$

diverges logarithmically at $T \to T_c$ where T_c is given by

$$\tanh\frac{2J}{kT_c} = \frac{1}{\sqrt{2}} \Rightarrow \frac{kT_c}{J} = 2.269185 \qquad (6)$$

For comparison, kT_c/J is predicted to be 4 and 2.88 in the mean field and the Bethe approximations respectively.

Over the years, several alternative simplified methods have been given but all of them are quite involved and lengthy. Bruria Kaufman[17] gave a simplified proof which is based on spinorial representation of the rotation group and it is this proof which is essentially given in K. Huang's book on statistical mechanics. Further, using Onsager's proof, the exact partition function and hence other properties of several other 2-dimensional lattices have been deduced. Finally, Onsager and Bruria Kaufman[18] calculated spin correlation functions

Further developments

To justify calling the phenomenon at $T = T_c$ a phase transition, one has to examine the long range order i.e.

spontaneous magnetization and show that it is nonzero. This is a very difficult calculation since it has to be done with $B \neq 0$ (but could be small) at the beginning of the calculation and finally putting it equal to 0 at the end of the calculation. On August 23, 1948 there was a talk by Tisza at Cornell University. At the end of the talk, Onsager walked up to the blackboard and coolly announced that he and Bruria Kaufman had solved this problem and they indeed found that the long range order is nonzero. Infact he even wrote down the formula on the blackboard. He repeated his comments at the first postwar IUPAP conference on Statistical Mechanics at Florence in 1949 after a talk by Rushbrook. However, Kaufman and Onsager never published their calculations; they only appeared as a discussion remark[19]. In print the first full calculation was in fact published by Yang[20]. Why did Onsager not publish his results? Years later, only in 1969 did he give the reason. In computing the long range order, Onsager was led to a general consideration of Toeplitz matrices but he did not know how to fill out holes in the maths – by the time he did, mathematicians were already there! What Onsager and Yang had obtained was that as T goes to T_c from below, the long range order $\overline{L}(B=0,T)$ is given by

$$\overline{L}(B=0,T) = (1-T/T_c)^{1/8} \quad (7)$$

while it is zero if T approaches T_c from above. It may be noted here that both the mean field and the Bethe approximation predict completely wrong behaviour i.e. they predict that $\overline{L}$ will go like $(1-T/T_c)^{1/2}$. These approximations do not also reproduce the logarithmic divergence of the specific heat. This difference with the approximate theory is rather important. One realizes that near T_c the nature of singularity is rather subtle. No matter what approximation one does, short of an exact solution, one never gets the log. This drives home a point that singularity is due to certain special circumstances that get killed by the approximations. It was several years later, that it could be identified as the effect of fluctuation, as reflected through fluctuation–response theorem. The universality of various phase transitions comes from the nature of fluctuations. It is the renormalization group approach developed by Kadanoff, Wilson and others, that gave the proper framework to handle fluctuations[21].

Unsolved problems

To appreciate how nontrivial Onsager's exact solution of the 2-dimensional Ising model was, let us remember that till today the exact solution of the 2-dimensional Ising model in nonzero external magnetic field has not been obtained. Further, the 3-dimensional Ising model with or without external magnetic field is also an unsolved problem. Similarly the 2-dimensional Ising model with any additional interaction (as, e.g., nearest and next-to nearest neighbour interactions) is also an unsolved problem. However special cases like the three-spin interaction on a triangular lattice can be solved[23].

5. Influence

Let us go back to the paper and discuss some of the developments where the 1944 paper played a direct role.

Duality

Duality between high temperature and low temperature for the Ising partition function was known before the Onsager Solution. However, Onsager used it to the fullest extent and introduced the idea of star-triangle (ST) transformation that could be used to solve the triangular lattice problem. The existence of duality is important because 'it always converts order into disorder and vice versa'[4]. Since the low temperature ordered phase is characterized by an order parameter, it seems possible to define an analogous quantity for the high temperature phase also. It is only in the eighties that such 'disorder' parameters played an important role in conformal invariance. The ST transformation turned out to be important in a different development when attempts were made in the 70's to solve more complex models, like vertex models. The existence of duality and ST guarantees the existence of commuting transfer matrices as expressed through the Yang–Baxter equation. The solvability of these models relies heavily on such commuting matrices[22].

Transfer matrix

The major problem was to diagonalize the transfer matrix. The largest eigenvalue determines the thermodynamic behaviour. Onsager could find all the eigenvalues for a finite lattice. This had implications far beyond the original idea of getting only the free energy.

Onsager's result showed that for a square (or any 2-dimensional) lattice, four different terms are needed if periodic boundary conditions are used. Why four was answered in a clear way by Kasteleyn in 1963 when he gave a general procedure for solving the Ising model using combinatorics ('dimers'). Kasteleyn showed that for a surface of genus g, 4^g 'terms' are needed. For open boundary conditions i.e. for strictly planar lattices, $g = 0$ while, for periodic boundary conditions, $g = 1$ as it has the geometry of a torus[23]. This also indicates that pushing the same approach to solve a 3-d lattice would require an infinite number of terms.

Correlation length and correlation

Since Onsager could find all the eigenvalues, he could also identify the correlation length. If $\lambda_1 > \lambda_2 > \lambda_3 \ldots$ are the eigenvalues, then the partition function can be written as

$$Q = \lambda_1^N \left[1 + \left(\frac{\lambda_2}{\lambda_1}\right)^N + \ldots\right], \quad (8)$$

where N is the number of rows in the direction of transfer. The phase transition occurs when the largest eigenvalue is degenerate. Close to the critical point, one can write $(\lambda_2/\lambda_1)^N \sim e^{-N/\xi}$ where $\xi = -(|\ln \lambda_2/\lambda_1|)^{-1}$. This identifies ξ as a special length scale to characterize the critical behaviour. The degeneracy of the eigenvalues as $T \to T_c$, in turn, implies a diverging length scale at the transition point. In this way, Onsager showed that $\xi \sim |T-T_c|^{-\nu}$ with $\nu = 1$. The renormalization group approach mentioned earlier is based on the idea of a diverging length scale so that the system is scale invariant at the critical point.

Later on, in 1949 Kaufman and Onsager showed that at $T = T_c$, spin correlation $\Gamma(r) \equiv < S(0)S(r) >$ decays as $r^{-1/2}$ for large distance[18]. In 1965, Patashinskii and Pokrovsky suggested the now famous scaling form $\Gamma(r,T) \approx r^{-1/4} D(r/\xi)$ where, apart from the power law prefactor, all distances are scaled by the correlation length at the temperature[24]. Explicit calculations could put the correlation function, in the proper asymptotic limit, in the scaling form but it was also noted that for $T < T_c$, $\Gamma \sim e^{-r/\xi}/r^2$. This anomalous behaviour in the low temperature phase is a very peculiar property of the Ising model in zero magnetic field. It is in the eighties that this point got clarified through the use of directed polymers[25].

Boundary effects

Onsager recognized the importance of boundary conditions. He realized that changing the couplings in one row to antiferromagnetic coupling ($J \to -J$) would increase the free energy in the ordered state because across this line spins cannot be aligned as in the bulk. This change, in other words, will force an interface in the system. The increase in free energy is then the energy of the interface or the surface tension. Since the interface vanishes at the critical point, the surface tension also vanishes at $T = T_c$. The exact solution showed that the surface tension vanishes as $(T_c - T)^{\mu}$ with $\mu = 1$. More general arguments later on proved that $\mu + \nu = 2$ for the 2-dimensional Ising model. For any other model the right hand side would involve the specific heat exponent also.

Finite size effects

Since the partition function was known for finite lattices, the specific heat could also be calculated. It was shown that, at $T = T_c$, the specific heat per spin, C, is finite. No phase transition can take place in a finite system. Furthermore, $C \sim \ln N$ as $N \to \infty$ (for a $N \to \infty$ lattice). It took many years to grasp the significance of this result until the idea of finite size scaling was introduced in 1970. Finite size scaling now plays an important role in the analysis of numerical data in a wide variety of problems.

A more dramatic result, though cannot be found explicity, in the Onsager paper, is the finite size behaviour of the free energy. Collecting various terms, from the calculation of the specific heat, it was found that for an $m \times n$ lattice

$$\lim_{m\to\infty} \frac{\ln Q_{mn}(T_c)}{mn} = \frac{2G}{\pi} + \frac{1}{2}\ln 2 + \frac{\pi}{12}\frac{1}{n} + \ldots, \quad (9)$$

where G is the Catalan constant. This is to be contrasted with eq. 8 for $T \neq T_c$ where there is an exponential approach to the large lattice (thermodynamic) limit. In 1986, Affleck argued using conformal invariance that in two dimensions, at criticality.

$$\lim_{m\to\infty} \frac{\ln Z}{mn} = \text{const} + \frac{c\pi c}{6n}$$

with c the central charge as the only quantity required to identify the critical behaviour ('universality class') in 2 dimensions[26]. A comparison of the two gives $c = 1/2$ for Ising model.

Experiment

The simplicity and wide applicability of the 2-dimensional Ising model and its solution still leave behind a queer sensation that, after all, the model is a bit artificial. So far as the exponents are concerned, they are universal and a wide variety of systems do have Ising exponents. It however remained a challenge to find an experimental system that could exhibit the behaviour one finds from a landmark of theoretical physics. The challenge was met when an alloy was found in 1974 which showed the behaviour of magnetization exactly like the Onsager result with only T_c as the adjustable parameter[27].

MEETINGS/SYMPOSIA/SEMINARS

IUTAM-Symposium on Interaction Between Dynamics And Control In Advanced Mechanical Systems

Date: 21–26 April 1996
Place: Eindhoven, The Netherlands

Contact: Prof. D. H. van Campen
Chairman, Dept. of Mechanical Engineering
Eindhoven University of Technology
P.O. Box 513
NL-5600 MB Eindhoven, The Netherlands
Telefax: +31 40 447 355

IUTAM-Symposium on Innovative Computational Methods for Fracture and Damage

Date: 30 June–5 July 1996
Place: Dublin, Ireland

Contact: Dr. P. E. O'Donoghue
Chairman, Dept. of Civil Engineering
University College Dublin
Earlsfort Terrace
Dublin 2, Ireland
Telefax: +353 1475 4568

IUTAM-Symposium on Variable Density Low Speed Turbulent Flows

Date: 7–10 July, 1996
Place: Marseille, France

Contact: Professor L. Fulachier
Chairman, Institut de Mécanique Statistique de la Turbulence
12, Ave. Général Leclerc,
F–13003 Marseille, France
Telefax: +33 91 08 16 37
Phone: +33 91 50 54 39

Professor J. L. Lumley
Sibley School of Mech. and Aeros. Engin.
Upson and Grumman Halls
Cornell University
Ithaca, NY 14853, USA
Telefax: +1 607 225 12 22
Phone: +1 607 225 40 50

IUTAM-Symposium on Mechanics of Granular and Porous Materials

Date: 15–17 July 1996
Place: Cambridge, UK

Contact: Dr. N. A. Fleck
Chairman, University of Cambridge
Engineering Department
Trumpington Street
Cambridge CB2 1PZ, UK
Telefax: +44 1223 332 662
Phone: +44 1223 332 650

National Symposium on Polymers

Date: 26–27 February 1996
Place: Vallabh Vidyanagar

Topics include: Polymer synthesis and characterization; Polymer for specialized applications; Biodegradable polymers, environmental and ecological aspects of polymers; Polymeric dyes; Mathematical modelling in the field of polymers; Coordination polymers.

Contact: Prof. V. S. Patel
Coordinator, National Symposium on Polymers
Department of Chemistry, Sardar Patel University
Vallabh Vidyanagar 338 120
Phone: 02692–30411
Fax: 91–02692–46475

Introduction

David E. Bloom

Department of Economics, Columbia University, New York, NY 10027, USA
Harvard Institute for International Development, 1 Eliot Street, Cambridge, MA 01238, USA

The first case of HIV infection in India was detected in 1986 through a random blood test of a commercial sex worker in Madras. By late 1994, India's National AIDS Control Organization reported that nearly 51,000 HIV-positive people had been detected in the country, with 885 known cases of full-blown AIDS. Reported cases of HIV infection and AIDS, however, are only the tip of the iceberg and reflect little more than the limited amount of costly HIV testing that has been conducted. They are grossly misleading with respect to the extent of the epidemic, which needs to be estimated scientifically using statistical tools to infer the population level of infection from sample data. One such set of estimates recently prepared for India indicates that there are 900,000 to 2.1 million HIV-infected people in India, with 55,000 to 100,000 cumulative cases of AIDS. By the year 2000, the number of HIV infections is projected to grow to between 2.1 and 6.7 million people, with a cumulative total of 500,000 to 1.2 million cases of AIDS.

These statistics provide strong evidence that India is not immune to the rapid spread of HIV. It will not be spared because of its culture or through some ayurvedic or homeopathic cure. On the contrary, India is extremely vulnerable to the epidemic. Many factors contribute to its vulnerability: India's integration into the world economy; its changing social customs; its pockets of injecting drug use; its system of commercial blood supply; its medical practices; its large migrant population; its high level of illiteracy; and its age distribution, which has a large proportion of the population in the sexually active years.

AIDS is an unusual disease in modern times in that it is both incurable and invariably fatal. It is also unusual because carriers of HIV, the virus that causes AIDS, typically show no symptoms of the specific illnesses that define them as having AIDS for eight to ten years after they are infected. Thus, in its early stages, AIDS is an invisible disease. For this reason, in part, policy-makers are likely to be slow to react to the AIDS epidemic. It takes great wisdom, foresight and determination to address invisible problems, especially in the face of the many visible health problems, such as malaria, tuberculosis, hepatitis, cholera, typhoid and diarrhoea, which widely afflict many Asian populations. Responding to the AIDS epidemic is also complicated by the technical difficulty of establishing priorities for allocating resources to various health and other social problems, and by uncertainty about the appropriateness of particular policy and programmatic measures for HIV prevention and AIDS care.

Because of the disease's complexity in both biomedical and socioeconomic terms, no one discipline has a monopoly on the information and expertise needed to address the AIDS epidemic. Rather the response will have to draw upon skills and experiences from a wide range of fields, working cooperatively. This special issue of *Current Science* highlights this multidisciplinary complexity.

The nine articles that follow are divided into three groups. The first group provides essential background on HIV and AIDS, with John Dwyer discussing biomedical issues and James Chin describing the techniques for estimating and projecting HIV and AIDS cases from different sources of data. The second group describes the spread of HIV in Asia. Shiv Lal and B. B. Thakur provide an up-to-date review of the HIV and AIDS epidemic in India, while Rabin Sarda and George Peterson focus on the epidemic in the Western Pacific. Tim Brown and Werasit Sittitrai make the point that heterosexual sex is emerging as the dominant transmission category for HIV in Asia, and discuss salient features of the connection between risky heterosexual behavior and the epidemic.

The final group of articles addresses selected policy issues. Sherry Glied discusses the impact of HIV/AIDS from the perspective of the US experience, where nearly 300,000 people had died of AIDS by early 1995. Nandrani S. de Zoysa describes the Sri Lankan blood bank system and the measures it has adopted to safeguard the blood supply – almost entirely – from HIV contamination. Ronald Bayer discusses ethical considerations surrounding the issue of testing for HIV. Finally, Ajay Mahal and I discuss economic implications of HIV and AIDS and the potential contributions of economists to the design and implementation of policy and programmes in this area.

The authors hope that these articles will catalyse further research and discussion on the HIV and AIDS epidemic. India's natural and social science communities need to build momentum in their efforts to promote deeper understanding of the epidemic as a basis for the development of prevention and care strategies that are rooted in local realities. If the Indian epidemic continues along its present trajectory, the consequences could be disastrous. India must act now, so that it does not look back ten years from now with sorrow and regret upon 20 million HIV-infected Indians.

*I would like to thank the United Nations Development Programme's Regional Project on HIV/AIDS for supporting the publication and distribution of this special issue. I would also like to thank Preeti Sinha, Ajay Mahal and Uma Kurup for their advice and assistance throughout the project.

Biomedical aspects of HIV and AIDS

John M. Dwyer

Division of Medicine, Prince of Wales Hospital, Randwick, NSW 2031, Australia

IN 1981 reports of immunodeficiency associated with the development of pneumocystis carinii pneumonia in homosexual men on both the East and West coasts of the United States brought to the world's attention the beginning of what is now referred to as the AIDS epidemic[1]. Previously healthy men had, for no apparent reason, acquired an immune deficiency state that was so serious that they could no longer protect themselves from usually readily dismissed organisms such as pneumocystis carinii. Physicians in the Western world had not encountered such a syndrome before. Because the new disease initially affected homosexual men, concepts of a "gay plague" became popular and much effort was expended on looking for unique features of the homosexual life-style that might destroy immunological competence. Any retrospective review must realize that no knowledge of the epidemic of AIDS that had been sweeping through Africa for at least thirty years was available to help clinicians understand the disease they were now seeing in the West.

With the discovery that the human immunodeficiency virus (HIV) was responsible for destroying the immune system and producing AIDS[2] the pandemic nature of the problem became clear. At this writing, the World Health Organization's Global Programme on AIDS estimates that some eighteen million adults and one-and-a-half million children are infected with HIV and that between 5000 and 10,000 individuals are infected every 24 hours[3]. In 1994 more than three million adults became infected with the virus. The epidemic continues to spread at ever faster rates in many developing countries, with the epicentre of the epidemic moving inexorably from Africa to Asia. Already, India may have more individuals infected with HIV than any other country. This review will examine the biomedical aspects of HIV infection that are producing much individual human suffering and socioeconomic disruption in many countries.

Virology

Only in the last fifteen years have investigators realized that members of the retroviral family of viruses are capable of producing disease in humans[4]. Prior to that time the medical community had known that these viruses could produce disturbances of the immune and nervous systems of animals, with the immunodeficiency produced often being associated with some form of malignancy. A competent immune system is necessary to protect us from certain forms of cancer. We now know that one distinct branch of the retroviral family can produce leukaemia in humans while another branch of the family contains two viruses, HIV-1 and HIV-2, that can destroy the most important, indeed pivotal, cells within the immune system: CD4 lymphocytes. These cells are members of the T cell family of lymphocytes produced in the thymus gland. While the destruction of sufficient numbers of CD4 lymphocytes to produce immunodeficiency takes a number of years (there are approximately six hundred billion of such cells available to an adult), a threshold is reached when there are simply too few of these cells available to protect an individual from invading microorganism and the clinical syndrome AIDS develops.

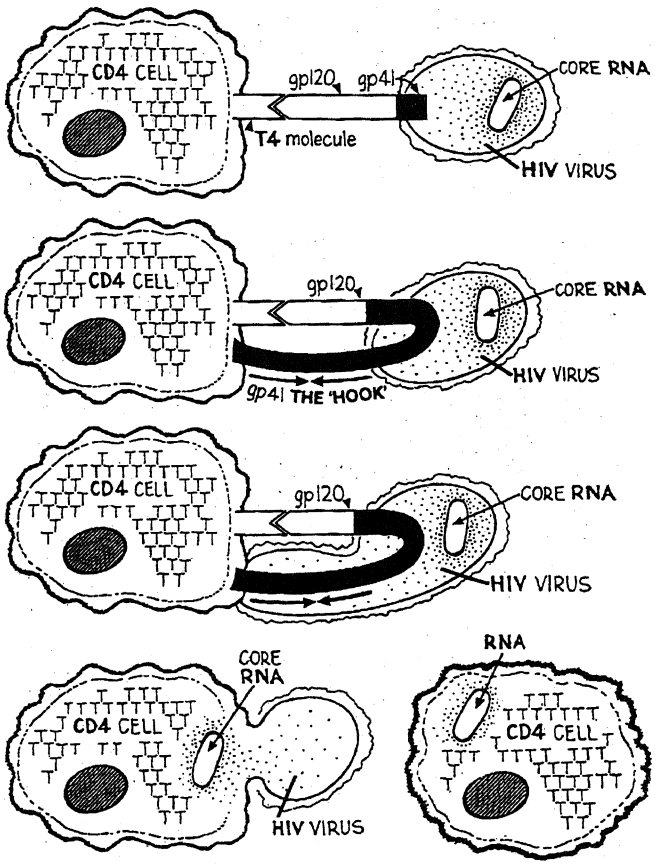

Figure 1. The binding and fusing of HIV to CD4 cells.

Retroviruses are composed of RNA and to reproduce must insert their genetic information into the DNA of the nucleus of the cell they invade. To accomplish this, they carry with them a unique enzyme, reverse transcriptase, that once activated inside a parasitized cell can translate RNA into DNA. It is this 'turning' from RNA into DNA that gives the family its name ('retro'). The virus is composed of an envelope from which protrude unique three-dimensional structures contained within a large molecule (molecular weight (MW) 120,000 Da) (Figure 1). This protein, gpl20, allows HIV to bind with exquisite specificity to a molecule present on the surface of CD4 thymus-derived lymphocytes. These cells are involved in initial recognition of 'foreignness' i.e. antigenic determinants which are recognized in the form of small amino acid sequences. CD4 lymphocytes do not react to self-determinants but do react to foreignness, initiating a cascade of immunological responses that ultimately lead to the elimination of non-self protein[5]. Currently, we recognize two distinct forms of CD4 lymphocyte. THE cells can stimulate cells referred to as CD8 lymphocytes (also derived from the thymus gland) to destroy directly or help produce an inflammatory response to viral, fungal and parasitic invaders. The second type of CD4 lymphocyte (TH2 cells) activate bone-marrow-derived lymphocytes, 'B cells', to produce antibodies that are essential for the elimination of extracellular bacteria[6].

Because CD4 lymphocytes play a pivotal role in initiating an effective immune response, the invasion and destruction of these cells by HIV-1 and HIV-2 cripples the entire immune apparatus.

As mouse lymphocytes into which the genes for the CD4 molecule have been inserted cannot be infected with HIV-1 or HIV-2, despite the resulting expression of the CD4 molecule on their surface, researchers have long argued that a second receptor is necessary for HIV invasion of lymphocytes. Recently scientists at the Institute Pasteur in Paris have suggested that the second molecule is CD26, a widely distributed protein present on many cells including CD4 lymphocytes[7].

A transmembrane protein in the envelope of HIV-1 and HIV-2 referred to as gp41, as it has a molecular weight of 41,000 Da, is capable of fusing the envelope of HIV with the membrane of a CD4 lymphocyte that has bound the viral receptor molecule gpl20. With the fusion of the two membranes, the core of HIV finds itself in the cytoplasm of the attacked CD4 lymphocyte. Activation of reverse transcriptase, insertion of proviral DNA and the subsequent replication of HIV within the T cell leads to both replication of the virus and the destruction of that particular T lymphocyte[8].

An addition to specific genes that code for the production of the viral envelope or the RNA sequences needed for replication and reverse transcriptase, HIV-1 and HIV-2 contain a series of genes that produce regulatory proteins. While some of the products of these genes may be directly toxic to CD4 lymphocytes, their major role is to activate and control the replication of HIV in an infected cell. These regulatory genes are potential targets for therapeutic intervention strategies. Thus, HIV has a unique capability to invade and destroy thymus-derived CD4 lymphocytes, thereby producing, over an extended period of time, such a gross immune deficiency that infected individuals can no longer limit the replication of HIV or respond effectively to other infectious agents that take the 'opportunity' presented to them to produce serious clinical disease.

Immunology

Infection with HIV produces, within six weeks, an effective immune response that limits the initial burst of viral replication. An effective response involves the production of neutralizing antibodies but, more importantly, the activation of CD8 lymphocytes that can destroy virus-infected cells and/or secrete an as yet uncharacterized lymphokine that inhibits viral replication. Lymphokines are hormone-like chemicals produced by activated lymphocytes to carry activation and suppressive signals from one cell involved in an immune response to another. Patients infected with HIV, though infectious, remain well for a number of years after infection occurs as a result of this immune response. No evidence exists to date to suggest that the immune response of anybody infected with HIV has successfully eliminated the virus or produced an immunological response that would make one confident that AIDS will never develop. While 67% of patients infected with HIV will have developed AIDS within ten years of infection, those that stay well longer are currently being investigated to determine if they make a more effective immune response to HIV than those who are ill at the end of ten years of infection.

Within a few weeks of infection the number of CD8 lymphocytes present in the circulation of people infected with HIV increases markedly. Most of the CD8 lymphocytes belong to that subclass of thymus-derived lymphocytes that are capable of attacking virus-infected cells. The total number of circulating CD4 lymphocytes usually undergoes an initial and significant fall around the time of seroconversion before stabilizing for many years. The replication of the virus in the first few weeks of infection is associated with permanent destruction of a significant number of CD4 lymphocytes.

HIV is cleared from the plasma of an infected individual at the time of seroconversion as antibodies remove the virus present and CD8 lymphocytes minimize further production. From then on, finding viral proteins in serum or indeed in peripheral blood lymphocytes becomes difficult. Thus, while it is possible throughout the course

of an active infection with the hepatitis B virus to find viral protein in the blood stream, we rely on the presence of antibodies to HIV to diagnose the presence of that virus. We now know that most of the infected CD4 lymphocytes pool rapidly within the lymphoid tissue of infected individuals. Lymphoid tissue is organized into nodes or glands that are scattered around the body at critical sites. The immune system prefers to fight its immunological battles in these highly organized centres. It is probable, but not established, that this pooling is associated with activation of signals that attract HIV-infected cells into lymphoid tissue. Certainly, a significant number of patients rapidly develop lymphadenopathy (swollen lymph glands) and recent studies strongly suggest that the destruction of most of CD4 lymphocytes by HIV-induced mechanisms occurs in lymphoid tissue rather than in the circulation[9].

Ultimately, the immune system's effectiveness in controlling HIV is compromised because of the ongoing destruction of more and more CD4 lymphocytes. Some four to five years after initial infection, some selective process, as yet uncharacterized, commonly seems to destroy THE CD4 lymphocytes more rapidly than those capable of stimulating an antibody response (TH2 cells). Thus, although the number of CD4 lymphocytes in the circulation may remain relatively stable, the number of cells capable of stimulating an effective cell-mediated immune (CD8) response continues to fall. This dramatic change in the immunobiology of the natural history of the disease is not associated with changes in an infected individual's clinical state.

Numerous reasons are known to be associated with the virus's capacity to evade an effective immune response and ultimately, in most cases studied, destroy effective immunity. HIV can destroy cells that are not directly

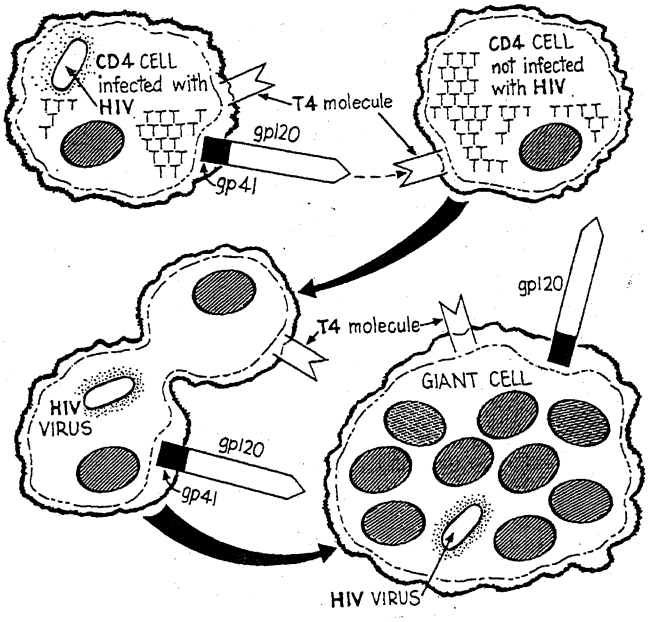

Figure 2. Two indirect methods used by HIV to kill CD4 cells.

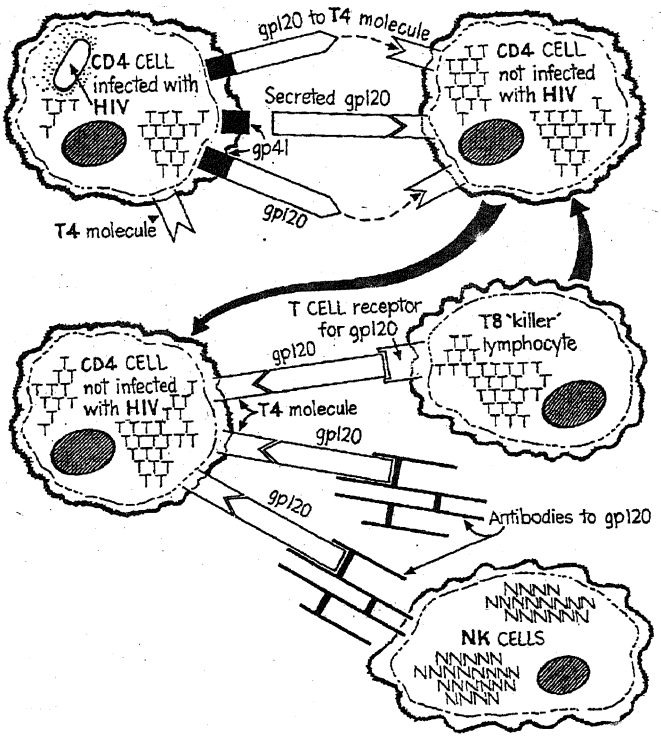

Figure 3. Normal CD4 (T4) cell destroyed by antibodies, NK or T8 cells because it bound secreted gp120.

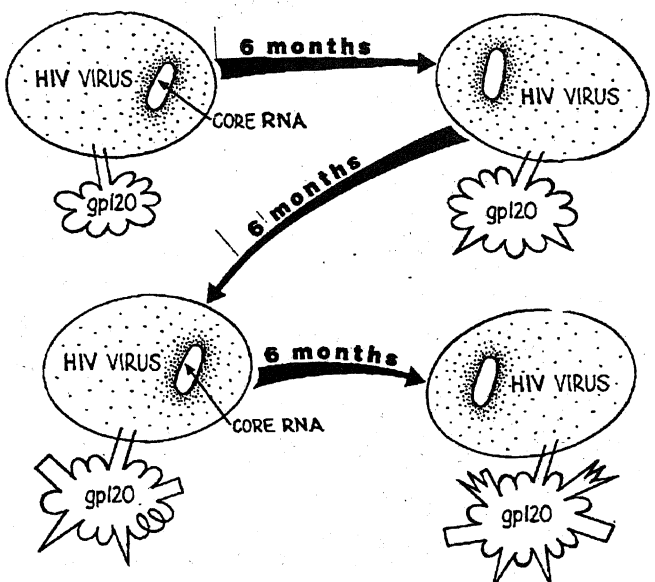

Figure 4. HIV changes the structure of its envelope (coat) to confuse attacking T8 cells.

infected with HIV at all (Figure 2). In cells infected with HIV in which the virus is actually replicating, envelope proteins (gp120 and gp41) are expressed on the surface of the cell, thus enabling an infected cell to bind the CD4 molecule of passing uninfected lymphocytes (Figure 3). As these envelope proteins contain the fusigenic moiety (gp41), giant cells (or syncitia) are formed. gp41 fuses the outer membrane of the T cell to the coat of the virus. At the

point of contact the contiguous membranes dissolve and in this way the core of the virus finds itself inside the CD4 lymphocyte. By the formation of these giant cells as infected cells trap uninfected cells it is possible for one infected cell to kill five hundred uninfected cells.

The secretion from infected cells of envelope proteins that will bind to CD4 molecules present on uninfected cells sets these unfortunate cells up as targets for cellular and humoral responses generated against envelope proteins. In addition to these strategies HIV-1 and HIV-2 are capable of generating considerable antigenic diversity among their envelope proteins. This constant antigenic 'drift' interferes with the perpetuation of an effective secondary immune response and requires the constant reactivation of primary immune responses to handle the variations presented to the immune system.

Clinical considerations

Infected CD4 lymphocytes, rather than free virions (elementary virus particles), are the important vector for HIV in human to human transmission. HIV-containing CD4 lymphocytes in sufficient concentration to make a biological fluid infectious are found in breast milk, blood and the sexual secretions of males and females. HIV can thus spread from an infected to an uninfected individual during vaginal or anal intercourse if infected blood from one individual enters the body of another and occasionally during breast feeding, particularly if a mother is in an early or very late stage of infection. At both extremes the replication of virus is most rapid and the concentration of virus in biological fluids reaches highest levels.

Within four to six weeks of infection, a seroconverting illness is noted by many, but these flu-like symptoms may not be particularly dramatic and are frequently not remembered by infected individuals. The symptomatology, which may occasionally feature significant pain associated with a neuropathy, is transient, and after it disappears many years may pass before an individual has any significant symptoms referable to HIV infection. Lymphadenopathy develops in 30–40% of infected individuals and this in itself is not a bad prognostic sign. As noted above, within ten years of infection with HIV, 67% of infected individuals have so many CD4 lymphocytes destroyed that they develop that ultimate complication of HIV infection: AIDS.

Prior to the development of AIDS, two HIV-related complications are common. The first is Kaposi's sarcoma, which is a tumour-like proliferation of the endothelial cells lining blood vessels[10]. The lesions often begin in the skin, although they are frequently first recognized in the mouth, particularly on the hard palate. The proliferation of these cells can occur within internal organs. Kaposi's sarcoma probably occurs when an as yet unidentified sexually transmitted cofactor stimulates endothelial cells to release cytokines which perpetuate the proliferation of these cells. Cytokines are like lymphokines, that are hormone-like substances released from cells, but in this case the chemicals referred to are released by cells lining blood vessels rather than lymphocytes. It is the limitation of Kaposi's sarcoma to homosexual men infected with HIV in the West that has led many to suggest that a sexually transmitted cofactor must be involved.

Kaposi's sarcoma can be cosmetically disfiguring but harmless, or can involve lymphatic tissue and produce gross swelling, particularly in the lower limbs and scrotum, and become a major clinical problem. Frequently, it displays a propensity for the nose and eyelids. Small lesions often respond to radiotherapy, but chemotherapy may be required if lesions are producing secondary phenomena of consequence.

The second complication is that some 10–20% of patients develop a presenile dementia prior to the development of AIDS. Initially, higher-centre functions are affected, such as concentration and judgment, and these defects can be measured using psychometric analysis. Antiretroviral therapy with AZT can minimize the symptoms of HIV-related dementia if introduced into the management of the condition soon after the onset of symptoms. This complication seems to be caused by certain strains of the virus that infect macrophages that transport the virus to the brain and then subsequently release cytokines that damage delicate nervous tissue. Macrophages are scavenger cells of the immune system and certain variations within the virus itself seem to make it easier for certain macrophages to swallow viral particles and transport them to the central nervous system.

Prior to the development of AIDS, as viral replication becomes more efficient, accelerated T cell destruction occurs, and patients may develop a period of weight loss characterized by profuse sweating at night and the development of a fungal infection in their mouth with *Candida albicans*.

CD4 lymphocytes are usually present in the blood in numbers greater than 700 µl. When the number falls to 200 µl or less, patients are at risk of developing opportunistic infections, which lead to the definition of AIDS in an individual case. Pneumonia produced by *Pneumocystis carinii* is the most common AIDS-defining illness. Toxoplasmosis, *Cryptococcus neoformans* infection (usually of the central nervous system), atypical and typical tuberculosis (the latter increasingly drug-resistant) and problems associated with cytomegalovirus are some of the most common serious infections noted. Once AIDS develops, patients usually survive no longer than two years even when the most sophisticated treatment is available.

Antiretroviral therapy

While numerous drugs to help manage HIV infection are in various stages of development, only one family of

drugs have so far been shown to be successful and relatively safe after extensive clinical trials. AZT was the first drug developed that could inhibit the replication of HIV effectively. As with all of the drugs that are currently available, AZT works by interfering with reverse transcriptase and by interfering with the successful transcription of viral DNA into viral RNA. Recent studies reveal that none of the currently available antiretroviral agents are effective long-term, as in most patients, viral mutations lead to drug resistance within 12–18 months. This appears to be true whether monotherapy or combination therapy is used. Strategies being studied now involve the rotation of various retroviral agents on a regular basis and the introduction of new drugs which attack viral replication at different stages of the virus's life cycle.

Vaccines

To date no vaccine has been developed that can prevent infection with HIV in humans or chimpanzees, the only animal besides humans that can be infected with HIV-1 or HIV-2. Although clinical trials in humans of preventative vaccines have started, no clinical data related to their efficacy is as yet available. Somewhat dishearteningly, evidence suggests that the vaccines used to prevent the infection of monkeys with a simian immunodeficiency virus (SIV) infection have been ineffective. Certain monkeys infected with that virus develop AIDS. Epidemiological investigations in the last twelve months have noted the emergence of more and more new strains of HIV in various parts of the world. There are now more than nine major variations on a theme which will make it extremely difficult to produce a vaccine that will be equally effective in different parts of the world. The difficulty in producing a cheap effective vaccine highlights the need to reemphasize preventative strategies. Because preventing infection is proving to be so difficult, many scientists have turned their attention to preventing disease. HIV infection does not produce significant clinical consequences in the first few years of infection. If the initially adequate immune response could be so strengthened that HIV replication is permanently minimized, then HIV infection may be no more serious than infection with the virus responsible for chicken pox. That virus is never eliminated from the body, but after an initial flourish rarely causes further problems. Therapeutic vaccines have been developed and are being tested in an attempt to introduce to a competent immune system viral envelope and core variations that the immune system may encounter at a later date during the course of HIV infection. While it is too early to judge the success of this strategy, on theoretical grounds it seems to be likely to produce more immediate benefits than any other therapeutic strategy currently being developed.

Summary

Two distinct members of the retrovirus family, HIV-1 and HIV-2, can selectively destroy CD4 lymphocytes in humans, and thus over a period of ten years can induce a degree of immunodeficiency that allows opportunistic infections and the development of malignancy to kill infected individuals. Envelope proteins developed by the virus provide numerous mechanisms for the destruction of immunologically competent cells. 80% of infections occur during vaginal intercourse, with blood-to-blood transmission being responsible for most remaining infections. At this time, anal intercourse is responsible for less than 10% of infections worldwide. No effective vaccine to prevent infection is likely to be developed within the next ten years. Prevention must remain the major goal of all public health officials, or the World Health Organization's prediction that 30–40 million people will be infected by the year 2000 may turn out to be a significant underestimate. Antiretroviral drugs and therapeutic vaccines offer the best hope in the immediate future for prolonging quality life in people infected with HIV.

Estimation and projection of HIV infection and AIDS cases

James Chin

Division of Epidemiology, University of California, Berkeley, School of Public Health, Department of Biomedical and Environmental Health Sciences, 456 Kentucky Avenue, Berkeley CA 94707, USA

HOW many HIV infections and AIDS cases have occurred in the past, are currently present, and are likely to occur in the future? Reliable answers to these questions are needed to evaluate the spread of HIV and AIDS and to help plan public health, health care, and social welfare programmes vital for an appropriate response to this ever-expanding pandemic. However, since the early 1980s, when AIDS was first recognized, the pandemic's future trends and ultimate dimensions have been shrouded in uncertainty. This uncertainty persists because of the difficulties in measuring the prevalence, and especially the incidence, of AIDS cases and HIV infections in a given population with any substantial degree of precision. As a result, investigators have used many methods and models in attempts to understand the dynamics and interrelationships of the major determinants of HIV transmission and develop reliable estimates and projections of HIV and AIDS. The methods and models used need to be examined critically and understood before their outputs are accepted and used for public health programmes or policy decisions. This paper provides an overview of the uses and limitations of the methods available for HIV and AIDS estimates and projections. These methods are listed in Table 1.

Public health surveillance data[1–12]

Virtually all countries collect data on AIDS cases, primarily through public health surveillance systems that rely on passive notification of case reports. Reports of AIDS cases from industrial countries of Europe, North America and Oceania have been, up to 1993, based primarily on the 1987 Centers for Disease Control/World Health Organization (WHO) case definition[1]; those from Africa have generally been based on nationally adapted versions of the WHO clinical (Bangui) definition[11]; several countries in Latin America have used the Pan American Health Organization's Caracas definition[6]; and those from other countries involve a combination of these definitions. In addition to the problem posed by varying definitions of AIDS cases, the data are flawed by significant problems related to the wide variations found in the accuracy, completeness and timeliness of different national AIDS reporting systems. However, reported AIDS case data can provide the basis for estimating the actual number of cases that may have occurred. Researchers have prepared such estimates by adjusting reported AIDS data to correct for delays, inaccuracies and incompleteness. However, these adjustments require specific studies to determine the precise degree of correction needed for each limiting factor, and many estimators assume erroneously that these factors do not change with time. Hence, the reliability of AIDS estimates derived after such adjustments varies.

Detection of HIV infection became possible with the development of HIV antibody tests, which were first available in 1985. Most public health surveillance data on HIV infection have been obtained from a variety of uncoordinated sources, and much of the data were gathered from samples of selected population groups. Thus, data obtained from different areas or studies are usually not

Scenario/modelling approach

comparable. Current serological tests for detecting HIV antibodies are reliable for measuring HIV prevalence in populations: collectively they have shown that HIV infection is not randomly distributed in a given population. Relatively high prevalence rates (from a few per cent to more than 50) can be found among homosexual or heterosexual individuals who have had multiple sexual partners and those people who share drug injection equipment. The prevalence of HIV infection in most general populations of industrial countries is low and may range from almost zero to one per several thousand.

Researchers have estimated HIV prevalence most often by using the results of serological surveys and extrapolating the data to specific populations. Major problems with this method are the limited number of seroprevalence studies that are representative of specific populations or subgroups, and the wide variability in estimates of the size of important subgroups, such as female prostitutes, injecting drug users, and patients seen in sexually transmitted disease clinics. Nevertheless, investigators have derived reasonable working estimates of the prevalence, general distribution, and trends of HIV infection for many countries by analysis of all available HIV serosurvey data.

In the mid- to late-1980s, with only limited HIV data available, investigators tended to overestimate HIV prevalence for many areas and populations. In the United States for example, during the period 1985–1992 official estimates of cumulative HIV infection remained consistently in the range 1.0–1.5 million. As of early 1995, the best estimate of cumulative HIV infections was still between 1.0 and 1.5 million, which clearly indicates that all previous estimates were too high. In the United Kingdom in the mid-1980s HIV prevalence was estimated at 80,000. Subsequent reviews and analyses of the accumulating HIV data by expert committees resulted in a consistent downward revision of this estimate to a maximum of about 30,000. In 1987, WHO's estimate of global HIV infection ranged from 5 to 10 million. With the collection and analysis of more recent HIV data (primarily from sub-Saharan Africa) WHO's revised 1990 estimate of global HIV infection was reduced to the lower level of the 1987 estimate, i.e. about 5–6 million. Since the late 1980s, WHO's global and regional HIV estimates have been intentionally conservative.

The Delphi survey method[13–15]

The Delphi survey method was developed in an attempt to improve the reliability of the judgments needed in relatively uncertain situations and to provide a means of quantifying such judgements. This method was originally systematized in the 1960s for use in developing management policies. It was first applied to the health field in the 1970s. Essentially, the Delphi method obtains educated guesses from selected experts in a reiterative fashion, and then uses the average and range of the Delphi responses as projections. Major advantages of the Delphi method are speed and low cost. However, it is difficult to select truly knowledgeable experts to estimate the number of HIV infections and AIDS cases. Furthermore, estimates and projections made by the Delphi method may have extremely wide ranges.

In 1988 WHO used a Delphi survey to obtain projections of HIV prevalence. Delphi survey respondents projected that there would be 15–20 million cumulative adult HIV infections worldwide by the year 2000. Yet shortly after that survey, HIV serological data for sub-Saharan Africa and southeast Asia showed marked increases in HIV seroprevalence. These increases, estimated at about 5 million new infections within two to three years after the survey, suggested that the 1988 Delphi projections were too low. In 1991, based on observed HIV trends, WHO projected that a cumulative total of 30 to 40 million HIV infections would occur in men, women, and children by the year 2000.

In mid-1992 a Harvard group, AIDS in the World (AIW)[15], also carried out a Delphi survey to project cumulative global HIV infections by the year 2000. While AIW's low Delphi total was only slightly higher than WHO's conservative projection in 1991, its high Delphi projection, more than 100 million cumulative HIV infections by the year 2000, was three to four times higher than their low Delphi projection. With the exception of AIW's high Delphi projection (for which no comparable WHO projection was made) the independent estimates and projections of HIV infections and AIDS cases were reasonably close to WHO's projections. AIW did not select either the low or high Delphi projection as their best estimate for the year 2000, but most references to its Delphi projections focus on their high Delphi projection.

How plausible are AIW's high Delphi projections? If cumulative infections in North America (primarily the United States) were estimated to be about 1.2 million as of 1993, then almost 1 million new HIV infections would have to occur each year in North America to reach AIW's high Delphi projection of more than 8 million. Similarly, in sub-Saharan Africa, more than 3 million new HIV infections would have to take place annually to reach the projected total of more than 33 million by the year 2000. For other regions, the AIW's projections require new HIV infections of about 1 million per year in Latin America, close to 1 million per year in the Caribbean, and almost 6 million per year in southeast Asia to reach 45 million by the year 2000 (Table 2). None of these annual incidences are plausible based on observed HIV data and trends, which suggest that with the exception of southeast Asia, which is still at an early stage

Table 2. AIDS in the world: HIV estimates and Delphi projections (millions)

Region	Cumulative estimate Jan 1992	Cumulative estimate Jan 1993	High Delphi projection by the year 2000	Annual incidence needed from 1993 to 2000
North America	1.167	1.261	8.150	0.984
Western Europe	0.718	0.834	2.331	0.214
Sub-Saharan Africa	7.803	10.985	33.609	3.232
Southeast Asia	0.675	3.567	45.059	5.927
Latin America	0.995	1.050	8.554	1.072
Caribbean	0.310	0.461	6.962	0.929
Total	11.799	18.311	104.665	12.336

in its HIV epidemic, the highest annual HIV incidence in most other regions may have already occurred.

HIV and AIDS models

Researchers have developed many types of HIV and AIDS models in attempts to understand the dynamics of HIV spread and to develop reliable projections of the epidemic's eventual extent. The major components of all models include the basic assumptions and input parameters used, the value or range of values for the input parameters, and the mathematical interrelationships between the parameters used in the model. The results produced by any model should not be used to formulate programmes or make policy decisions unless those making such decisions fully understand and agree with the basic assumptions, the values used for the input parameters and the mathematical interrelations between the input variables.

HIV and AIDS models can be broadly classified into three types that range from the simplest to the most complex. The first two types are empirical, extrapolation models, while models of the last type have been described as explanatory or deterministic. In general, the simpler extrapolation models are designed for short-term projections and the more complex models for evaluating determinants of the HIV and AIDS pandemic and for hypothesis testing.

Type I models[16–18]

Type I models use reported AIDS case data to make short-term (two to three years) projections of AIDS cases. Such short-term projections have been made by statistical extrapolation and regression techniques applied to the observed temporal curve of the reported AIDS cases. These models assume that after adjusting for reporting delays (and in some models for incomplete reporting), the trends of reported cases during the next few years will remain essentially similar to those observed in the recent past. A profusion of such models has been described, but a major problem with these models is that many mathematical curves can fit the data equally well. Not only is there no way to choose the best among the various curves, but the fitted curves may lead to widely divergent projections, particularly if they are used to make projections for periods longer than two to three years. Type I models should be used only to project AIDS cases two to three years ahead, and only for populations for which AIDS case reporting is relatively timely, reliable and complete.

Type II models[19,20]

Type II models use the data on estimated HIV infections and progression rates from infection to AIDS to calculate the number of past AIDS cases and to provide short-term (three to five years) projections of AIDS cases. A variation of this approach is the back calculation method, which uses AIDS case reports in conjunction with annual progression rates from infection to AIDS to estimate the number of annual HIV infections that have occurred. This method requires relatively accurate, complete and timely reporting of AIDS cases. However, because few people develop AIDS within two to three years of infection, this method cannot be used to estimate HIV infections that occurred during the prior two to three years even in areas where AIDS case reporting is considered reliable.

A simplified variation of this method uses an estimated ratio of HIV infections to AIDS cases to calculate total HIV infections. Like back calculation, this ratio method requires reliable estimates of AIDS cases, which are not available in most developing countries. In addition, users of the ratio method must realize that the ratio of HIV infection to AIDS cases changes rapidly with time. The ratio falls from many thousands to one during the first few years of extensive HIV spread in a population to less than ten to one after the first decade. This decline occurs whether HIV incidence is increasing or decreasing because a substantial proportion of HIV-infected individuals progress to AIDS as long as 10 to 20 years after contracting HIV infection.

Type III models[21–26]

Type III models are more complex and incorporate biological and behavioural variables that describe the transmission and natural history of HIV infection so as

to simulate the entire disease process. Many mathematically sophisticated type III models have also been developed to project the future course of HIV and AIDS epidemics in different areas and populations. These complex models usually use differential equations to describe biological and behavioural variables known to be important in the transmission and progression of HIV disease in their simulation of the process from infection to progression to AIDS and death.

These deterministic or simulation models include: the mathematical model(s) of Anderson *et al.*[21]; the demographic model developed by Bulatao of the World Bank[25]; a Monte Carlo type model ('Simulaids') developed by Auvert *et al.*[22]; (1990); and an extremely detailed model – the interagency working group model – developed principally by Stanley and Seitz[26]. These models require, in varying degrees, extensive data sets on virtually all the demographic, biological and behavioural variables considered to be important in the epidemiology and natural history of HIV infection. The major problem with these models, aside from their complexity, is that most of the precise, detailed data sets they require to make projections are not available, even in those countries with the best data collection systems.

Most complex type III models have used hypothetical populations to obtain projections. In an exercise for which the population characteristics and a defined set of variables and input values were provided, a group of models produced widely varied, long-term demographic projections for HIV and AIDS. Projections for the percentage of the adult population infected with HIV in the year 2010 varied from a high of almost 40% in one model to a low of less than 3% in another. The greatest value of complex mathematical models may well be in their use to test hypotheses rather than for estimation and projection of HIV and AIDS prevalence.

A scenario/modelling approach

Given that predictions by complex models appear to be of doubtful validity, and because no criteria exist to select a good or best HIV and AIDS model (especially for projecting future HIV incidence and prevalence), a simpler scenario/modelling approach for estimation and projection of HIV infections and AIDS cases was developed by the author when he was at WHO during the late 1980s. The scenario/modelling approach can be used in individual countries and for selected populations within countries to provide working estimates and short-term projections of HIV-related morbidity and mortality for purposes of policy development and public health planning.

A scenario is defined as an outline of any series of events, real or imagined. Plausible HIV scenarios can be constructed from available HIV data and observed trends. Because future AIDS cases and deaths depend on the number and pattern of HIV infection and progression rates from infection to severe disease and subsequent death, AIDS cases and deaths can be calculated for different HIV prevalences and patterns (HIV scenarios) based on simple assumptions about the occurrence of these events.

The general methods used in the scenario/modelling approach to develop working estimates and projections of HIV and AIDS are as follows:

* The most recent patterns, prevalence and trends of HIV infection in specific population groups are estimated from an epidemiological analysis of all available HIV data. The HIV database compiled by the Center for International Research, US Bureau of the Census, is a valuable data source. Unpublished national HIV data, when available, should also be used to supplement these data.
* Based on these data and other epidemiological observations, different HIV scenarios can be estimated and projected to the year 2000 or beyond for major geographical and epidemiological regions. Optimistic or best-case scenarios should be constructed to derive conservative estimates and projections for public health planning.
* EPIMODEL, a relatively simple type II AIDS model developed by the author when he was with the WHO's Global Programme on AIDS can be used to estimate and project AIDS cases and deaths based on the HIV scenarios.

The reliability of HIV and AIDS projections obtained by this scenario/modelling approach depends primarily on two factors: the accuracy of the estimated number of HIV-infected people, and the proportion of HIV-infected people who ultimately develop AIDS.

The estimates and projections obtained from this scenario/modelling approach need to be modified as additional data on HIV prevalence and progression indicate that changes are warranted. However, health and social welfare systems should use conservative estimates and projections derived by this method to plan for and develop the resources needed to respond to the minimum number of HIV-related disease and deaths that can be expected during the remainder of this decade.

Summary and conclusions

The answer to the opening question 'How many HIV infections and AIDS cases have occurred, are currently present, and will occur in the future?' is that we really do not know, but we can estimate and project these numbers with varying degrees of uncertainty. Our ability to estimate past and current numbers is improving as public health surveillance systems collect more data.

Although the accuracy of such estimates varies greatly depending upon the quantity and quality of the surveillance data, plausible minimum, maximum and mid-range working estimates can be developed for use by public health and health care programmes.

Projection of future patterns and prevalence of HIV and AIDS is more difficult, but such projections or scenarios are essential to begin planning programmes to respond to the increasing number of premature deaths among young and middle-aged adults because of AIDS. A conservative HIV and AIDS scenario can be constructed from data on current global status and trends of regional epidemics. According to this scenario a cumulative total of about 40 million men, women and children would have been infected with HIV by the year 2000, with more than 90% of this total occurring in developing countries. By understanding the uses and limitations of all available methods and models that have been used for forecasting HIV and AIDS epidemics, such scenarios can assist policy-makers and social welfare and health care planners to prepare for the projected numbers of AIDS deaths and AIDS-related orphans.

The problem of HIV and AIDS in India

Shiv Lal and B. B. Thakur

National AIDS Control Organization, Ministry of Health and Family Welfare, IRCS Building, 1 Red Cross Road, New Delhi 110 001, India

ALTHOUGH the AIDS pandemic is in its early stages in Asia, the virus is spreading rapidly among high-risk groups and is making fast inroads into the general population. Estimates suggest that more than one million people are infected with HIV in India[1].

India is a large country in terms of area and population, so the epidemic's spread and impact have not been homogenous . There are many regional and population group variations, which probably reflect separate epidemics with their own starting points and probably involve different types and frequencies of risky behaviours and practices, such as having multiple sex partners or sharing drug injection equipment.

The situation in India

HIV was first detected in India in 1986 when pilot HIV surveillance activities were carried out among selected populations and in various locations to ascertain if the virus was present in the country. Within six or seven years, it became evident that HIV infection was present in almost all parts of the country, but was worst in the states of Maharashtra, Tamil Nadu and northeastern States of Manipur, Mizoram and Nagaland. In the latter three states, which border Myanmar, the main mode of HIV transmission is through needle sharing by injecting drug users[2], whereas in the rest of the country, most infections are transmitted through heterosexuals[3]. The number of AIDS cases reported from all parts of the country is increasing.

AIDS cases

In 1986, Bombay reported India's first AIDS case. Since then, as of 31 January 1995, a total of 1032 AIDS cases have been reported to the National AIDS Control Organization from the states and union territories as shown in Table 1 (ref. 4).

As is true elsewhere, the number of reported cases in India represents a small fraction of actual AIDS morbidity. This gap between actual and reported cases is caused by both underreporting and misdiagnosis; as the medical community's awareness and training improve, the gap is likely to shrink. According to estimates based on HIV prevalence, the actual number of AIDS cases in India is probably between 10,000 and 20,000 (ref. 5). However, the number of AIDS cases in the country cannot be taken as indicative of the current HIV and AIDS problem because the number of current AIDS cases reflects the HIV situation that prevailed five to ten years ago.

HIV infection

From October 1985 until the end of January 1995, about 2,443,141 individuals had been tested for HIV through the nationwide surveillance, of whom 17,283 tested positive for HIV (ref. 4). HIV prevalence increased from 2.5

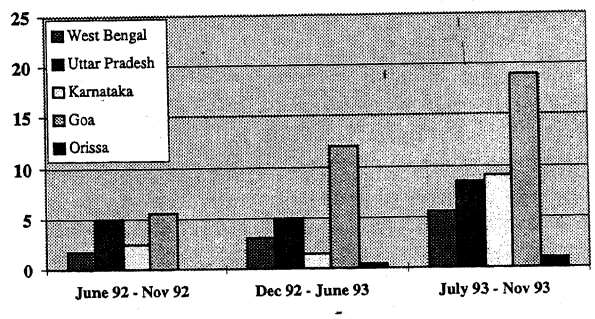

Figure 1. Prevalence of HIV infection in selected states (June 92–November 1993).

per 1000 population in 1986 to 11.2 per 1000 by 1992. The course of the epidemic has been quite varied in nature, as is reflected clearly by Figure 1. Most of this testing has been done on population groups perceived to be at high risk for HIV infection; this may influence the results. The data available to date indicate not only that the infection is present in all regions but also that it has spread well beyond the high-risk groups to the general population.

The HIV prevalence rate varies widely in different areas and among different population groups. The major concentration of infection remains in the city of Bombay, where HIV prevalence among prostitutes has risen significantly, from 10% in 1986 to 51% in 1993. The other known centres of HIV infection are Madras, Madurai, Pune, Vellore and the surrounding areas. In Vellore, the HIV rate among prostitutes increased from 0.5% in 1986 to 34.5% in 1990. The latest sentinel surveillance data (1993) from Madurai and Madras showed that the prevalence of HIV infection among attendees at clinics for sexually transmitted diseases is 6.5% and 2.7%, respectively. Other studies have shown that HIV prevalence among injecting drug users increased from some 45% in the first half of 1992 to 73% in the first half of 1993.

The increasing trends of HIV infection among the high-risk groups have been followed closely by the rising trends among the general population. The sentinel surveys done among pregnant women in Bombay, Salem and Manipur have found the prevalence of HIV to be 2.5%, 1.1% and 0.8%, respectively (Figure 2). The prevalence among pregnant women in Tirupati rose from 0.5% in 1990 to 2.0% in 1993. Such trends demonstrate the spread of HIV infection in the general population.

The trends in HIV prevalence rates among high-risk groups in India seem to be comparable to trends previously observed in some African nations among prostitutes. This similarity suggests that the epidemic could spread to the general population to alarming levels, as happened in these countries, where the spread of HIV among the general population seems to have been preceded by a sharp increase in HIV prevalence among high-risk groups.

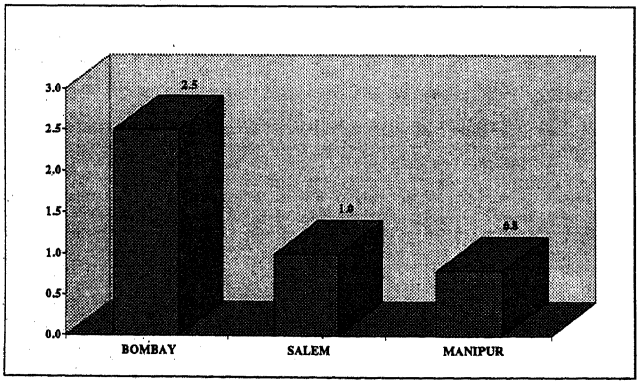

Figure 2. HIV positivity among pregnant women (1st round-sentinel surveillance.

Clearly, HIV infection is not restricted to such marginalized groups as prostitutes and drug addicts, but is spreading to more areas and to the general population in those areas through heterosexual transmission. Nevertheless, not all regions are being affected to the same extent. The apparent geographical clustering at this stage of the epidemic may be caused by differences in the proportion of the population engaging in high-risk behaviour or by unevenness in the surveillance system. Whatever the local pattern, however, the surveillance data taken as a whole demand that there be implementation of a comprehensive AIDS control programme as soon as possible.

Other issues

In India the prevalence of tuberculosis infection is 40% as evinced by tuberculosis testing. Of reported AIDS cases, 56% had tuberculosis of one or more organs. Thus, given this high prevalence of tuberculosis among those with AIDS, India is going to face the added problem of an increase in cases of tuberculosis even among those not suffering from AIDS.

Conclusion

Poverty and underdevelopment are key factors that contribute to the AIDS pandemic: financial difficulties and economic problems force men to leave their families to find work, encourage drug use and make prostitution a survival strategy[6]. If we take these factors into account, India has great reason to be alarmed. India recognizes this threat clearly. Accordingly, India has launched a comprehensive, nationwide AIDS control programme since 1992 with financial assistance from the World Bank and technical input from the World Health Organization. This programme consists of different components, namely: surveillance for HIV/AIDS; control of sexually transmitted diseases; condom distribution programmes; and information, education and communication designed to generate awareness of the disease and encourage change in risky behaviours. Further, the programme aims at providing comprehensive, nonstigmatizing care to all those who are already suffering from AIDS.

The HIV and AIDS epidemic in the Western Pacific

Rabin M. Sarda and George Petersen*

WHO, United Nations Avenue, PO Box 2932, 1099 Manila, Philippines
*WHO, House 120, Street 228, Sankat Chadomuk, Khan Mon District, Phnom Penh. Cambodia

THE Western Pacific Region of the World Health Organization (WHO) consists of 35 countries and areas, with a total estimated population in 1992 of 1535 million[1]. Seven countries account for 96% of this total. The region includes industrial countries, newly industrializing countries or areas, developing countries or areas, and some of the world's least developed countries. The regional population is expected to grow to 1700 million by the year 2000. The average national growth rate was 2% per year during 1985–90.

Global trends

A cumulative total 1,025,073 AIDS cases had been reported[2] worldwide up to the end of 1994. WHO estimated that the actual figure was closer to 4.5 million cases. Of the reported cases, the vast majority have been from the Americas and Africa, with Asia and the Pacific accounting for less than 2% of the total.

WHO estimates indicate that up to the end of December 1994, more than 18 million people had been infected by HIV[2], with the majority of the new infections during that year occurring in Africa and Asia. By the year 2000, WHO predicts 30–40 million HIV infections worldwide, with 90% of them expected to occur in developing countries[3].

Current situation in the Western Pacific Region

Available evidence suggests that the HIV epidemic in the Western Pacific Region is at a relatively early state compared to other parts of the world[4]. Few countries in the region had reported significant numbers of AIDS cases or HIV diagnoses prior to 1987. Since then, the epidemic has gradually spread throughout the region. Only eight of the thirty-five countries and areas (predominantly the smaller Pacific island nations) have yet to report any case of AIDS or HIV infection.

As Table 1 shows, as of 1 February 1995, 7349 cases of AIDS had been reported[4] from countries in the region. Eighty-six per cent of AIDS cases have been reported from three countries: Australia, Japan and New Zealand, but this proportion is decreasing (Figure 1). Of the reported AIDS cases, the vast majority were men (94.1%) and less than 1% of the reported AIDS cases were children under 15 years of age[5].

A cumulative total of 39,386 HIV infections had been reported[6] in the Western Pacific Region as of 1 February 1995 (Table 1). Reported rates of HIV infection vary from 101 per 100,000 population in Australia and 64 per 100,000 in French Polynesia, to fewer than 9 per 100,000 reported in Hong Kong and 0.1 per 100,000 in China. Eighty-six per cent of infections in the region have occurred in men and 8% in women. The proportion of HIV infections among children remains small, less than 1% of the total.

New HIV infections in Australia have remained relatively constant in the past three years. In Japan, they seem to have peaked in 1992. In Malaysia, however, they have been increasing (Figure 2).

Reported cases of HIV infection or AIDS do not show the real prevalence of these conditions in any given population. For example, many who are infected with HIV

are detected through screening procedures such as one would have prior to donating blood. Blood donors, however, represent only a small fraction of the population[7]. One can assume that there are others who are infected but who do not belong to the blood donor population.

To plan, develop and implement programmes, knowledge of the actual magnitude of HIV infection is necessary. Some countries have made estimates. These are often based on the number of reported cases, observed HIV prevalence rates, and the assumed size of the populations at risk. Australia, for example, estimates an HIV prevalence of 20,000–25,000, which is quite close to the reported figure. The Philippines, however, estimate the number of HIV-infected people at 35,000–50,000 compared to a reported 557 HIV infections.

Most countries in the Western Pacific Region have few reported cases, which makes reliable national and regional estimates difficult. Keeping these provisos in mind, WHO estimates that between 50,000 and 100,000 people are already infected in the region.

HIV and AIDS transmission in countries of the Western Pacific Region

The HIV epidemic in the Western Pacific Region has been characterized by wide variations between countries in the predominant modes of transmission, reflecting their great social, cultural and economic diversity and the measures taken to control the spread of the virus. Figure 3 shows the distribution of transmission categories for AIDS cases and HIV infections. It is important to note that AIDS figures represent the status of HIV approximately 10 years before, so that differences in rates in the modes of transmission indicate shifts in the way HIV is spread from one period to another. Close to 68% of AIDS cases in this region have been acquired through homosexual or bisexual contact. Injecting drug use and heterosexual transmission were responsible for 8.5% and 8.3% of AIDS cases, respectively. Note the decreased proportion of HIV infection among homosexuals and bisexuals and the increased proportion among heterosexuals and injecting drug users. This indicates the greater recent importance of the latter two risk categories in the transmission of HIV.

Figure 4 shows that homosexual transmission remains an important mode of transmission in many countries, including Australia, French Polynesia, Hong Kong, and New Zealand. In Australia, however, the number of homosexual men diagnosed with HIV is gradually declining (Figure 5). Another important feature of the Australian epidemic has been the low proportion of HIV infections among injecting drug users, which may explain why Australia has not seen an epidemic among heterosexuals.

Although the HIV epidemic in Japan was initially confined to people who had received blood products or blood transfusions prior to the screening of blood for HIV, during the last few years heterosexual transmission has been increasing (Figure 6).

Heterosexual transmission of HIV is predominant in many Western Pacific countries (Figure 7). In the Philippines, more than 50% of the reported infections have been acquired by this mode of transmission. In the Republic of Korea, eight out of ten AIDS cases and almost 70% of HIV diagnoses have resulted from heterosexual contact. Cambodia, Lao People's Democratic Republic and Papua New Guinea show heterosexual transmission of HIV in almost all cases where exposure was known.

In a few countries the role of injecting drug use in the transmission of HIV is becoming increasingly prominent. In Malaysia, 79% of the reported HIV infections

were attributed to injecting drug use. This number has increased dramatically since 1989 (Figure 8). More recently, Viet Nam has reported increasing number of HIV infections, over 80% of which is attributed to injecting drug use. China has also reported a significant number of HIV-infected injecting drug users, who account for 69% of all HIV transmission.

HIV has recently spread in Cambodia, reporting significant numbers of HIV infections for the first time in 1992 and 1993. Although only 1 AIDS case has yet been reported in Cambodia, more than 600 people have been diagnosed with HIV infection.

Risk factors for HIV transmission in the Western Pacific Region

Monitoring HIV infection in high-risk groups such as prostitutes, people with sexually transmitted diseases, injecting drug users, and homosexual or bisexual men is an essential part of HIV surveillance programmes. However, the results have to be carefully interpreted as survey methods differ. Unlinked anonymous testing is the method recommended for seroprevalence surveys and sentinel surveillance. In practice, voluntary confidential testing, compulsory testing of blood donors, and in some cases mandatory testing, are also used. As the test methods are not always specified and selection bias cannot be excluded, the results reported should be taken only as indicative of the situation in the areas surveyed. For example, sentinel surveillance of HIV infection in sexually transmitted disease clinics in Australia[8–10] which involve relatively stable population sources, performed at regular intervals and using unlinked anonymous testing, will yield far more reliable data than the irregular surveillance of STD patients in Cambodia.

Prostitution

HIV has recently spread rapidly among prostitutes in countries such as Thailand and India, which are close to the Western Pacific Region. With the exception of Cambodia, available data indicate that the spread of HIV among prostitutes has not yet occurred to the same extent in the region, even though sex industries catering to both local and foreign clients are well established in many countries.

The highest prevalence of HIV among prostitutes to date has been found in Cambodia. In one area, Toul Kork, 18 of the 127 (13.2%) women tested were HIV-infected. In a coastal area in the South, an unrepresentative sample of over 200 subjects showed[11] a prevalence of 38%. In Malaysia HIV prevalence among prostitutes has increased gradually, from zero in 1988 to 1.3% in 1991. In the mid-1980s, the prevalence of HIV among prostitutes tested in the Philippines was between 1.0 and 2.5%. Recent surveys, however, in Baguio and Cebu in the Philippines found no infection among more than 800 prostitutes tested, although testing bias could not be excluded. More recently, a survey in Metro Manila suggests a prevalence of 0.1–1.0% in this population group[12].

In the Republic of Korea, 411,125 tests performed between 1985 and 1991 revealed only 11 positive cases. No infection has been documented recently among prostitutes in Australia, Japan or Singapore.

Injecting drug use

The problem of HIV transmission through injecting drug use is escalating in Malaysia, where prevalence among injecting drug users rose from 0.1% in 1988 to 6.9% in 1992. In Viet Nam in early 1993, 92 out of 1061 (8.7%) of injecting drug users were found to be infected, most of whom came from Ho Chi Minh City. This has since increased to a cumulative percentage of 81% of 1809 reported HIV infections as of 1 February 1995. In China, injecting drug users infected with HIV were concentrated in Yunnan Province. Recent data, however, have indicated infection in other provinces as well. In Australia, the prevalence of HIV among injecting drug users remains at less than 5%. This may be attributable to the extensive efforts made to educate and protect injecting drug users in Australia, particularly with needle and syringe exchange programmes.

Homosexual and bisexual activity

Surveys conducted among men who have sex with other men show a range of prevalence from a localized high of 30.3% in Sydney, Australia, to zero in the Philippines. Japan and Singapore show a prevalence of 2.0% and 3.6%, respectively. Although the situation has stabilized in countries like Australia and New Zealand, data are still lacking on this transmission category in such countries as Cambodia, China, the Lao People's Democratic Republic, Malaysia, the Republic of Korea and Viet Nam.

Use of blood products

Blood transfusion and the use of blood products for haemophiliacs account for 6.1% of HIV transmission in the Western Pacific Region. The majority of these cases have been reported by Australia and Japan and represent transmission prior to the introduction of screening of the blood supply in 1985.

Perinatal transmission

Surveys performed to date among pregnant women have found virtually no HIV infection. This may be the reason for the less than 60 reported HIV infections and nineteen AIDS cases transmitted from mother to child within the region.

Sexually transmitted diseases

Systematic surveillance among those suffering from sexually transmitted diseases has been carried out in Fiji, Hong Kong, Papua New Guinea and Singapore. These and other studies show low levels of infection. In Cambodia, however, a recent study found 4.2% of 72 patients were infected. For the remaining countries, the lack of data is a result of insufficient surveillance in this category.

Future trends

Any forecasts of the future magnitude of HIV infection in the Western Pacific Region are bound to include wide margins. This is because there are many determinants of the infection and their significance for the region has not been thoroughly assessed. Present estimates suggest a two- to four-fold increase in the prevalence of HIV infection for the Western Pacific Region by the year 2000. This would mean that 100,000 to 400,000 people would be infected. However, many factors unique to the region may affect these figures; for example, the high level of literacy in most countries in the region, the large numbers of people with access to radio and television, the wide circulation of newspapers, magazines and books, the well-developed health infrastructure, especially in respect of maternal and child health and family planning, and the relatively low prevalence of ulcerative sexually transmitted diseases may lead to a lower prevalence of HIV. However, other factors, such as proximity to areas of high prevalence of HIV infection and injecting drug use, large-scale migration, and complacency may have the opposite effect. These factors will vary in importance in different countries. An essential part of HIV surveillance and prevention programmes is to single out the risk factors for spread and to implement locally appropriate strategies.

Heterosexual risk behaviour in Asia: The implications for HIV/AIDS

Tim Brown and Werasit Sittitrai*

Program on Population, East West Center, Honolulu, Hawaii
*Thai Red Cross Society Program on AIDS, 1871 Rama IV Road, Bangkok 10330, Thailand

IN the early 1980s the belief that Asia might avoid a major HIV/AIDS epidemic was widespread. As the epidemic spread in the Western world and devastated Sub-Saharan Africa, Asia appeared strangely immune. By the end of 1987, Asian countries had reported only 252 AIDS cases to the World Health Organization[1], and when a case did appear in Asia, it was most often associated with Asian men who had sex with men who had sexual contact with foreigners or had travelled abroad or with haemophiliac's use of foreign blood products. Indigenous transmission in observed AIDS cases was rare.

To explain this low rate some speculated that Asians might have a natural resistance to HIV infection. Others said that traditional Asian morality and the value placed on families were protecting the continent from the epidemic. The region seemed to have little cause for concern, and most countries did not undertake any large-scale efforts to prevent or slow down the spread of HIV.

In early 1988, this belief in Asia's immunity to the AIDS epidemic was shaken as HIV prevalences in injecting drug users in Thailand increased rapidly from zero to 30% over an 8-month period[2]. At the same time, studies of female commercial sex workers in Bombay and Madras revealed[3] HIV infection levels of 5%. Prior to this time, some HIV testing had been done among populations vulnerable to HIV in Asian countries, including Thailand and India, but had rarely found infection levels exceeding 1% in any groups other than haemophiliacs and men having sex with men. During the next few years, both India and Thailand saw rates of HIV infection climb first in injecting drug users and commercial sex workers, then in male patients with sexually transmitted diseases (STDs), and finally in pregnant women. For example, by mid-1993 nationwide median HIV prevalences in STD patients and antenatal clinics in Thailand had grown to 8.0% and 1.4%, respectively[4]. In Bombay by 1993 STD clinics showed rates as high as 26% and rates among antenatal women were approaching 1% (ref. 3). Studies of risk factors done in India and Thailand found that most of the infections had been contracted through heterosexual intercourse. Although the rapid spread of HIV started among injecting drug users and commercial sex workers, by the early 1990s the epidemic had clearly established itself in the general population.

Because most other Asian countries have not conducted as extensive HIV testing as India and Thailand, their situation is more difficult to assess. In most countries of the region, the number of reported AIDS cases is small, as seen in Table 1, which shows the cumulative number of AIDS cases reported through the end of 1990 and through mid-1994. In many of the countries the HIV/AIDS epidemic has remained largely invisible, although the increasing AIDS numbers show that an epidemic is underway in most of them.

Several factors have contributed to this invisibility. The first is the nature of HIV itself. In the past many Asian countries have relied largely on reported AIDS cases for data, with only limited HIV testing. Because illness takes many years to develop, and the introduction of HIV in much of Asia occurred in the mid-1980s, case

Table 1. Number of AIDS cases reported to the World Health Organization by Asian countries through December 1990 and June 1994. Source: Global Programme on AIDS 1994

Country	December 1990	June 1994
Bangladesh	1	1
Bhutan	0	0
Cambodia	0	0
China	5	36
Democratic People's Republic of Korea	0	0
Hong Kong	27	99
India	52	713

Nepal	4	24
Philippines	37	136
Republic of Korea	7	19
Singapore	21	75
Sri Lanka	6	37
Thailand	69	5654
Vietnam	0	107

numbers remain low. In addition, reported numbers are lower than the actual number of cases because HIV disease manifests itself through other diseases, such as tuberculosis and pneumonia. As a consequence, AIDS is often misdiagnosed or goes unrecognized, especially when physicians are not expecting it. This, along with the social stigma of AIDS in most Asian societies, has resulted in underreporting of AIDS cases.

The second factor is the lack of extensive HIV surveillance systems similar to the sentinel seroprevalence system in Thailand[2]. Most countries have only recently begun to establish systematic prevalence testing on even a limited scale. Thus, the quality and quantity of the available HIV data are only now beginning to improve.

The third factor is the public reluctance in Asian societies to discuss or admit to the behaviours that transmit HIV: injecting drug use; homosexual intercourse; and extramarital or premarital commercial and casual sexual intercourse. In most Asian countries, the limited studies of injecting drug use, sexual partnering patterns and sexual practices have focused primarily on attitudes toward drug use and extramarital and premarital sex, not on actual behaviour. While the surveys generally find that publicly expressed attitudes toward sexual activities outside marriage are negative, men are often allowed great latitude to engage in them without sanctions. These negative attitudes and the public reluctance to discuss the issues give the false impression that the risk behaviours needed to sustain an epidemic do not exist in many Asian societies.

However, despite these limitations sufficient HIV and AIDS data do exist to reveal certain similarities and differences between Asian countries. For example, the rates of HIV spread within different countries vary significantly. Although the first AIDS cases appeared in both Thailand and the Philippines in 1984, by 1993 infection levels among commercial sex workers were much lower in the Philippines, 0.6%, compared to approximately 9% among Thai nonbrothel-based commercial sex workers[4,5]. Current data indicate that the rate of spread is quite high in some countries, for example, Cambodia, India, Myanmar and Thailand, but is substantially slower in others, such as China, Hong Kong, Japan, the Philippines and the Republic of Korea.

The relative importance of different transmission modes also varies substantially. In Japan, haemophilia patients who received blood products imported mostly from the United States account for 64% of all AIDS cases[6]. In China and Malaysia most AIDS cases cite injecting drugs as the route of exposure[7,8], but in Japan fewer than 1% of nonhaemophiliac AIDS cases are attributed to injecting drugs[5]. In Hong Kong, India, Indonesia, and Thailand most infections in reported AIDS cases have been through sexual intercourse[3,4,9,10]. However, in Hong Kong and Japan infection through homosexual intercourse is more common, while heterosexual intercourse is the more frequent transmission route in the other countries.

The HIV/AIDS epidemic in Asian countries is dynamic in nature, and the comparative contribution of the various transmission routes is changing with time. One striking similarity among the countries of Asia is that most are either seeing or moving toward predominantly heterosexual transmission of HIV. For example, in Hong Kong, while the overall ratio of homosexually transmitted to heterosexually transmitted HIV infections is 1.17 to 1.00, if one only considers those infected in 1993, the ratio is 1 to 2 in favour of heterosexual infections[9]. Japan has almost twice as many detected heterosexual HIV infections as homosexual infections, and new heterosexual AIDS cases have outnumbered homosexual AIDS cases since 1992 (ref. 6). In Singapore, a second wave of heterosexual infections is now following the initial wave of homosexual infections[11]. There is little doubt that in the long term the HIV/AIDS epidemic in Asia will be principally a heterosexual epidemic. Heterosexual risk behaviour is thus playing a key role in the epidemic.

The roles of commercial, casual and marital sex in the heterosexual epidemic

If the course and severity of the epidemic in Asia are to be anticipated and an understanding reached of the variation among countries, exploring the forms of heterosexual transmission and their relative contributions to the epidemic is important. Heterosexual transmission can occur in three settings: during commercial sex, during noncommercial casual sex outside marital relationships, and during marital coitus. Comparing the relative rates of transmission in these settings and examining the prevalence of each in Asian societies may help to clarify the situation. Before looking more closely at these factors, a brief examination of the Thai situation can provide valuable insights into the factors influencing a heterosexual epidemic.

The Thai HIV/AIDS epidemic has been one of the most intensively studied epidemics in history. Although the first Thai AIDS cases occurred in 1984, the epidemic did not begin to spread rapidly until late 1987 among injecting drug users. In 1989, comparatively early in the epidemic, Thailand established national surveillance for HIV that has allowed tracking of the epidemic's progress[12,13]. Based on these data, collected by the Ministry of Public Health and the Royal Thai Army, and on extensive epidemiological and behavioural studies, the patterns of the Thai epidemic are well understood. Five waves have been observed: (1) injecting drug users; (2) female commercial sex workers; (3) clients

of commercial sex workers; (4) wives and girlfriends of clients and (5) children born to infected mothers. (For more detailed material on the Thai epidemic, see refs. 2, 4).

Unlike HIV/AIDS epidemics in the West, where the contribution of heterosexual transmission has been low, the Thai epidemic has seen a rapid spread among heterosexuals, with infections among female commercial sex workers spreading particularly fast. For example, limited testing of sex workers in Chiangmai in northern Thailand in 1987 found no HIV, but by 1989 levels had surpassed 40% in brothel based sex workers[2]. This explosive growth in infection among brothel-based female commercial sex workers resulted both from the large numbers of clients they serviced and from the sex workers' high levels of other STDs, which enhance HIV transmission. At the same time, infection levels among indirect sex workers, working out of bars, nightclubs and restaurants grew more slowly because both their client numbers and STD levels were lower. For example, in mid-1990, when HIV prevalence among brothel-based sex workers was 14% nationwide, it was less than 3% among indirect sex workers.

Despite the rapid growth in infection among sex workers, the bulk of the country's present HIV infections resulted from the third and fourth waves: clients of sex workers and their female sexual partners. In 1990, the Survey of Partner Relations found that 23.4% of Thai men between 15 and 49 years of age had engaged in commercial sex in the last year[14]. This large pool of susceptible males, in conjunction with high rates of female sex worker to client transmission[15], contributed to a rapid rise in new male infections between 1989 and 1991 (ref. 16). The rate of new male infections has now slowed substantially because of an aggressive national program that has increased condom use, brought about a substantial drop in STD levels, and reduced the number of men visiting sex workers, but the third wave has left behind close to half a million infected males.

The fourth wave, wives and girlfriends of clients of commercial sex workers, proceeds at a slower but relentless pace. Recently completed studies have found that transmission from infected husband to wife occurs at a much lower rate than from sex workers to clients[17]. This probably results because rates of STD co-infection are lower in both marital and noncommercial casual sexual contacts than in commercial contacts. However, because married couples and noncommercial sexual partners rarely use condoms in Thailand, in the absence of intervention most infected men will eventually infect their wives or girlfriends, although it may take several years. Thus, female infections, which currently number about one quarter of a million, lag substantially behind male infections. This is in contrast to the situation in Africa, where male and female infection levels are roughly equal, and reflects the important role played by commercial sex in the early dynamics of the Thai epidemic. The extent to which unmarried Thai women are at risk depends largely on how males' sexual networks link casual and commercial sex. Because women married to infected men outnumber sex workers, most infected women in Thailand contracted their infections from their husbands, despite the higher HIV transmission rates in commercial sex.

Other countries can learn several important lessons from the Thai experience. If a country has a sex worker population with high client numbers and STD levels, then the growth of HIV can be explosive. Given that HIV had been introduced to Thailand as early as 1984, but that infections among commercial sex workers were rarely found until 1988, this indicates that a substantial delay can occur between HIV introduction and the beginning of this explosive growth. The absence of detected HIV infections in commercial sex worker populations today should not be misconstrued as the absence of potential for a rapid spread of HIV. The much lower seroprevalence among indirect workers compared to brothel-based workers shows that the frequency with which commercial sex workers have clients has a significant effect on the rate of infection on a national scale. Thus, the relative mix of brothel-based commercial sex with other forms of commercial sex may provide some indication of the overall vulnerability to the rapid spread of HIV. Finally, the rate of HIV transmission in commercial contacts and in marital or noncommercial casual contacts can vary greatly, perhaps by an order of magnitude or more. Thus, the heterosexual epidemic may proceed much more slowly in countries where noncommercial casual sex is more common than commercial sex.

As noted earlier, the predominantly heterosexual nature of the AIDS epidemic is becoming apparent in most Asian countries. Based on the analysis of the Thai epidemic presented here, the rate of growth and ultimate magnitude of the HIV/AIDS epidemic in each Asian country will be determined largely by: the prevalence of heterosexual commercial sex; the overlap between commercial, casual and marital sex; and the levels of other sexually transmitted diseases. To assess whether a particular country or population is likely to face major HIV problems, these are the factors that must be examined. The remainder of this paper will, therefore, focus on the levels of heterosexual risk in the countries of Asia to assess the potential for the spread of HIV in the region as a whole.

Heterosexual risk behaviour in Asia – commercial sex

As India's and Thailand's experiences have shown, commercial sex can play a critical role in HIV transmission in Asia. While commercial sex is certainly not unique to Asia, it may have more of a role in epidemics in the region than in other parts of the world.

Commercial sex, despite frequent public condemnation, has a long history of tacit acceptance in many Asian societies. As a consequence, it is widespread, and sex workers often have large numbers of clients. For the human immunodeficiency virus, these high client numbers offer two obvious advantages: (1) commercial sex workers have higher than normal rates of infection and reinfection with other sexually transmitted diseases, which enhance HIV transmission; and (2) the larger numbers of sexual partners offer increased opportunities for the virus to spread from client to sex worker and from sex worker to client. These factors have driven the rapid growth of HIV seen in Cambodia, India, Myanmar and Thailand.

Efforts at HIV prevention during commercial sex are often hampered by the comparative lack of control sex workers have over sexual transactions in Asian societies, where control usually rests with the client. Thus, even if a sex worker wants to take precautions against disease transmission, for example, by using condoms, this is not her choice to make. This lack of control greatly increases the workers' vulnerability to HIV and other STDs.

The roots of commercial sex in Asia are both cultural and economic. Culturally, widespread gender inequality in sexual matters is the most important factor contributing to the demand for commercial sexual services. Many Asian societies have very different expectations from men and women in terms of sexual behaviour. Women are almost universally expected to be virgins at marriage and not to engage in extramarital sexual activities. For men, by contrast, despite publicly expressed attitudes opposing premarital and extramarital sex, strong societal sanctions against such practices are lacking and in some places men are expected to be sexually experienced at the time of marriage or people believe that men need sexual variety. This creates an imbalance between male sexual demand and female sexual supply. While many men seek sexual contact outside of marriage, either premaritally or extramaritally, few women are available. This creates the high demand for female commercial sexual services.

Growing economic prosperity and economic disparity between urban and rural areas are also fuelling the growth of commercial sex in the region. While the countries of Asia as a whole are experiencing phenomenal economic growth, the resulting benefits are not equally distributed between urban and rural areas. While improving economic conditions drive an increasing consumerism, permeating the rural villages, where most Asians live, the resulting employment opportunities are generally concentrated in urban areas. This increases the urban/rural economic disparity, leaving villagers without the means to pay for either the basic necessities of life or for the consumer items and luxuries that are becoming national norms. Lacking the education or training necessary for many of the newly created jobs, many young female villagers turn to commercial sex as an alternative for supporting their families. The steady flow of men and women into urban areas for work also removes them from their traditional social environments and disrupts social norms, thereby further increasing the demand for and acceptability of commercial sex.

Economic disparity is growing not only between urban and rural areas, but also between countries in the region. This has fuelled an active international sex trade encompassing both sexual tourism and commerce in female sex workers. Men visiting commercial sex workers while travelling is commonly reported throughout Asia (see, for example, ref. 18 on Japanese men in Thailand and ref. 19 on Korean men). As education, improving economic conditions, and the fear of HIV reduce the supply of sex workers in Thailand, the deficit has been made up by sex workers with lower education levels and less knowledge of the AIDS epidemic imported from Myanmar and China. This is a regionwide phenomenon: Nepalese sex workers often go to India for work, Vietnamese sex workers are frequently found in Cambodia, and Thai sex workers are regularly imported into Japan. Should any of these women test positive for HIV during their foreign employment, they are inevitably returned to their country of origin. As a consequence, many of the earliest female AIDS cases in Asia are women who formerly worked for commercial sex in other countries and may have contracted HIV there.

The tacit acceptance of commercial sex and the high male sexual demand, combined with poverty and increasing consumerism, make commercial sex work an economically attractive alternative for women, especially those with little education or from poor families, and the supply/demand imbalance guarantees that female commercial sex workers will have a steady flow of clients, making it a viable profession.

The quiet acceptance of commercial sex is fostered by strong historical traditions in many Asian cultures. In a number of countries, laws against commercial sex are historically recent. Given the time often needed to effect changes in cultural beliefs and attitudes, in many countries the legal sanctions against commercial sex may be in direct conflict with an underlying cultural acceptance of the practice, resulting in lax enforcement of these laws. For example, China has a long history of both government and privately run commercial sex, perhaps starting as early as the seventh century BC[20]. It was only when the communists came to power in 1949 that commercial sex was made illegal. Despite legal restrictions, the recent rapid economic expansion, especially in southern China, has fuelled the growth of commercial sex and arrests of sex workers and clients have been increasing. In the Ayuddhya period in Thailand (1350–1767), commercial sex was both legal

and subject to government tax, becoming illegal only in the 1950s (ref. 21). In India, the Hindu tradition of dedicating girls (*Devadasi*) to gods and goddesses lowered the stigma against these women engaging in commercial sex work and provided a cultural basis for accepting commercial sex[22–24].

The result of these cultural, traditional and economic factors is that every country in Asia has a commercial sex industry, although in most places it is technically illegal. Because the number of clients is high and drawn from all strata of society, commercial sex occurs in a number of settings and forms to cater to the diversity and economic resources of the clientele: brothels, tea houses, coffee shops, street walkers, barber shops, massage parlours, and so on. The relative mix of these settings varies substantially from country to country. In most countries, the extent of the sexual service industry has been poorly determined, largely because of its illegality and the resulting invisibility of the sites, public reluctance to discuss the issue openly, and the protection afforded from official scrutiny by its economic profitability. While investigators have conducted numerous studies of commercial sex workers in Asia, these have focused primarily on the women's health and working conditions and very few have examined the total number of sex workers or establishments. Similarly, studies exploring the extent and practices of men who visit commercial sex workers are a recent development, prompted largely by the HIV/AIDS epidemic. Many of these studies, for example, in Malaysia, the Philippines, Singapore and Thailand were part of the effort by the World Health Organization's Global Programme on AIDS to encourage and support studies of sexual risk behaviour worldwide[25]. In several cases, these studies have proven extremely valuable in making policy-makers aware of the potential problems their countries face.

While current data on clients are limited and not always strictly comparable because of variations in sampling, population subgroup, underreporting differences, and information gathered, the highest rates of commercial sex have been reported in southeast Asian countries and the lowest in east Asian countries. Nevertheless in each country that has examined the situation, the fraction of the total male population visiting sex workers is not insubstantial, thereby creating the potential for rapid spread of HIV. For example, in Thailand in 1990 the Survey of Partner Relations found that 23.4% of males had visited a sex worker within the last 12 months[14]. This number had dropped to 10.1% by 1993. In Phnom Penh, Cambodia, a survey in 1993 found that 41% of sexually experienced males had visited a sex worker within the last year[26]. A survey in Manipur state, India, found that 19.1% of married men had visited a commercial sex worker in their lifetimes[27]. East Asian numbers appear somewhat lower, but researchers suspect underreporting. For example, in a survey conducted by the Hong Kong AIDS Foundation in 1992, 5.5% of male respondents had visited sex workers in the last 12 months[28]. An earlier survey in Hong Kong had found that 22% of males had visited a sex worker by age 26 (ref. 29). Similar numbers have been noted in Singapore. In a sample of international travellers in Korea, 24% reported having paid for sex in the last 5 years[19].

Heterosexual risk behaviour in Asia – non-commercial casual sex – premarital and extramarital sex

Needle sharing and commercial sex have often provided the initial high-grade fuel for Asian HIV/AIDS epidemics, resulting in infection of a large fraction of injecting drug users, female commercial sex workers, and clients of sex workers. From the clients HIV spreads to their girlfriends and wives. Unless condom use among married couples is common as a contraceptive, husbands who are infected through commercial sex will almost invariably transmit the infection to their wives. These women are at high risk even though they are engaged in 'low-risk' behaviour, thereby illustrating the danger of not considering the risk of all potential avenues of heterosexual HIV transmission. Thus, assuming that all infected males eventually marry, the size of the female population at high risk of HIV infection is the same as the population of male clients. If one includes extramarital and premarital sexual contacts, and the possibility that males may have multiple female partners over a period of time, the female population at risk becomes larger than the male population at risk.

While comparatively few studies have looked at sexual networks in the region, many have inquired about levels of extramarital and premarital sex. The findings raise serious concerns throughout Asia. In general, the studies confirm the difference in levels of male and female extramarital and premarital sex. In Japan, for example, a 1990 survey found that 19% of urban married males reported extramarital intercourse in the last 12 months compared to only 8% of women[30]. A study in Eastern Shan State in Myanmar found that 40.3% of married men, but only 5.5% of married women, reported extramarital intercourse during their lifetime[31]. In Manipur state, India, 27.8% of unmarried men and 11.3% of unmarried women reported having had intercourse[27]. In Nepal 24.1% of males and 14.9% of females reported premarital sex. The investigators observed a strong association of seasonal migration with premarital and extramarital sex in this case[32,33]. Similar high levels of extramarital and premarital sex have been found in many other countries, even when gender differences are not reported. For example, in Malaysia 33% of sexually experienced men and 11% of married men reported casual sexual contacts in the last year[8]. In

Korea, 46% of males who travelled internationally reported extramarital sex in the last 5 years[19].

There are some indications that male and female behaviour may be changing among adolescents in some parts of Asia, with closer equality of male and female premarital sex. For example, in a survey of final-year Japanese high school students, 20.5% of males and 22.9% of females reported sexual experience[34]. A similar study of students in Hong Kong found that 21% of males and 19% of females reported sexual experience[35]. How this translates into changes in partnering patterns and the relative mix of commercial and casual sex is not known.

The final factor that will influence the growth of the heterosexual epidemic is the linkage between commercial and casual sex. Studies of sexual networks in Thailand have found that most of the men visiting commercial sex workers often have one or more girlfriends prior to marriage, which may place their casual partners at risk[36,37]. Studies in Hong Kong and Singapore, in contrast, have shown less overlap between commercial and casual sexual relations, with most males having primarily commercial or casual contacts, but usually not both, prior to marriage. The total risk to women having casual sex with clients of sex workers may thus vary greatly from country to country. However, it should be remembered that HIV risk in a sexual network is not confined to simultaneous overlap of casual and commercial partners but is cumulative. If a single man engages in commercial sex while young and becomes infected, then all subsequent partners, including his future wife, are at risk.

Implications for the HIV/AIDS epidemic

Although most Asian countries report low numbers of AIDS cases and detected HIV infections, the trend is clear: heterosexual sex is becoming the dominant contributor to the growth of the HIV/AIDS epidemic in Asia. What does this mean for the future progression of the Asian epidemic, for intervention, and for future research needs?

Despite the limited availability of behavioural and epidemiological data, an explanation of the variation between countries is possible. Those countries seeing a rapid spread of HIV, for example, Cambodia, India and Thailand, are countries where commercial sex is common and a large percentage of the male population are clients of commercial sex workers. The resulting large number of nightly clients for commercial sex workers combines with elevated levels of other STDs to produce extremely high HIV transmission rates. The result is the frighteningly rapid growth of the epidemic. Those countries with lower rates of growth, for example, Hong Kong, Japan and the Philippines, are those where casual sex is as common or more common than commercial sex (but where commercial sex services still exist, although to a lesser extent) with lower overall levels of heterosexual risk. The epidemic has spread more gradually in these countries, but even within these countries, commercial sex presents greater risk for contracting HIV, and most early male heterosexual AIDS cases are associated with it. Thus, heterosexual risk in commercial settings is becoming the dominant factor in reported AIDS cases.

Casual sex has played less of a role in Asian AIDS epidemics, both because it occurs less often than in the West or in Africa, and because the transmission rates associated with it are lower. The female/male imbalance in sexual activity in Asia has slowed the spread into the unmarried female population. This is not to say that interventions can ignore casual sex, especially in the light of recent trends toward increasing casual sexual activity among females of the younger generation at precisely those ages where most sexually transmitted diseases, including HIV, are concentrated. Casual sex also deserves serious attention because the low perception of associated HIV risk leads to low levels of condom use. Even in countries such as Thailand, where condom use in commercial sex has risen dramatically, it remains quite low in casual sex, despite a large reservoir of currently infected males.

However, while most male infections in Asia over the next several years will occur in commercial settings, most female infections will happen in marital settings. Because comparatively few Asian females engage in casual sexual contacts, most of their HIV risk accrues from the sexual practices, current or past, of their mates. These cases will grow more slowly because of low HIV transmission rates in the absence of STDs, but they will grow inexorably unless interventions can be developed to address the risk posed to Asian women by their spouses' premarital and extramarital sexual activities.

Although existing behavioural data are limited and much research remains to be done, some subregional patterns are becoming apparent. Most countries of southeast Asia share a common pattern of tolerance toward commercial sex and frequent use of commercial sex services by males. This leaves these areas vulnerable to the same explosive growth seen in Thailand, and indeed, this is now being seen in Cambodia, Myanmar, and perhaps Vietnam. In east Asia, data are more limited, but studies indicate that commercial and casual sex occur at lower levels than in southeast Asia, with less overlap between casual and commercial sex. Nonetheless, a substantial portion of the male population has made use of commercial sex services in their lifetimes. These countries still have large enough populations of clients for the heterosexual epidemic to grow quite large. It will just take more time to get there. South Asia is somewhat of an enigma with fewer behavioural studies done, as well as substantial

variations in behaviour and practices even within countries, for example, in India. This has resulted in geographically uneven growth of the epidemic in India and makes assessing the country as a whole more difficult. No behavioural risk or epidemiological data are available for countries such as Bangladesh and Pakistan. However, the absence of data does not imply an absence of risk, and the case of India shows the potential for HIV spread in the south Asia subregion.

The heterosexual nature of the AIDS epidemic in Asia has consequences for the ultimate size of Asian epidemics. In one sense, epidemics in men having sex with men and in injecting drug users are self-limiting, because they constitute a comparatively small fraction of the total population. For example, in most places injecting drug users make up less than 1% of the total population and men having sex with men may represent 2–3%. Heterosexuals, however, make up the bulk of any population; thus, the group of susceptible people is much larger. The risk for individuals is also raised depending upon their age. For example, while in Hong Kong and the Philippines only a few per cent of males visit commercial sex workers, these men are concentrated in the 15–30 age range, meaning that the risk for individuals in this age range is substantially elevated.

This analysis has several implications for intervention programmes. Urgent intervention to reduce HIV transmission in commercial sex is essential. The national programme in Thailand has demonstrated that condom promotion, aggressive STD control, and mass media campaigns can radically reduce the rates of disease transmission in commercial sex[38]. These efforts have succeeded largely because authorities worked with brothel owners and sex workers to increase condom use and improve STD treatment, while simultaneously using mass media and workplace interventions to reach clients, rather than attempting to eliminate commercial sex. Given the cultural and economic forces sustaining the commercial sex industry, eradication in the short term is an idealistic, not a realistic, option. If one merely removes the supply of sexual services without altering the demand, the demand will express itself elsewhere. Commercial sex will be driven underground and intervention will become impossible. Such efforts will have the net result of promoting the spread of HIV. For now, it is better to focus on decreasing the HIV risk associated with commercial sexual contact through condom promotion and STD control.

From both the public health and human rights viewpoints there are clear reasons to discourage commercial sex, but this is a long-term, not a short-term strategy. Efforts should begin now to change the norms and practices of young people regarding commercial sex before their sexual habits have formed. Mass media approaches can be used to reach the public and show the negative aspects and risks associated with commercial sex. However, such efforts must be handled with care so as not to stigmatize further sex workers. Other long-term approaches include working on the roots of the commercial sex industry: poverty and social displacement. Development policies can increase employment and educational opportunities for young women, especially in rural areas, so they have fewer incentives to engage in commercial sex work. This might be done by providing scholarships for young, rural women to allow them to continue their education beyond primary school. In developing new industrial zones, consideration should be given to moving entire families rather than asking husbands to leave their wives and children behind when they leave to find work. This will help by providing a more normal social environment, thereby reducing the demand for sexual services. Finally, efforts to improve women's status and their control in sexual situations should continue, because the roots of Asia's HIV problem lie in the inequality between the genders.

Intervention in the casual and marital sex arenas are also needed. At present condom use in casual sexual contacts is almost nonexistent in most of Asia. As the heterosexual spread of HIV infection continues, this places large numbers of people at risk for contracting HIV. Focusing on this is particularly important in countries with strong sexual network linkages between casual and commercial sex, for example, in southeast Asia. General efforts to educate the public should stress that all vaginal sex carries a risk of HIV transmission, focusing on the act rather than on the partner. Too often in the past the emphasis has been on commercial sex in education messages, not on vaginal transmission, leaving many with the impression that it was who you had as a partner, not what you did, that placed you at risk. Education efforts should teach proper use of condoms and negotiating skills for sexual situations. Another essential component of programmes to address casual sex should be the reduction of barriers to access to condoms and STD treatment for single men and women. In many places, for example, Indonesia[39], unmarried people face significant social and structural barriers to condom access or STD treatment.

For women in Asia, the greatest risk of HIV comes from regular sexual partners, primarily husbands. In marital settings, approaches to increase sexual communication between husbands and wives should be explored. Married Asian women need to understand the risks they face. This will only happen if husband and wife discuss sexual matters and come to a mutual understanding. Part of these efforts will involve education to make women aware of the levels of premarital and extramarital activity in their countries, and part will be training in skills and building mechanisms of peer support so that women are in a

position to influence their husbands' behaviour. In addition, governments could consider promoting voluntary premarital or pre-pregnancy testing and counselling. If properly executed, such efforts might encourage men to reduce their premarital and extramarital risks, while providing women with the knowledge they need to protect themselves.

Finally, an examination of the existing situation emphasizes the need for expanding knowledge about sexual risk in Asian countries. While studies have been done in many countries, they are of varying quality and generalizability. Only a handful are scientifically executed nationwide samples that can be said to represent adequately the behaviours in the country. In many cases, studies have been weakened by high levels of nonresponse. In most Asian countries, little or no information is available on sexual behaviour in rural areas, where most people live. In other countries no representative sexual behaviour studies have been done at all. If national policies are to be based on a realistic appraisal of the level of HIV risk in a country, and if the effectiveness of intervention programmes is to be evaluated, regular, consistent and methodologically sound surveys need to be conducted at regular intervals. Given the importance of commercial sex in the Asian HIV/AIDS epidemics, such studies should explicitly gather information on both casual and commercial sex. Behavioural surveillance should be an essential component of every national AIDS programme, with national surveys executed every 2 or 3 years to track trends and changes. Two such studies done 3 years apart in Thailand found substantial increases in condom use along with a significant decline in visits to commercial sex workers, which indicates that the national programme is achieving its goals. Such regular behavioural surveillance should be coupled with intensive qualitative and quantitative studies of the forms and prevalence of commercial sex and the levels of HIV and STD among commercial sex workers.

A common misconception has been that because most countries in Asia have seen fewer AIDS cases than Thailand, they do not have sufficient levels of risk behaviour to support a widespread, heterosexual HIV epidemic. Recent shifts in epidemiological patterns and behavioural studies done in the region have shown this to be untrue. While the epidemic will vary in terms of its growth rate and ultimate size in different countries of the region, each of them has sufficient heterosexual risk behaviour to support a large-scale HIV/AIDS epidemic. Just because they have not experienced a large epidemic by 1994 does not mean that they are immune to one in the future, but it does present them with a unique opportunity to intervene early and prevent much death and suffering. An immediate investment in national programmes to reduce risk in commercial settings coupled with a strong education programme aimed at the general population will reap immense benefits in averted costs and social destruction. Immediate action is essential. Every month of delay only adds to the epidemic's eventual social and economic cost.

The economics of the AIDS epidemic: Lessons from the United States

Sherry Glied

Columbia School of Public Health and Department of Economics, Columbia University, 600 West, 168 Street, New York, NY 10027, USA

THE AIDS epidemic officially began in 1981, when a number of physicians in New York and California described the existence of a terrible new disease that was afflicting some of their homosexual patients[1,2]. Later epidemiological research documented cases of infection by the human immunodeficiency virus that had occurred in the United States before 1981 and in countries other than the United States[3]. Today, HIV infection has spread around the globe. Nonetheless, in the thirteen years since those New York and California cases, more AIDS cases have been diagnosed and officially reported in the United States than in any other country. The AIDS cases reported in the United States through 1992 accounted for 44% of all documented AIDS cases for that year[4]. Estimates of the number of AIDS cases in Africa far exceed the US figures, but many of these cases are not reported[3].

Together with the large number of cases diagnosed, the research funding capacity of the United States government and the encouragement of vocal groups of people with AIDS have made the United States the predominant setting for AIDS-related research. In 1990 alone, the United States federal government spent more than $1.6 billion dollars for AIDS-related research and control activities, including substantial funding for social and behavioural research[3]. More than 500 articles have been published on economic, historical and ethnographic aspects of the epidemic in the United States.

The course of HIV disease varies little, whether a case is diagnosed in the United States or in a developing country[5]. As a consequence, medical researchers around the world have been able to benefit from US investments in AIDS research. More than most other diseases, AIDS raises complex issues that cut across economics, sociology, organizational behaviour, and psychology as well as medicine. The nature of HIV transmission, the long incubation period of the virus, and the devastating impact of the illness strongly suggest that economic and other social science research is critical to understanding and ultimately conquering this disease. While at first glance the disease's economic and social implications appear to be quite different in developing and industrial countries, some of the results of the many social science research projects in the United States are relevant for Asia too. This paper describes twelve lessons learnt from such research.

Estimates of the cost of treating HIV infection should incorporate both AIDS and pre-AIDS costs

Before 1993, the clinical definition of AIDS in the United States included only those with specific symptoms of the disease. In 1993 the surveillance definition was broadened to include those with severely depressed immune systems whether or not they manifested particular symptoms[6]. Under the new Centers for Disease Control definition of AIDS, patients' HIV status and CD4 counts (a measure of immune status) alone may determine a diagnosis of AIDS. This adjustment in the surveillance definition has had a substantial impact on the number of cases reported. In New York City, for example, researchers expect a 50% increase in cases among injecting drug users because of the change in definition[7]. Outside the United States, the costs of testing for serostatus and CD4 counts may limit the effect of any broadening of the case definition, leaving many HIV-infected people with severe immunosuppression outside the official count of AIDS cases.

The US experience suggests that estimates of the cost of treating HIV infection that use earlier definitions and begin counting costs only after AIDS symptoms begin may significantly underestimate the full medical costs of the disease. Based on the pre-1993 definition, an estimated 30% of the total HIV-related costs in the United States were for HIV-infected patients who did not have symptoms of AIDS[8]. US estimates suggest that the annual costs of treating HIV infection prior to the development of AIDS symptoms are between 10 and 25% as high as the cost of treating AIDS[9, 10] and that 40% of the lifetime per person cost of HIV infection is incurred before the development of AIDS[11]. Estimates of the proportion of total costs incurred in treating presymptomatic HIV infection in the United States may exceed comparable estimates for other countries because a portion of the US cost of treating presymptomatic patients covers costly prophylactic drug therapies. Estimates that predate the widespread use of such therapies, however, also describe significant costs incurred prior to AIDS diagnosis for patients with wasting syndrome, lymphadenopathy, and other pre-AIDS consequences of HIV infection[12,13].

These studies suggest that financial estimates of the effect of HIV on the health sector should move beyond measuring the costs of AIDS alone. Especially in areas where HIV testing is not done routinely, health care costs may rise substantially before large numbers of AIDS cases have been diagnosed and before the spread of the epidemic is recognized.

Estimates of the cost of the HIV epidemic should incorporate estimates of the cost of related opportunistic infections

The HIV epidemic in the United States has been associated with a resurgence of other infections, particularly tuberculosis[14, 15]. Tuberculosis, an airborne disease, is far more infectious than HIV[3]. HIV-infected patients, with their depressed immune systems, are especially vulnerable to tuberculosis. As the number of HIV-infected people with tuberculosis increases, others, even those who are not HIV-infected, run a greater risk of encountering tuberculosis carriers and becoming infected.

Tuberculosis is a costly disease. For those with non-drug-resistant strains, the estimated cost (inflated using the medical care component of the US consumer price index) of hospital care in the United States averaged $9000 (in 1991 dollars) in one 1980 study[16]. Higher rates of infection, especially in populations that may not complete the course of drug treatment, raise the spectre of drug-resistant tuberculosis. Drug-resistant strains are far more difficult and costly to treat successfully. In the United States the cost of treating drug-resistant tuberculosis can reach as much as $200,000 per case[17].

Tuberculosis was almost eradicated in the United States before the beginning of the HIV epidemic[17]. The dramatic recent growth in cases, especially in centres of HIV infection, raises the possibility that the HIV epidemic may ignite additional subepidemics of costly infectious diseases. If HIV sets back progress in the control of other infectious diseases, the total costs associated with the virus may dwarf those that economists have computed until now.

Health planning, particularly the development of alternative care facilities, can substantially reduce the cost of AIDS care

The earliest estimates of the costs of HIV infection in the United States documented an enormous disparity between costs in the two major centres of infection, New York and San Francisco[18]. Costs of treatment in New York were almost twice as high as costs in San Francisco. This difference has persisted over time and cannot be attributed to differences in the characteristics of AIDS patients in the two cities. Rather, the variation stems from the alternative treatment patterns employed in San Francisco and New York[19].

The less costly pattern of treatment in San Francisco arose because local homosexual men's groups rapidly organized outpatient treatment and hospice facilities for people with AIDS[20]. By contrast, few such community-based out-of-hospital facilities were available in New York[21]. The presence of community-based facilities in San Francisco enabled doctors and hospitals to establish patterns of care that relied on outpatient and nonhospital therapy[22–24]. Despite efforts to establish alternative forms of care for people with AIDS in New York, patients in New York still spend substantially longer time in hospital than do those in San Francisco and are much more likely to die in hospital[19, 25].

Even within cities, patients who have access to out-of-hospital facilities incur lower costs than those who do not. Within New York, the costs of care for injecting drug users without stable housing are significantly greater than those for similar patients with stable housing facilities[26]. The role of social support in reducing costs is particularly evident in the case of paediatric HIV infection. Mothers infected with HIV may not be able to care for their HIV-infected babies and may leave them in the hospital. The length of stay in the hospital for these babies may be as much as four times as long as for babies born with HIV infection who have homes[27].

In response to the growing number of HIV-infected babies in US hospitals, health planners and community groups have developed special foster care facilities[28, 29] for HIV-infected babies. Like the alternative treatment and care facilities developed for adults in San Francisco, these foster care facilities for babies have the potential of reducing the cost of care for HIV patients without diminishing the quality of care provided. These innovations highlight the importance of health planning and interorganizational coordination in developing cost-effective forms of care for people with AIDS.

The cost of AIDS control should be incorporated into estimates of the economic effect of the epidemic

The costs of treating AIDS are so high that investments in prevention and control will frequently be cost-beneficial. The costs of these investments, however, are real resource costs associated with the epidemic. In the United States, these costs include the cost of AIDS research, which in 1991 came to $805 million at the National Institutes of Health alone[30], the costs of tracking the disease, which in 1991 came to $509 million for the Centers for Disease Control[3], the costs of educational campaigns, which in 1991 totalled $700 million for federal and state educational programmes[31], and the cost of precautions to avoid HIV infection. In

health care settings, the cost of implementing the precautions recommended by the federal government amount to more than $800 million per year[31].

These budget items by no means exhaust the range of national efforts for AIDS prevention and control, but these alone, taken together, cost about as much as the lifetime cost of treating 23,000 HIV-infected people[11]. Exclusion of the costs of prevention and control from estimates of the cost of the epidemic leads to significant understatement of its economic impact.

Concentrating AIDS care in a few centres may improve quality and reduce cost

A series of recent studies in the United States have examined the relationship between hospitals' experience in treating HIV patients and the quality of outcomes achieved. In keeping with results from studies of other diseases, researchers have found that hospitals with more experience in treating AIDS generally achieve better results[32]. Mortality rates for patients with a variety of AIDS-related opportunistic infections are significantly lower in hospitals that have treated many AIDS patients[33, 34]. While these studies do not measure the cost of care, other studies have examined changes in the cost of care over the course of the epidemic. These studies suggest that as health providers and health systems learn about HIV the cost of treatment declines. In particular, over a period of time, providers are more likely to have access to and to treat HIV using outpatient treatment facilities[11].

The need for special precautions to lessen the risk of HIV transmission to health care workers also supports a policy of concentrating care in a few centres. Precautions against transmission may involve the use of special equipment and procedures. The fixed costs of acquiring new equipment and adopting new procedures in a hospital may be considerable[35]. Concentrating cases can reduce the average cost of precautions per case. Concentrating cases may also enhance the value of these precautions by encouraging health care workers to cooperate with safety guidelines. Some evidence suggests that compliance with safety precautions is greatest in areas with the highest prevalence of AIDS cases – where medical workers are at highest risk[36].

Concentrating facilities for care of HIV patients in a few centres may improve quality and reduce costs. As physicians gain experience with the disease, they may choose fewer, more effective treatments, they may have a better sense of when to discharge a patient from hospital, and they may know of more alternative facilities that can take patients. Gains from experience across hospitals, though, do not seem to translate into gains from concentrating patients into dedicated units within hospitals. Experiments with dedicated AIDS units show little improvement in costs or quality of care relative to patients cared for in other parts of the same hospital[37].

The possible presence of economies of scale in AIDS treatment suggests that careful health facility planning can reduce the epidemic's costs and suggest a possible source of upward bias in the existing estimates of AIDS costs. Simple linear extrapolations from the cost of treating the first few cases encountered in a country may greatly overstate the full cost of well-organized treatment.

Health manpower planning should incorporate the effects of HIV on provider recruitment

Health care providers who serve patients with HIV infection risk exposure to the virus. Unlike other conditions to which health providers may become exposed, HIV infection cannot be cured or avoided through vaccination. Given the devastating impact of HIV transmission, health providers' reluctance to treat patients with the disease is not surprising.

Problems in personnel recruitment have increased over time. Early in the epidemic, awareness of the risk of transmission was limited[38]. Furthermore, medical personnel may have been interested in being on the forefront of treatment of a new disease. Since then, despite costly precautions to avoid HIV transmission, some medical workers have been infected through occupational exposure[39]. As the number of cases and perceptions of the risk of transmission have increased and the lure of medical innovation has diminished, medical personnel recruitment has been affected[38].

In recent polls, many doctors express an aversion to treating AIDS patients and state that they would not care for these patients if they had a choice[40, 41]. Hospitals with large AIDS caseloads have had trouble recruiting medical staff[42]. Similarly, interest in specialties that now involve caring for many AIDS patients appears to have declined[43].

The cost implications of recruitment difficulties can be monetized as the compensating differential need to attract providers to care for HIV patients. Studies have not yet estimated the magnitude of this compensating differential, but polling data and recruitment evidence suggest that it may be substantial. Health planners should take into account the possibility that recruitment of personnel will become increasingly difficult and costly as the epidemic progresses.

Prevention efforts should be targeted to high-risk groups and areas

The first cases of AIDS reported in the United States were among homosexual men and intravenous drug users. Thirteen years later, these two groups continue to

account for about 80% of all newly diagnosed cases[44]. The epicentres of the epidemic in the early 1980s were San Francisco, Los Angeles and New York City. Today, these three cities account for almost a quarter of newly diagnosed cases. Although the epidemic has spread beyond the original risk groups and to other regions of the country, it remains heavily concentrated in the populations and places where it began. The growing number of cases among heterosexuals can often be traced back to contact with a member of the traditional risk groups. This epidemiological pattern suggests that the benefits of prevention and control efforts targeted at traditional risk groups may persist over time.

A growing body of evidence also suggests that prevention and control strategies targeted at lower risk groups may be quite ineffective. Despite considerable concern over the possible spread of the AIDS epidemic in the United States to groups other than homosexual men and injecting drug users, few changes in the behaviour of low-risk groups have been documented. While behaviour changes rapidly in response to perceived increases in risk in local communities, perceptions of general risk do not seem to affect behaviour[45]. Changes in behaviour have been greatest among urban homosexual men, followed by injecting drug users. Lower-risk groups, particularly young heterosexuals, although they are quite well-informed about HIV, show few changes in behaviour in response to the epidemic[46]. Costly efforts to encourage changes in behaviour in these groups, including public educational campaigns, have had limited effects on behaviour. While some increase in condom use among heterosexuals has occurred, most of this change appears to have followed early media reports about the epidemic. US Surgeon General Koop's public mailing of AIDS information to all American households in 1988 did not affect measured risk behaviours significantly[47].

Most educational campaigns for AIDS prevention among heterosexuals in the United States encourage condom use. Condoms are inexpensive relative to income in the United States, and in some schools and universities are provided free. Nonetheless, as recently as 1988, fewer than 20% of never-married women in the United States who reported using contraception used condoms[48].

These results suggest that the nonmonetary costs of changing sexual behaviour are high. Unless people perceive a significant risk of infection, they may rationally choose not to change their sexual practices[31]. Combined with the evidence that the epidemic has remained concentrated at its original sites, the reluctance of those at low risk to change their behaviour suggests that the most cost-effective approach may be to target prevention and control efforts at high-risk groups.

Groups that face a high risk of infection will change their behaviour if they have information and opportunity

In 1986 researchers forecast that 87,000 new AIDS cases would be diagnosed in the United States in 1991. The actual number of cases diagnosed in 1991 missed this mark by 41,000. The reduction in AIDS incidence by 1991 occurred because groups at high risk of HIV infection had made massive changes in their behaviour to avoid infection[49].

Estimates of behaviour change suggest that news about AIDS led to a rapid and profound change in the sexual behaviour of homosexual men[50]. One report finds that the proliferation of information about the epidemic resulted in a threefold to fourfold decrease in rates of high-risk sex among this group[51]. Studies of injecting drug users also find evidence of substantial changes in behaviour. Towards the end of 1983, drug users had reduced needle-sharing and increased their efforts to clean needles between injections[52].

These results suggest that even before major government campaigns, individuals who faced a significant risk of infection took steps to reduce their vulnerability. For homosexual men, these changes in behaviour led to a notable reduction in the spread of the disease. By 1991, cases among homosexual men were about one-third lower than had been projected[49]. Unfortunately, behavioural change among injecting drug users had smaller effects on the spread of the epidemic among this population. Effective behavioural change for members of this group required access to costly goods and services – drug treatment programmes, bleach, clean needles – that may have been unaffordable given their incomes. Public funding for programmes aimed at injecting drug users has been mired in controversy and slow to respond to the epidemic[53].

Evidence from high-risk groups in the United States suggests that information about HIV can spread more rapidly than the virus itself. People who perceive themselves as vulnerable to infection do make efforts to change their behaviour. For many, however, public support is necessary if these behavioural changes are to be translated into reductions in infections.

Complacency is dangerous, behaviour changes are difficult to maintain

While the evidence of changes in behaviour among high-risk groups is encouraging, some recent studies document increases in dangerous behaviours among these groups. These studies are the mirror image of those that found reductions in high-risk behaviour early in the epidemic. Then, as the perceived risk of infection increased, vulnerable populations changed their behaviour. Now, as the perceived risk of infection

declines, vulnerable populations show signs of resuming their preepidemic behavioural patterns[31 50].

High rates of risky sexual behaviour have been documented among homosexual men in small cities, where AIDS rates are low, and among young homosexual men[54]. The HIV epidemic has not led to a fundamental change in sexual habits. Rather, homosexual men in communities that have not been severely affected by the epidemic, whether because they are geographically isolated or because they include men who have come of age since 1981, continue to practice high-risk sex. Some studies also document reversions to high-risk behaviour among homosexual men who had changed their behaviour earlier in the course of the epidemic. These studies are consistent with the view that the nonmonetary cost of safe sex is high, and that only those who perceive a significant risk of developing AIDS will find that the benefits of changing behaviour outweigh the costs. Any reductions in high-risk behaviour should be cheered, but health planners should beware of the potential for recidivism.

Community participation should be encouraged

Among both homosexual men and injecting drug users, significant information dissemination leading to behaviour change occurred through community action. Community organizations sponsor educational activities and take an active role in marshalling public funding for AIDS research and prevention[20]. The epidemic's focus on traditionally marginalized groups, who may not trust public authorities, makes the role of community groups in education especially important.

Community organizations have also been at the forefront of treatment innovations. The development of out-of-hospital facilities for the care of AIDS patients was largely the work of voluntary community groups. Especially in the first decade of the epidemic, volunteers provided a significant portion of the care patients received[20]. Community organizations and voluntary labour have substantially reduced the cost of preventing AIDS and caring for AIDS patients in the United States.

Some researchers have expressed concern that the potential of community organizations and volunteers may soon be exhausted[20]. These organizations draw staff and resources from the very communities that have been hardest hit by the epidemic. As more community members succumb, the burden on those who remain healthy may become excessive. Without the participation of community organizations, the quality of educational interventions and of care offered to those with AIDS will suffer, and the monetary costs of these activities will rise.

The US experience suggests that community groups can contribute greatly to the task of coping with the HIV epidemic, but that these groups can become exhausted. Health planners should encourage the development of community groups and their participation in AIDS prevention and care. They should also provide both encouragement and tangible support to these groups as the epidemic continues.

Efforts to reduce stigma and discrimination against people with HIV can reduce the cost of the epidemic

HIV is not infectious in ordinary workplace or educational settings. Unfortunately, fears and misconceptions about the disease abound. In 1987 one-third of Americans polled believed that an HIV-infected worker should be fired and one-quarter stated that they would not work with a person who had AIDS[3]. Parents throughout the United States have tried to keep HIV-infected children out of schools[5]. Such attitudes may lead to unwarranted and costly dismissals of productive people and to increased costs for child care and education. On average, HIV-infected people carry the virus for ten years before manifesting symptoms. The present value of foregone income over the remaining healthy lifetime of an average American male full-time worker who loses his job when he becomes HIV-infected is almost $250,000 (based on mean money income in 1991 of year-round, full-time male worker discounted at 5% over ten years [55]. Estimate of healthy life expectancy is reported in ref. 3.).

Efforts to educate the general public about the realities of HIV may have succeeded in reducing the stigma associated with AIDS[56]. By 1991, the number of people reporting that they believed an HIV-infected worker should be fired and that they would not work with a person who had AIDS had dropped to one in five and one in six, respectively[3]. Nonetheless, considerable stigma and misinformation remain[57]. Information campaigns designed to reduce discrimination may pay off in better use of productive resources.

Economic policy should redistribute the burden of HIV costs from affected regions to the nation as a whole

The lifetime cost of treating HIV infection in the United States is more than $100,000 (ref. 11). The almost 145,000 people who contracted AIDS in the United States during the 1980s were predominantly young, productive men with many years of earnings ahead of them[44]. Nor are there readily available substitutes for these men. During the last half of the 1980s, unemployment rates in the United States for men over 20 averaged just over 5% (ref. 56). Despite the high cost of treatment, the productivity of those who contracted

AIDS and the relatively inelastic supply of labour in the United States, the epidemic has not had a devastating effect on the macroeconomy of the nation as a whole. The estimated lifetime federal and state tax revenue losses associated with the 35,000 Americans who died in 1992, for example, amounted to only 1.5% of the revenue of the federal government in that year[1, 5, 44]. The medical care costs of AIDS account for a similar portion of total United States health expenditures[13].

The relatively benign effect of the epidemic on the macroeconomy of the nation as a whole contrasts with its devastating effects on particular regions, especially on communities within these regions[18, 20]. In New York City and San Francisco, the total number of AIDS cases diagnosed since the beginning of the epidemic amount to more than 1 case for every 150 current residents[44]. In some New York City neighbourhoods, the number of AIDS cases diagnosed in the 1980s amounted to one for every 55 residents[20]. The costs of treatment have wrecked the finances of local hospitals and forced state policy-makers to make difficult decisions about resource allocation[20, 58].

The nature of transmission of HIV suggests that the epidemic will remain concentrated in particular areas of the country and in particular communities. The gulf between the ruinous effects of the epidemic on these areas and communities and its less severe effects on the United States macroeconomy highlights the importance of redistributive policies in coping with the epidemic. Effective policies will help these communities bear the epidemic's social and medical costs and, through prevention and control measures, reduce the spread of the epidemic to other areas. Thus, both compassion and self-interest dictate that nations assist those areas suffering under the weight of the epidemic. At least in the United States the economic effects of the epidemic spread across the nation as a whole will easily permit such redistributive actions.

Conclusions

Economic and social research in the United States can improve our understanding of the epidemic in other parts of the world. In terms of measuring the costs of the epidemic, United States research suggests that conventional methods of accounting may overestimate some aspects of costs by failing to recognize cost-saving methods of care, including outpatient therapy and treatment centres, that may develop as the epidemic progresses. It also suggests that many measures of economic impact often seriously underestimate the costs of the epidemic by failing to include pre-AIDS costs, the costs of related opportunistic infections, the costs of HIV prevention and control, and the increased cost of recruiting medical personnel. American research provides cause for both hope and alarm in terms of HIV prevention. High-risk groups, particularly those in active and well-supported communities, have reduced their levels of dangerous behaviours remarkably quickly. Furthermore, educational efforts may be effective in reducing the level of discrimination people with AIDS encounter. By contrast, reversions to risky behaviour are common even in groups that had succeeded in changing their behaviour, and groups that perceive themselves to be at low risk have hardly responded to the threat of AIDS. Perhaps the most important lesson of the United States experience is that the effects of the disease are highly localized. National policy must be targeted at discrete, severely affected communities.

Lessons from the United States may be valuable. At the same time, one must recognize that the United States epidemic differs substantially from that in other countries. Most people with AIDS in the United States are homosexual men and drug users. Prostitution and heterosexual sex are not important vectors of transmission in the United States. The structure of economies and labour markets varies profoundly among the three major regions of HIV prevalence: the United States, Sub-Saharan Africa, and Asia. Cultural factors, including the role of community organizations and social structure, differ immensely by country, and these play a critical part in determining how quickly the spread of the epidemic can be arrested and how much it will cost to care for those who become ill. These differences may diminish the transferability of United States knowledge on the economic and social effects of AIDS, but as the epidemic rages, it makes sense for researchers throughout the world to glean what they can from each other's work.

Making the blood supply safe from HIV: The Sri Lankan experience

Nandrani S. de Zoysa

14, Bodhiraja Mawatha, Jayanthipura, Battaramulla, Sri Lanka

SRI LANKA is an island situated in the Indian Ocean with an area of 65,610 km^2 and an estimated population of 17.5 million. The National Blood Transfusion Service (NBTS) of Sri Lanka is managed by the government and funded by an allocation from the Ministry of Health budget. This service, which was established in 1962 with a central blood bank and one regional blood bank, has now expanded to include 47 regional blood banks.

The central blood bank, which is located on the premises of Sri Lanka's premier hospital, fulfils the hospital's blood needs, including those of Accident Service and a nearby maternity hospital. It also serves as a reference centre for all the regional blood banks and as a training centre for medical, nursing and technical personnel appointed to the NBTS and their undergraduate and postgraduate trainees. The regional blood banks are located at teaching, provincial, base and district hospitals and handle the blood needs of those hospitals. The central blood bank and regional blood banks also undertake serological investigations, including antenatal serology, for hospitals. The NBTS collects blood from approximately 100,000 donors annually. Facilities for preparing and storing all blood components are available at the central blood bank and eight large regional blood banks, and facilities to prepare a few basic blood components are available in seventeen of the smaller regional blood banks. Blood is tested for syphilis, malaria, hepatitis B and HIV.

Table 1. HIV/AIDS status in Sri Lanka, 31 December 1993

120 HIV/AIDS	→	20 Foreigners
	→	100 Sri Lankans
100 Sri Lankans	→	• 74 Males
	→	* 26 Females
Male:Female ratio		3:1
100 Sri Lankans	→	33 AIDS cases (28 dead)
	→	67 HIV-positive
33 AIDS cases	→	25 Males (22 dead)
	→	8 Females (6 dead)
67 HIV-positives	→	49 Males
	→	18 Females

• 18 Seamen; • 9 Blood donors; * 2 following blood transfusions abroad.

The HIV and AIDS situation

The first case of AIDS in Sri Lanka was detected in September 1986, in a foreigner who became ill while on vacation; the first Sri Lankan with HIV, a male homosexual who became infected when living abroad, was diagnosed in April 1987. Since then, as of 31 December 1993, 120 people had been found to be HIV-positive. Of these, 20 were foreigners and 100 were Sri Lankans (74 men, 26 women). Thirty-three of the Sri Lankans developed AIDS and twenty-eight of them are now dead.

The first HIV-positive blood donor was detected in January 1989, and as of 31 December 1993, a total of nine blood donors had been confirmed as infected with HIV out of a total of some 388,000. All the infected blood donors were men, and most were first-time donors.

Safety of the blood supply

Testing individuals for the HIV antibody cannot assure a safe blood supply, because an individual who donates blood during the period after HIV has entered the body but before the antibody appears in the blood can transmit the virus through blood transfusion. Although 95.0% of HIV-infected people test positive within three months of infection and a further 4.5% test positive within six months, 0.5% remain negative for as long as several years. Therefore, simply testing blood for HIV antibody prior to transfusion will not eliminate the transmission of HIV infection through blood. To make the blood supply as safe as possible, testing for the HIV

Table 2. HIV infection in blood donors in Sri Lanka (20 April 1988 to 31 December 1993)

HIV-antibody-positive donor	Sex	Date of testing	Blood bank where blood was donated	No. of donors tested from April 1988
1	Male	22.01.89	Central Blood Bank (Mobile Unit)	21,973
2	Male	24.04.91	Regional Blood Bank (Kalutara)	137,900
3	Male	03.10.91	Central Blood Bank	173,956
4	Male	12.12.91	Regional Blood Bank (Panadura)	188,681
5	Male	03.08.93	Central Blood Bank	342,848
6	Male	01.09.93	Regional Blood Bank (Castle Street Hospital Colombo)	351,489
7	Male	25.10.93	Regional Blood Bank (Negombo)	367,889
8	Male	05.11.93	Central Blood Bank (Mobile Unit)	372,415
9	Male	27.11.93	Regional Blood Bank (Ragama)	380,000

Table 3. HIV antibody testing in blood banks in the National Blood Transfusion Service 20 April 1988 to 31 December 1993

Year	No. of blood banks testing blood	Percentage of total blood supply covered	No. of blood donors tested	No. of positive blood donors detected
1988	CBB + 13 RBB	25.82	16,426	0
1989	CBB + 18 RBB	60.12	37,686	1
1990	CBB + 32 RBB	91.15	66,353	0
1991	CBB + 36 RBB	99.52	78,543	3
1992	CBB + 41 RBB	99.94	87,461	0
1993	CBB + 43 RBB*	99.96	102,022	5
		Total	388,491	9

*Includes two new RRBs established in 1993.
Prevalence of HIV infection in blood donors = 1 in 43000.

antibody must be considered only as a backup to donor selection, which must be done with meticulous care. The NBTS has adopted a number of strategies to prevent the transmission of the infection to donors during blood donation and to patients through blood transfusion.

HIV infection by blood donation

Instances have been reported from abroad in which blood donors have been infected with HIV during blood donation. This is possible if contaminated lancets, syringes and needles are reused without adequate sterilization. This risk can be eliminated completely by using only disposable sterile items to collect blood. Since 1988 the NBTS has used only disposable sterile items (replacing the earlier practice of reusing items sterilized by high-pressure steam). Therefore, no donor who donates blood at any of the NBTS's 48 blood banks, including mobile units, can contract HIV or any other infection by donating blood. Even the cotton wool and gauze used to clean the blood donor's arm before blood collection is sterilized under high pressure in dressings drums and discarded after use. Sharp bins are used to dispose of lancets, syringes and needles after use to prevent infection through accidental injury to blood donors, blood bank staff and visitors.

HIV infection by blood transfusion

Blood is collected only from voluntary, nonremunerated donors. The former system of partial remuneration was phased out by 1987. However, as in most developing countries, a 'hidden' system exists in which patients asked to get a relative or a friend to donate blood as a replacement for blood that has been or will be transfused to them instead pay money to people to donate

blood for them. This jeopardizes the safety of the blood supply, because these paid donors will not divulge vital information about their health and will donate blood even if they have indulged in high-risk behaviour. The staff responsible for donor recruitment and screening are alerted to this problem during their training and instructed to exclude these donors, or to collect the blood but discard it without informing the donors or the patients if they are unable to reject the donors. Blood for patients is then provided from the stocks available at the blood bank.

During the last five years, the NBTS and Sri Lanka's AIDS Control Programme have arranged confidential circulars, lectures and seminars to instruct staff responsible for blood donor screening and registration about individuals and groups at high-risk for HIV infection.

Blood donors are given a leaflet entitled 'Important message to blood donors – AIDS' which explains about HIV and AIDS infection and appeals for donors to exclude themselves if they belong to one of the high-risk groups listed. Staff are instructed to ask donors if they have read the leaflet prior to registration. If the donor reads the leaflet and goes away, no questions are asked. If the donor has any questions, a confidential interview is arranged with the medical officer. This leaflet was introduced in 1987.

Blood donors have always been required to sign certificates of fitness declaring that they do not have epilepsy, a sexually transmitted disease, tuberculosis, malaria or typhoid. This certificate has just been updated to include heart disease, high blood pressure, stroke, diabetes, cancer, kidney disease, abortion (within six months), and HIV or AIDS. The statements 'I also declare that I have read the leaflet explaining about AIDS and I do not belong to the high-risk groups mentioned in the leaflet' and 'I agree to have my blood tested for HIV (the AIDS virus) and other infections' have been added to this certificate, which the blood donor has to sign prior to registration for blood donation.

NBTS staff have been instructed to examine the forearms of blood donors for injection marks and to reject such donors so as to exclude possible intravenous drug abusers. Staff have also been told to look for skin lesions resembling Kaposi's sarcoma, which is sometimes seen in AIDS patients.

Safer blood and blood products

The NBTS collects blood into citrate phosphate dextrose-adenine blood bags with a shelf life of 35 days, and the blood is processed into blood components. Blood components are cellular and plasma components, which are separated from whole blood by conventional blood bank methods such as centrifuging and freezing. Blood is tested for HIV and other infections prior to transfusion.

NBTS staff question blood donors carefully about their present and previous occupations, travel abroad in the past ten years (including visits to African countries after 1977) and whether they have ever been sailors or in prison. They also look out for foreigners. The earlier practice of rejecting high-risk donors after explaining the problem to them was stopped because blood donors were offended. This was replaced by confidential unit exclusion in late 1991, whereby blood is collected from all donors who are otherwise fit to donate blood, but the blood of high-risk donors is discarded without informing the donor or the patient (if blood was donated for a particular patient), even if the HIV antibody test is negative, and blood for the patient is provided from stocks. Although sometimes a large number of blood units have to be discarded, this has not posed a major problem as yet, because the number of blood donors has increased considerably over the years.

Testing samples of the blood of high-risk donors, i.e. those who tested positive for syphilis or hepatitis B, was started in November 1987, and all 203 samples tested through April 1988 were negative for the HIV antibody.

Routine testing of blood for the HIV antibody using the ELISA technique started in April 1988. By the end of that year 25.8% of the blood collected by the NBTS was tested. This was gradually extended, and currently more than 99.9% of the blood supply is tested for the HIV antibody prior to transfusion. Two regional blood banks are not testing for HIV. These are located in the north in the war zone and cannot obtain a regular supply of test kits because of transport problems. However, these blood banks collect only a few units of blood, which accounts for less than 0.1% of the total blood supply.

At present, blood from the central blood bank and seven regional blood banks is tested for HIV at the anti VD Campaign in Colombo, and two regional blood banks are testing at the anti VD Campaign in Katugastota using the ELISA technique, or the particle agglutination test (Serodia) when ELISA test kits are unavailable. The other regional blood banks perform the HIV antibody test in their own laboratories using either the Serodia test or a quick test (HIV-check or HIV-spot). Trained medical and nursing officers do the HIV antibody test in all but the five regional blood banks that have laboratory technicians. The funds for the HIV antibody test kits were provided initially by the World Health Organization, later by the United Nations Development Programme, and currently are provided by the Asian Development Bank.

If a sample of blood from a donor is found to be HIV-positive, NBTS staff discard the blood even if the blood from the same donor is negative when tested again. If a blood donor is confirmed as being HIV-positive after repeat testing or confirmatory testing using the immunoblot (western blot) technique, this information is

communicated only to the directors of the AIDS Control Programme and the NBTS. The AIDS Control Programme then traces and contacts the HIV-infected blood donor and arranges for counselling. Confidentiality is maintained so that neither the blood bank staff nor the patient (if blood has been donated for a particular patient) are aware that the blood donor has been confirmed as being HIV-infected.

Blood products are plasma fractions that are separated by means of a plasma fractionation unit. This equipment is expensive and is currently not available in Sri Lanka. Therefore, a small quantity of lyophilized factor VIII concentrate (antihaemophilic factor) is imported to treat haemophilia patients who develop reactions to cryoprecipitate prepared locally. To ensure that the antihaemophilic factor is safe, only virus-inactivated products have been imported since 1987. As the products imported from France, Austria and United States before 1987 were not virus-inactivated, a haemophilia register was started in 1988, and haemophilia patients who seek treatment at government hospitals were registered at the central blood bank. As of December 1993, 132 haemophilia patients had been registered, of which 43 had received imported and antihaemophilic factor before 1987. All 132 patients were tested. All tested negative for HIV, but five were found to be positive for hepatitis B.

The NBTS also imports a limited quantity of 5% human serum albumin for patients who develop reactions to plasma transfusions and for use as a replacement fluid for therapeutic plasma exchange. This product is pasteurized and, therefore, is considered safe.

Conclusions

The strategies adopted by the NBTS of Sri Lanka to try to ensure a safe blood supply appear to have been effective because no case of HIV infection following blood transfusion in Sri Lanka has been reported to date. However, with the detection of 100 HIV-infected people in Sri Lanka as of 31 December 1993, and with an estimated 3500 people likely to be infected, resulting in an increased prevalence of HIV infection among blood donors, every effort will have to be made if the NBTS is to continue to provide a safe blood supply.

Ethical issues posed by HIV testing and screening

Ronald Bayer

Columbia School of Public Health, Columbia University, 600 West 168 Street, New York, NY 10027, USA

FROM the outset, the test developed to detect the antibody to the AIDS virus, which was first used on a broad scale in blood banking beginning in 1985, has been mired in controversy[1]. Would groups at increased risk for AIDS be encouraged to take the test? How forceful would such encouragement be? How would those who agreed to be tested be counselled about the test's significance for themselves and others? Would, and could, the results be kept confidential? Would voluntary testing be a prelude to compulsory screening? What would be the consequence of testing for the right to work? To go to school? To bear children? To remain free? Each of these questions would force a confrontation about the relationship between the right to privacy and the protection of the public health and about the roles of voluntarism and coercion in the social response to the threat of AIDS.

Controversy about the HIV test is not foreign to India. The November 1993 issue of the *Indian Journal of Medical Research* published three articles that touched on ethical and policy issues surrounding HIV testing. Mathan[2] argues that the HIV test should be freed of limits imposed by an 'exceptionalist'[3] perspective. 'HIV and AIDS are infectious and should be dealt with exactly as other infectious diseases are being handled. Diagnostic tests are best left to the discretion and judgment of the concerned clinicians[2]. Even this call for a standard of presumed consent, however, does not entail a call for wide-scale mandatory testing. 'Since the availability of HIV testing facilities is limited, the test in any case is not going to be done widely.'

In sharp contrast, Narain *et al.*[4] of the South East Asia Regional Office of the World Health Organization present a strong case for limiting the role of HIV testing in public health practice and for a standard of specific, informed consent because of its unique features: 'Compared to any other type of disease, the issues related to the diagnosis of HIV infection are far more complex.' This plea for 'exceptionalism' concludes by stating: 'Mandatory testing or testing without informed consent is not only counterproductive but also wasteful of scarce resources.'

Finally, Lal and Thakur[5], writing for the National AIDS Control Organization, present proposals then under consideration for its national HIV testing policy document. They too reject testing without 'explicit consent' except for surveillance purposes, where unlinked anonymous screening can assure that no individual is identified.

For an American, writing in a very different ethical, legal, social, economic and epidemiological context to provide simple ethical instruction on HIV testing would be presumptuous. Far more useful, I believe, would be to present a picture of how the ethics of screening have evolved in a variety of settings, thereby alerting readers of *Current Science* to issues that will require attention in the context of a growing AIDS epidemic in India.

In the United States and other economically advanced, democratic societies confronting the AIDS epidemic, a broad voluntarist consensus emerged from the early debates about HIV testing. This perspective drew upon American constitutional traditions and the liberal values that have informed those concerned with medical ethics, as well as upon pragmatic considerations. In part because of the United States' unique and early involvement with the AIDS epidemic and the compatibility of American constitutional values and international human rights standards, this perspective was to have a significant impact on the posture of the World Health Organization's Global Programme on AIDS.

Except for clearly circumscribed circumstances, testing was to be done under conditions of voluntary, informed consent, and the results were to be protected by stringent confidentiality safeguards. In the United States, to underscore the importance of protecting the privacy of tested individuals, the option of anonymity in testing centres was made broadly available.

Screening and behavioural change

Even before the screening of the blood supply had commenced in mid-1985, it was clear that the new antibody test would be enlisted in the effort to achieve the overriding public health goal of mass behavioural change. What was a matter of deep dispute and what has remained a matter of controversy was how much of a role testing would play. For public health officials who faced the daunting challenge of affecting the most intimate behaviours and for whom the legacy of other health promotion campaigns gave little reason for optimism, the test seemed to be a technology that could motivate the desired changes. Those who tested positive could be counselled about the urgent need for behavioural changes

to prevent the spread of HIV. Those who tested negative could be counselled about the importance of self-protection. Opponents of too great a reliance on testing – often representatives of the gay community and of civil liberties groups – were fearful of the social consequences of being identified as infected with HIV. Mass education and individual counselling, they argued, were the crucial options. From this perspective, testing, with all of its technical uncertainties, was too costly and too dangerous.

Over the years the bitter edge has all but vanished from the dispute. Public health officials have recognized that extraordinary changes have taken place in the behaviour of gay men, changes that could not be directly linked to the availability of testing. Such changes have, however, not been uniform. Mass education campaigns have not affected the sexual behaviours of some gay men and many intravenous drug users. What remains a matter of controversy is how aggressively to press for testing among those groups where the degree of behavioural change thus far attained gives cause for concern, or even alarm. Most recently, officials at the Centres for Disease Control have begun to acknowledge that the substantial resources committed to testing and counselling might not be the most effective approach for those at greatest risk.

Contributing to the always fragile consensus on testing for behavioural change has been a recognition on the part of public health officials of the need to win the confidence of those most at risk for HIV infection. To the fears that the confidentiality of test results would be breached, thus exposing those infected to stigma and discrimination, public health officials have responded by embracing the cause of confidentiality and legislation to protect the social and economic rights of individuals with HIV infection[6–9]. Without careful assurances of confidentiality and protection against irrational discrimination, encouraging those at risk to come forward for testing would be impossible.

Screening for clinical purposes

Early in the history of the epidemic, when medicine was all but impotent against the opportunistic diseases that afflicted those with HIV, the question with which some patients and many of their advocates confronted those who proposed antibody testing was: 'Of what benefit will a positive finding be for *me*?' Further, this was not a test like others, that clinicians generally used and that were typically covered by the broad, general consent implied in an agreement to be treated. Rather, critics argued, the antibody test was for social and psychological reasons, more like those invasive procedures for which special consent was required. Faced with such challenges and the undeniable reality of social stigma associated with HIV infection, physicians, their professional associations, and public health officials agreed that an exacting standard of consent to HIV testing was appropriate: specific informed consent was to be sought from patients or their surrogates. To many clinicians, however, such requirements represented an unacceptable intrusion into the therapeutic relationship, a hurdle designed to impede sound diagnostic work.

Now that medicine has made some remarkable advances in its capacity to control the life-threatening illnesses HIV-infected individuals face, given the increasing frequency with which physicians and researchers have begun to promote the prophylactic use of therapeutic agents and given the range of clinical trials for which infected people may be eligible, the picture for patients is very different from what it had been early in the epidemic. Under such circumstances one can answer the question, 'Of what benefit will a positive finding be for *me*?' quite differently than in 1985.

Under such circumstances, clinicians have begun to exert pressure to loosen the requirements for specific, informed consent before testing. In short, they have begun to maintain that the time has come to return AIDS to the medical mainstream[3].

Although one can appreciate clinicians' impatience as expressed by this perspective, resisting the pressure for routine testing without consent is important. In the first place, as much as the clinical picture has begun to change, no definitive therapeutic course is available for people infected with HIV but who are asymptomatic. At the same time, the possibility of stigma and discrimination remains an ever-present threat to the social well-being of the infected. Given these circumstances, arguments for specific, informed consent remain as pertinent as ever[10]. But even if the clinical picture improved dramatically, the moral grounds for insisting on informed consent before HIV testing would not change. It is an established principle of medical ethics that competent adults have the right to decide whether or not to undergo treatment and whether or not to terminate treatments already begun.

Certainly, the principle that limits the physician's paternalistic authority to order therapies in the interest of the patient extends to the authority to order tests that would serve as the basis for commencing treatment. But if respect for the autonomy of the patient requires that physicians exercise restraint, then their ethical responsibility to provide appropriate care now requires that they routinely offer HIV antibody testing to those patients whose social histories suggest an increased possibility of infection and for whom therapy is available and accessible.

Screening for safety

Because AIDS represented the first major infectious disease with which advanced industrial societies had had

to contend in almost a generation, and because the causative agent was not identified until three years after the first cases had been reported, it is not surprising that it provoked considerable social anxiety. Employers, landlords, schools and even some health care institutions evidenced a willingness to exclude those with the new disease. With the discovery of HIV and the development of a test that could detect the antibody to the virus, the potential for discriminatory activity increased despite the epidemiological evidence about how infection is spread.

In the United States, the Centers for Disease Control moved swiftly to contain the irrational impulse toward exclusion[11–13]. The message was clear: HIV could not be transmitted casually and thus no grounds existed for excluding infected individuals who were otherwise capable of performing their expected functions, from their schools or workplaces. In the context of the health care, setting universal blood and body fluid precautions would protect workers not only from HIV but also from the far more infectious hepatitis B. Screening could only provide illusory protection.

Although shameful efforts to exclude or isolate school children with AIDS or HIV infection and cases of discrimination by employers still occur, they are almost universally deplored as irrational, unscientific and retrograde.

The situation in health care has not been so clear-cut. The relatively few cases of transmission as a result of needle sticks[14], and the even smaller number of cases of transmission linked to blood splashes have provoked distress among health care workers, especially among surgeons, obstetricians, nurses and emergency room personnel. Those whose work regularly brings them into contact with their patients' blood feel vulnerable. On rare occasions they have asserted the right to refuse to care for those infected with HIV, thereby rejecting the fundamental principles of medical ethics[15, 16]. Far more frequently they have publicly challenged the adequacy of the recommendations for universal blood and body fluid precautions. They have demanded the right to know whether or not their patients are infected and the right to screen on a routine or mandatory basis for HIV infection. The level of vigilance demanded by the threat of a lethal infection cannot, they have argued, be maintained at all times. Protection requires knowledge of infection. The conflict between public health officials who have declared that universal precautions are adequate and clinicians who have asserted that they are not has not abated.

Haunting the entire debate about screening patients for safety reasons is the spectre of the refusal to treat. Those identified as infected will not simply be treated with greater vigilance. They will be given different care, lesser care, perhaps no care. In the absence of ironclad assurances to the contrary, those committed to protecting the infected will view all calls for mandatory screening of patients as a dangerous first step.

In the coming years, new controversies about screening will surely arise. In each conflict those who confront each other will predictably seek to appropriate the mantle of value-free decision making and will charge that those with whom they disagree have deserted the standards of science. On some occasions, the risk posed by the infected will be understood to be so small and the implications of screening and exclusion so burdensome that even the most cautious will find justifying compulsory testing and imposing restrictions hard. On other occasions the choices will not be clear-cut. Nevertheless, in each case more than 'science' will be involved. Decisions about screening policy will reflect the balance of moral commitments to privacy, reason and communal well-being.

Seroprevalence studies

With the identification of HIV as the aetiological agent of AIDS in 1984, investigators realized that an understanding of the dimensions of the epidemic would require more than a careful detailing of the incidence and prevalence of overt symptoms of the disease. To enable public health authorities to target and evaluate preventive interventions and plan for the health care services that would be required in the future as those infected progressed to symptomatic conditions, knowledge of the incidence and prevalence of HIV infection was critically needed.

Soon after antibody testing became possible, epidemiological specialists and public health officials concerned with the surveillance of the HIV epidemic realized that data based on volunteer studies involving only consenting individuals drawn from high-risk groups such as homosexual men, intravenous drug users, visitors to clinics for sexually transmitted diseases or from low-risk groups were insufficient for monitoring the incidence and prevalence of HIV infection because of selection and participation biases.

Anonymous, blinded or unlinked screening emerged as the method of choice for epidemiologists who sought to overcome the inadequacies of volunteer studies. Such screening would involve blood specimens collected for purposes other than HIV testing under conditions that permanently stripped such samples of personal identifiers. As an epidemiological tool, blinded studies had been used on other occasions to establish vaccination levels in populations and for reference purposes in hospital laboratories.

Because individuals participating in blinded screening could not be identified, researchers in the United States generally believed that the principles of privacy and informed consent were not being violated[17]. However, the very element of blinded studies that appeared to permit testing without negating these principles raised

problems for public health, and seemed to represent a breach of the ethical duty to inform individuals about clinical findings germane to their well-being. In the United Kingdom a leading medical ethicist based his profound objection to blinded studies on these grounds[18].

> We trade on deceit – a minor deceit but undoubtedly a deceit – if without either explicit or implicit permission we start using our patients for the benefit of others. The deceit is compounded if in so using our patients we discover important information that they may wish to know and we have deliberately both failed to find out whether or not they would wish to know it and so organized matters that we cannot pass it on even if they did wish to know.

Such objections were persuasive for a time in Great Britain, and in the Netherlands[19] and Denmark[20], where people have remained deeply suspicious of blinded studies. In the United States, however, such studies proceeded with virtually no dispute.

Those who propose to undertake such studies must now pay attention to the prospects of effective early intervention for those with HIV infection. The issue is no longer one of balancing the public health benefits of blinded studies against the potential benefits of studies that would not preclude the notification of infected people. Those with HIV infection have a clear and immediate interest in knowing that they are infected. The ethical standards that impose upon clinicians a duty to inform their patients may increasingly seem to be at odds with the ethical and professional duty of public health officials to develop the most accurate epidemiological foundations possible for guiding preventive interventions and organizing health care services. Under these circumstances, ensuring that the subjects of blinded seroprevalence studies have access to voluntary, confidential HIV antibody testing with appropriate clinical follow-up will be critically important.

Conclusions

India is beginning to experience a striking and disastrous increase in HIV infection. This epidemiological threat is taking place in a vast and populous nation with limited resources compared to those available to the industrialized democracies. The fundamental ethical challenges presented by the AIDS epidemic in India will basically be no different from those in the United States: to inhibit the spread of HIV infection, to provide medical care to the level permitted by the resources available, and to treat those individuals infected with HIV or diagnosed with AIDS with dignity and respect.

It is within the context of these ethical challenges that India must confront the question of how best to employ the HIV test. Like any other technology it can be used to the advantage of those who are vulnerable or it can be abused, thereby further burdening those most in need of protection, care and respect. How India chooses to employ the HIV test will represent an important measure of its commitment to both the public health needs imposed by the AIDS epidemic and to the human rights that may be compromised in the face of the challenge of a growing epidemic.

ECONOMISTS have a vital role to play in helping public health officials and policy-makers understand the AIDS epidemic and design efficient policies to limit its impact. AIDS is first and foremost a public health problem, but it is a problem with deep economic roots and potentially devastating economic consequences. The main purpose of this article is to document this assertion.

The costs of AIDS

To understand the economic consequences of AIDS, a useful starting point is to examine the costs associated with this disease. These costs fall into four main categories. First are the personal medical care costs associated with AIDS, which capture the costs of detecting, treating and caring for people with AIDS. Second are the nonpersonal costs, such as the costs of blood screening, the costs of information, education and communication, and the costs of basic research on AIDS. Third is the cost of lost output and lost income because of AIDS morbidity and mortality. Fourth are the psychological costs associated with the epidemic, such as the pain and suffering caused by AIDS and the cost imposed upon people who must behave differently to avoid contracting or transmitting HIV.

The first two categories of AIDS costs jointly make up the direct costs of the epidemic, so named because they involve a direct diversion of scarce resources from other uses. The third category is referred to as the indirect cost of the epidemic. It is not an out-of-pocket cost like medical expenditures on AIDS patients. Rather, it is what economists term an opportunity cost, because it reflects the value of lost opportunities to work and produce the goods and services whose consumption yields satisfaction. Indirect costs are just as important a component of the total cost of the epidemic as direct medical costs. The epidemic's psychological costs are rarely discussed or quantified.

The first generation of economic research on the AIDS epidemic has involved measuring the direct costs of HIV and AIDS and the income foregone because of AIDS morbidity and mortality in many countries throughout the world. Every study of this issue of which we are aware concludes that AIDS is an unusually costly illness on a per case basis, for two main reasons. First, many of the opportunistic infections with which AIDS is definitionally associated, such as tuberculosis, pneumonia and cryptococcal meningitis, are costly to treat relative to the cost of treating other common illnesses; and second, AIDS disproportionately afflicts individuals in their prime productive years, thereby causing a considerable loss of income to them and their families.

Economists have estimated that the lifetime personal medical care costs associated with AIDS are more than double India's per capita income, assuming that people with AIDS receive medical care that conforms fully to local protocols for the treatment of AIDS and the opportunistic infections with which AIDS is associated. The income lost because of AIDS morbidity and mortality is estimated to be far greater: more than ten times India's income per capita, in discounted terms[1]. This estimate of the loss of private income should not be confused with social output losses, especially in a labour surplus setting, although the two concepts can be linked. Overall, these estimates of medical care costs and lost income indicate that each case of AIDS is quite costly in India, just as it is elsewhere in the world.

Economic determinants of HIV transmission

The contribution of economics to understanding the AIDS epidemic is not limited to quantifying its impact in monetary terms. Economics also provides a powerful way of examining the pattern of the epidemic's spread. The central idea is that HIV is not spread randomly, as tends to be the case with the bacteria that cause tuberculosis or the virus that causes the common cold. Rather, HIV is most often transmitted as a consequence of purposeful behaviour that often has a strong economic foundation. For example, some of the sex that contributes to the spread of HIV is sold on the street and through brothels[2,3]. As another example, a close connection seems to exist between labour migration and HIV transmission[4–7]. This connection seems to arise because the behaviour of migrants is not easily subject to monitoring by their families and communities, because migrants often have considerable amounts of cash to spend, and because they may be lonely because of being separated from their families. In addition, because migrants are often poorly educated and not closely con-

nected to stable communities, making them aware of the behaviours that put them at high risk for contracting or transmitting the virus that causes AIDS can be challenging. All these factors increase the likelihood of migrants engaging in commercial sex, an activity that puts them at high risk for contracting HIV, and ultimately places their spouses and unborn children at risk.

India has a huge migrant population, both internal and international. For example, rural to urban migration is significant, especially in Maharashtra, Tamil Nadu and West Bengal. So too is the floating population of migrant workers[8]. India is also experiencing substantial cross-border population movements with Bangladesh, Nepal, and to some extent Myanmar, as well as strong migration flows to and from the Middle East and a growing influx of foreign tourists, business people, and others. Add to this a continuing process of economic reform, which is likely to promote the movement of people into, out of, and within India, and the situation is one of continuing and increasing vulnerability to the spread of HIV, especially among the general population.

We conclude from this reasoning and these examples that economists have a key role to play in understanding the nature of the HIV and AIDS epidemic and in assessing its impact. Economics is a crucial ingredient in any explanation of why HIV spreads so rapidly among lorry drivers, fishermen, sailors, construction workers, overseas contract workers, the military, commercial sex workers, injecting drug users, and commercial blood donors. That so many countries throughout the world share this pattern of spread is no coincidence.

Does government have a role to play?

Government intervention in the area of HIV/AIDS encompasses a myriad of activities aimed both at controlling the spread of HIV and coping with the immediate shock of the epidemic and its wide-ranging echo effects. Interventions may be justified on the grounds that they promote efficiency (that is, increase the size of the economic pie) or promote equity (achieve a more desirable distribution of the pie).

Intervention can promote efficiency if one individual's behaviour imposes costs upon others for which no compensation is paid, a market failure that economists refer to as a negative externality. As an example, an externality may arise if a person with AIDS and tuberculosis coughs or sneezes in public, and thereby subjects other nearby individuals to the risk of tuberculosis infection. Costs that are not easily deterred are being imposed without offsetting compensation. As another example, consider women who are powerless to negotiate the use of condoms with their sex partners, a situation that arises in many commercial sex establishments as well as in many marital relationships. To the extent these women are exposed, along with their unborn children, to the risk of HIV infection, costs that are not easily deterred are again imposed without compensation, a classic market failure for which government intervention is a natural remedy.

Intervention may also promote efficiency if private individuals are poorly informed about the risks and costs of HIV transmission. Indeed, under certain conditions the government can improve well-being either by providing information about HIV and AIDS or by adopting tax, subsidy, or regulatory policies that induce people to act as if they had this information.

An equity justification for intervention could arise if the costs of the epidemic fall disproportionately upon the poor[1,9]. If the government deems the ensuing distribution of economic well-being, under which the poor are further immiserized, to be socially undesirable, government intervention aimed either at preventing HIV transmission or redistributing resources is well justified.

Contribution of economic reasoning to policy-making

Even though making a case for some government intervention in the area of HIV and AIDS in Asia's developing countries is not difficult, the complexity of the mechanisms that lead to HIV infection and that determine their social and economic impacts make effective policy-making an especially challenging task. We offer three examples to illustrate this point.

The first example relates to HIV transmission via the sharing of needles among injecting drug users. To reduce the rate of HIV transmission, some policy-makers have suggested reducing the number of drug users by cracking down on the supply of opium. From an economist's perspective, however, destroying opium fields might actually promote HIV transmission, a result exactly opposite to the one desired. This could happen if a reduced supply of opium leads to an increase in its price, which in turn leads habitual opium smokers to cut back on their opium consumption by switching to injection, a far more efficacious mode of opium use[10].

Throughout North America and Western Europe, policy-makers are increasingly responding to the problem of HIV transmission through the sharing of nonsterile injection equipment by establishing needle exchange programmes[11]. Under these programmes, injecting drug users can receive new injection equipment at no charge in exchange for used injection equipment. Needle exchange programmes are controversial because they try to improve the conditions under which illegal drug use takes place, which critics claim promotes greater drug use. Nonetheless, preliminary evidence for the United States suggests that the rate of new HIV infection among injecting drug users who participate in such programmes is lower than the corresponding rate among nonparticipants[12].

As a second example, consider a policy of isolating or imprisoning seropositive commercial sex workers, as India did for a brief period several years ago in a highly publicized case in which 854 commercial sex workers, 457 of whom were HIV-positive, were moved from Bombay to Madras and confined[3]. On the surface, this policy might seem to be a sensible way to curb HIV transmission, because it prevents seropositive sex workers from selling sex. However, it fails to address the demand side of the market for sex, that is, the fact that certain individuals, be they foreign businessmen or native sailors, fishermen or migrant workers, will continue to demand and be willing to pay for sex. Under the economic conditions that currently prevail throughout most of the world, that demand will be satisfied by a new group of women who will supply sex commercially, not because they are social deviants, but because they lack better economic opportunities. Although these women may be seronegative when they enter the sex industry, without information about HIV and without the power to negotiate the use of condoms, they too will become infected and then infect others.

A third example concerns HIV testing. Some policymakers believe that mandatory testing is a useful approach to HIV prevention[13]. Their rationale is that people will respond altruistically to the knowledge that they are HIV-infected by curbing behaviours that put others at high risk of infection, especially if they receive appropriate counselling. Altruism is, however, not the rule in economic behaviour. Selfishness is much more common, and in this context might actually cause HIV testing to promote further transmission as people who learn that they are seropositive recognize that they no longer face a key disincentive to high-risk behaviour: the risk of HIV infection. Although research findings vary, a number of reputable studies have found evidence that positive HIV test results trigger increases in high-risk behaviour, thereby supporting the view that testing may promote HIV transmission[14,15].

These three examples are not meant to suggest that economic reasoning provides a complete explanation of individual decisions about drug consumption, the supply of and the demand for sex, or other high-risk behaviours. They do, however, illustrate one of the hallmarks of economists' approach to policy-making: the need to understand the mechanism that is generating undesirable outcomes as a prelude to effective policy design and implementation.

In the first example, the economics of drug injection suggests that a policy of destroying opium fields might increase drug injection more than it decreases drug use, the net effect being a higher rate of HIV transmission. This reasoning does not, of course, imply that the government should promote opium production as a way to drive prices down and encourage smoking in place of injection. While such a policy might, in principle, curtail the spread of HIV, it would probably do so quite slowly, because heavy drug injectors rarely revert to smoking. More important, it might simultaneously increase the number of drug users, which is clearly not a desirable outcome. However, this bit of economic reasoning does help explain the calls for decriminalizing the sale, possession and use of drugs that one increasingly hears in North America and Western Europe. It also highlights the fact that many practical policies for HIV prevention may conflict with other social goals and policies. For example, needle exchange programmes may increase the number of drug users, early sex education and free contraceptives may encourage promiscuity, condom distribution in the prison system may condone illicit homosexual activity, and policies mandating the use of condoms in brothels may undermine the illegality of prostitution.

In the second example, a policy of imprisoning seropositive commercial sex workers is little more than a temporary solution, what might best be termed a band-aid solution, to the problem of HIV transmission. It ignores both the demand side of the market for sex and the readily available supply of additional sex workers.

In the third example, as already noted, mandatory testing may actually promote HIV transmission. This observation highlights the fact that the HIV epidemic can, in principle, be controlled without identifying a single HIV-infected person. As long as the population behaves carefully, a goal that is presumably promoted by the provision of information, those who are infected will not transmit the HIV and those who are uninfected will not contract it. Testing the blood supply and doing some testing for purposes of epidemiological surveillance may be desirable, but this testing can be done anonymously. Limiting the amount of testing that is done also affords the greatest protection to individual privacy, thereby limiting the ostracism and stigmatization that so often, so needlessly, and so counterproductively accompany the spread of HIV and AIDS.

Contribution of economic tools to policy-making

Good economic reasoning encourages policy-making directed at underlying problems, not at superficial symptoms. Economics also offers a set of tools that are often extremely useful for rational policy-making. These tools, known as cost–benefit analysis and cost-effectiveness analysis, are methods for evaluating the desirability of alternative policy options[16]. Both methods require us to estimate the costs of implementing alternative policies. Cost–benefit analysis also estimates the expected benefits corresponding to each alternative, and the optimal policy is the one that has the highest net benefit, that is, benefits less costs.

Cost-effectiveness analysis is closely related to cost–benefit analysis, except that it stops short of estimating

the monetary benefits of particular policies. Instead, it calculates and compares the cost of alternative methods of achieving a particular qualitative outcome.

As a brief illustration, suppose we wish to compare the following eight programmes for HIV prevention and control: (1) mass education through national television and radio; (2) mass education through the distribution of a one-page AIDS information sheet to every household in India; (3) a special HIV and AIDS information programme for Indian workers and tourists going abroad; (4) a special HIV and AIDS information programme for lorry drivers; (5) a programme to expand the provision of family planning services to unmarried individuals; (6) a programme to treat sexually transmitted diseases (STDs), which is important because STDs greatly increase the risk of HIV transmission; (7) a programme for screening India's blood supply for HIV; and (8) a community-based programme aimed at reducing the demand for drugs and promoting harm reduction among injecting drug users in Manipur and other areas with relatively heavy drug use. Using cost–benefit analysis we would estimate the number of HIV infections that each programme would avert and place a monetary value on those averted infections using estimates of the direct and indirect costs of the epidemic. We would then compare the estimated monetary value of averted infections and of any other expected consequences of each programme, such as control of STDs, fertility reduction, reduced drug use, lower crime rates, and so on, with the cost of each programme. Good programmes are those whose benefits exceed their costs, much like good investments are those that yield positive net returns.

Using cost-effectiveness analysis, we would not place a monetary value on the estimated number of averted HIV infections. We would simply calculate the cost per averted infection under each programme as a way to identify which of them offers the least expensive way to control the spread of HIV. Unlike cost–benefit analysis, which takes multiple programme impacts into account and indicates whether each programme is a good investment or not, cost-effectiveness analysis simply ranks alternative programmes in terms of their economic efficiency in achieving a particular outcome. As cost-effectiveness analysis does not require the monetization of programme benefits, it also requires fewer assumptions and calculations than cost–benefit analysis.

Cost–benefit and cost-effectiveness analyses provide a systematic, sensible and practical way of selecting among alternative policy options. Combinations of options may also be analysed, which is important if programmes complement each other. The analyses may be performed from the point of view of an individual, an organization, or society as a whole, and often yield different results depending upon whose point of view is adopted. Although these analyses are sometimes difficult to carry out because of data limitations and a variety of difficulties inherent in calculating and monetizing programme impacts, this is not always the case, as some recent cost–benefit analyses for China and Sri Lanka on the costs and benefits of screening the blood supply for HIV demonstrate[7,17].

Considerable work remains to be done in applying the tools of cost–benefit and cost-effectiveness analyses to the evaluation of policies designed to promote HIV prevention and control. Especially interesting would be analyses of HIV and STD prevention programmes that involve expanding the distribution of condoms in India and of programmes for both mass and targeted education about HIV and AIDS, especially programmes designed to reach migrants. In the absence of a cure for HIV and AIDS, information about safe behaviour and the necessary motivation to practise it are the only options even remotely resembling a vaccine against HIV transmission. HIV can spread fast, but so too can information. Indeed, information delivered through community-based programmes and channels of influence appears to be the most potent ally available in the effort to control further spread of HIV[18].

Impact of AIDS on economic growth and development

Leaders in the global campaign against AIDS have repeatedly expressed the opinion that the AIDS epidemic is likely to have a substantial – perhaps even a catastrophic – impact on the macroeconomies of developing countries[15, 19–22]. A variety of economic studies support these assertions. These studies indicate that in the hardest hit countries of Africa, the HIV and AIDS epidemic may diminish the annual growth rates of national income by as much as two-thirds of a percentage point, and diminish the annual growth rate of national income per person by as much as one-third of a percentage point through the year 2010 (refs 23–26). In relation to the growth rates of many of the world's economies, two-thirds of a percentage point is not as little as it may seem initially. Also, it adds up over time, which is important given that a biochemical vaccine against HIV infection and a cure for AIDS are nowhere in sight.

The economic simulation models and cost of illness calculations that support the prediction that AIDS will have dire macroeconomic consequences require many assumptions that are difficult to verify, but adopting a more direct approach to examining the impact of the epidemic on the growth rates of income per person is now feasible. We are in the second decade of the world AIDS epidemic, which has progressed relatively far in several countries, especially in Africa. For example, nearly 20% of the adult populations of Uganda and Zambia are infected with HIV. In Zambia, the cumulative number of cases of full-blown AIDS has already

reached 4% of the adult population. With this range of HIV experience, from low prevalence countries like China and Sri Lanka, to medium prevalence countries like India, Myanmar and Thailand, to high prevalence countries like Uganda and Zambia, we may examine whether countries that have experienced more severe AIDS epidemics have also experienced lower rates of economic growth, while controlling for other influences on economic growth and addressing the possible reciprocal influence of economic growth on the spread of the HIV.

Technical issues and other details aside, preliminary calculations based on data for 51 countries reveal that the AIDS epidemic has had only a small and statistically insignificant negative effect on income per person. These results resemble ones derived through similar analyses of the economic impacts of the world influenza epidemic of 1918–19 and the Black Death of the mid-1300s, both of which killed massive numbers of people in extremely short periods of time[28].

With these findings in hand, and given that India already has first-generation estimates of the economy-wide costs of the epidemic, the amount of attention devoted to the macroeconomic impacts of the AIDS epidemic can be reduced. This will give policy-makers and researchers an opportunity to focus greater attention on the impact of the epidemic on particular industrial and occupational sectors, on particular geographic regions, and on particular demographic groups, especially people living with AIDS and their families, women, the poor and other marginalized groups, such as homosexuals and drug users. These are the areas that health policymakers, economists, international organizations, nongovernmental organizations, and others concerned with the social and economic implications of the epidemic need to address most urgently. They involve complex issues that include matters of health, sociology, psychology, law, politics and economics. As research problems, they call for multidisciplinary approaches, mirroring their nature as multisectoral problems from the standpoint of policy design and implementation.

Standard potential of hydrogen electrode

S. Parthasarathy, K. Ramya and V. K. Venkatesan

SPIC Science Foundation, 'Mount View', II Floor, 110, Mount Road, Madras 600 032, India

The basis for determination of standard potential of hydrogen electrode is discussed. The EMF values for five cells, each one having a half cell consisting of a hydrogen electrode with different activities/concentrations of hydrogen ions, the other half cell being either Ag/AgCl or An/AnCl$_2$ of different molalities, are measured using solid ion-transmitting bridge without liquid junctions to calculate thermodynamic activities. It has been concluded that the standard potential of hydrogen electrode is actually zero, as the measured EMF value for the cell Zn/ZnCl$_2$ (0.6299 m)/HCl (1.18 M)/H$_2$ (1 atm), Pt viz. –0.762 V is in accordance with the standard potential of zinc obtained from precise calorimetric data. The various factors that support this conclusion are presented.

RECENTLY it has been demonstrated that it is possible to measure single ion activities using a solid chloride ion transmitter bridge–AgCl bridge. Single ion activities of zinc and chloride in $ZnCl_2$ solutions in molality range 0.1–0.001 were reported[1].

Measurement of single ion activities should lead to determination of absolute electrode potentials. The assumption made for arriving at the standard potentials of various electrode system is that the standard potential of hydrogen electrode is zero. Precise calorimetric data for standard potential of zinc, which is not dependent on any potentiometric value, are available. It should, therefore, be possible to determine the standard potential of the hydrogen electrode using half cell potentials of zinc electrode reported earlier and the standard hydrogen electrode.

The hydrogen electrode used for the potential measurement was equipped with a presaturator, a hydrogen bypass and was designed to be completely immersed in thermostatted bath. The cell set up is described elsewhere[2]. The two hydrogen electrodes were platinized from a solution of 1% chloroplatinic acid containing 10 mg lead acetate with a current density of 30 mA/cm^2 for 10 min. The electrodes were then rinsed with distilled water several times.

For the preparation of solid-ion transmitting bridge, pure AgCl was melted into the bridge in the form of a 'U' tube made from pyrex glass with a capillary of 2 mm bore diameter. The tubes are then heated to 380°C and held at that temperature for 10 h and then allowed to cool.

Table 1. Mean activity coefficient of HCl at 25°C

Molality	Activity coefficient	Molality	Activity coefficient
0.001	0.966	0.5	0.769
0.005	0.930	1.0	0.811
0.01	0.906	1.5	0.898
0.05	0.833	2.0	1.011
0.1	0.798	3.0	1.31

The hydrogen electrode was immersed in water in a thermostat set to 25°C. The thermostat is a Haake D8, Germany capable of controlling the temperature by ±0.1°C. Pure hydrogen is passed to the cell by Hydrogen Generator model No. 8200 of Packard Instrument Company, Canberra.

It is reported by Vogel[3] that a solution of 1.18 M corresponds to unit activity and is supported by literature values[4].

From Table 1, it can be seen that 1.0 m corresponds to an activity of 0.811 and 1.5 m corresponds to an activity of 1.347. So an activity of 1.00 corresponding to molarity of 1.18 m follows from interpolation. Molarity of 1.18 corresponds to an activity coefficient of 0.8475. The modified Debye–Hückel equation (Davies equation) which would give the above mentioned activity coefficient is:

$$-\log\gamma_{\pm} = 0.509 Z_+ Z_- \left\{\frac{\sqrt{I}}{1+\sqrt{I}} - 0.3221\right\}.$$

This equation is acceptable as the empirical constant 'C' for highly concentrated solutions can vary between 0.3 and 0.4 in the formula proposed by Davies[5] for activity coefficient as:

$$-\log\gamma_{\pm} = 0.509 Z_+ Z_- \left\{\frac{\sqrt{I}}{1+\sqrt{I}} - CI\right\}.$$

Hence we chose the value of 1.18 M for preparing a HCl solution of unit activity.

The exact molarity was determined by standard titration technique. The HCl solution of 0.01 m was prepared by diluting the standard volumetric solution supplied by E. Merck India Ltd. Zinc chloride solutions were prepared by dissolving the exact weights of pure zinc in 1:1 HCl, evaporating to dryness and adding the requisite amount of de-ionized water.

If the activity of a solution of zinc chloride is assumed to be 1,

$$a_{ZnCl_2} = 4m^3\gamma_{\pm}^3 = 1,$$

Robinson and Stokes[6] showed that if mean molality and the mean activity coefficient is 1, molality of zinc ion would be $m_{Zn^{2+}} = (4)^{-1/3} = 0.6299$ m. In this high molality range, neither the Debye–Hyckel equation nor the Guntelberg equation will be applicable. Only the em-

pirical equation proposed by Davies is applicable. The single ion activity of Zn^{2+} ion will be equal to 1 from the expression

$$a_{Zn}{}^{2+} = 4m_{Zn}{}^{2+}\gamma_{Zn}{}^{2+}.$$

Since $ZnCl_2$ solutions were prepared with extreme care, the molality variation is ruled out and we have prepared a solution 0.6299 m $ZnCl_2$ to provide for unit activity of zinc ion corresponding to the standard state. This corresponds to an empirical constant C well within the range of 0.2 to 0.3 in the Davies equation, as in the case of HCl solution. Zinc chloride solution of 0.1 m was also prepared by the above procedure.

The instrument used for potential measurement was ORION expandable ion analyser, model No. EA 940, from ORION Research Inc., USA which is capable of handling signals from high resistance sources with negligible IR drop.

The bridges are tested by interconnecting Tacussel Calomel electrode in saturated KCl and Tacussel AgAgCl electrode also in saturated KCl in two different beakers, i.e. the cell

Ag/AgCl, KCl(s)/bridge/KCl(s),Hg_2Cl_2,Hg

The potential was seen to be in keeping with the expected value of 45.6 mV[7].

The hydrogen electrodes were tested by observing the potential of the following cells:

1. Pt,H_2 (1 atm), HCl (0.01M)/AgCl, Ag
2. Pt,H_2 (1 atm), HCl (1.18M)/AgCl, Ag

The observed potentials were 464.8 mV and 222.4 mV (standard potential for Ag/AgCl electrode) respectively and were found to be in accordance with values reported elsewhere[8,9].

It was considered necessary to test the bridge when one of the solutions was acidic as it is well known that the mobility of protons is much higher compared to other ions. For this, the bridge was tested by verifying the potential of the cell

Pt,H_2 (1 atm),HCl(1.18M)/Bridge/HCl(1.18M),AgCl,Ag.

The observed potential agrees with the standard potential of 222.4 mV for the silver-silver chloride electrode.

Table 2. Measured potentials using hydrogen electrode at 25°C

Cell assembly	Potential mV
Pt,H_2(1 atm), HCl(0.01 m)/Bridge/KCl(s), AgCl, Ag	318.0
Pt,H_2(1 atm), HCl(0.01 m)/Bridge/$ZnCl_2$(0.1 m), AgCl, Ag	409.5
Zn, $ZnCl_2$(0.1 m)/Bridge/HCl (0.01 m), H_2 (1 atm), Pt	671.9
Pt,H_2 (1 atm), HCl (1.18 M)/Bridge/KCl(s), AgCl, Ag	199.0
Zn, $ZnCl_2$(0.6299 m)/Bridge/HCl (1.18 M), H_2 (1 atm), Pt	–762.0

In order to determine the absolute potential of the hydrogen electrode, the potential of the following cells were measured and the measured potentials are given in the Table 2.

From the potential measured for cell 1 of 318 mV, if we deduct the well-established reference-electrode potential of 199 mV, we arrive at Pt,H_2(1 atm), HCl(0.01 m) potential of the single electrode system as –119 mV. This half cell is coupled with Ag/AgCl system with 0.1 m $ZnCl_2$ using the chloride ion transmitter bridge in cell 2. The measured potential of cell 2 is 409.5 mV. Substracting the hydrogen electrode potential gives a value of 290.5 mV for Ag/AgCl, $ZnCl_2$(0.1 m) half cell, which is in accord with the earlier measurements reported[1].

The potential of cell 3 was measured and was found to be 671.9 mV., i.e. coupling of the same hydrogen electrode with zinc electrode in 0.1 m $ZnCl_2$ solution through the bridge. Addition of the hydrogen electrode potential gives the potential of the zinc half cell, Zn,$ZnCl_2$(0.1 m) as –791 mV which is in accordance with values reported earlier. These data confirm the consistency of the potential measurements made with solid-ion transmitting bridge in acidic systems.

The zinc system was chosen because it is perfectly reversible with respect to the cation, does not form unipositive ions, does not undergo self corrosion, is highly reproducible and precise calorimetric values are available for enthalpy changes[10–12] which when coupled with entropy data, can lead to the standard potential of zinc from methods other than potentiometric methods (See Figure 1). But the final confirmation can come only from direct measurement from a solution of H^+ ions of unit activity.

The potential of the hydrogen electrode system dipping into a solution of unit H^+ ion activity was connected through a solid-ion transmitting bridge to a saturated KCl solution in which Ag/AgCl electrode was dipped (see cell 4, Table 2). The measured potential of 199 mV is in keeping with the expected value.

When the electrode is again dipped into a solution of unit H^+ ion activity and is coupled to a $ZnCl_2$ solution in which the activity of zinc ion is kept unity (See cell 5 Table 2), the voltage observed is –762 mV which is in accordance with the value derived from calorimetric measurements.

The experimentally observed standard potential of zinc using a solution of unit activity with respect to a zinc ion and HCl solution of unit activity with respect to hydrogen ion is surprisingly in agreement with the calorimetrically determined standard potential of zinc (see Table 2). This shows that standard potential of hydrogen electrode is not an arbitrary zero but is actually zero.

The potential of standard hydrogen electrode is conventionally taken as zero at all temperatures, when the partial pressure of H_2 is one atmosphere and the activity

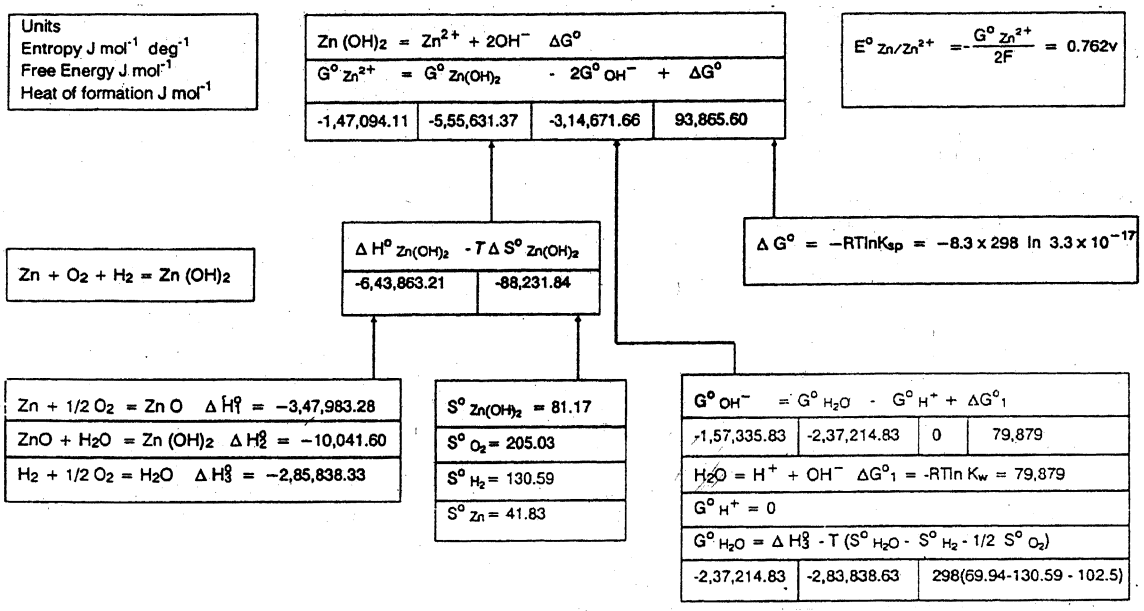

Figure 1. Standard potential of zinc.

of hydrogen is unity. The assumption that the $E^{o}_{H^+/H_2}$ is zero, leads to the consequent result viz. $\Delta G^\circ = 0$ which means that the free energy of reactant and product of the reaction

$$H^+ + e \rightleftharpoons 1/2\ H_2$$

is equal. The possibility of such a situation can be easily understood if one can take into consideration the following facts:

1. Proton, unlike other ions, is of Fermi dimensions (10^{-13} cm)–a Fermion. It is an elementary particle and is a nonconformist ion[13]. Classical theories are not applicable and quantum-mechanical considerations are possible.

2. The classical thermodynamic considerations are not applicable to fundamental particles like electron, proton etc. Therefore, the question of considering the entropy of the electron of the hydrogen atom which on de-electronation will get mingled with conductance or fermi lectrons of platinum, does not arise.

3. Proton's affinity for electron can be seen from the high ionization energy required i.e. 313 k cal.mole^{-1} for removal of an electron from hydrogen atom[14].

4. The heat of formation of hydronium ion H_3O^+ is 170 k cal.mole^{-1} which is considerably less than the ionization energy of hydrogen atom[15].

5. It is suggested that proton most probably exists in solution as H_3O^+ ions but the evidence is not all that certain[16].

6. Platinum serves not merely as an insert conductor but functions more as an efficient electrocatalyst[17] enabling the hydrogen molecule to dissociatively adsorb on the surface and help in the de-electronation of hydrogen atom and electronation of proton. The potential of platinum does not influence the hydrogen electrode potential. Large surface area can also be created[18].

7. The electrical double layer model of Bockris, Devanathan and Muller, which has been accepted as the one that explains many of the observed facts, envisages a layer of water molecules which are highly oriented and has probably a dielectric constant of 6–7 corresponding to a saturated dielectric[19]. The potential of zero charge for Pt in the presence of hydrogen in H_2SO_4 solution is reported[20] to be in the range + 0.11 to + 0.27 Vs standard hydrogen electrode. At the potential of zero charge, the water molecules are arranged with oxygen end and hydrogen end pointed towards the metal surface in an alternate manner to make the contributions of water molecule to the charge as zero. At the potential of standard hydrogen electrode, viz. zero which will be negative to the potential of zero charge, the charge on the Pt surface will be –ve and therefore the water molecules are adsorbed with their hydrogen ends toward the Pt surface. The presence of hydrogen ends adjacent to Pt surface will not enable hydrogen ion to form hydronium ion. As a result of this arrangement hydrogen ions coming out of the platinum surface due to the de-electronation reaction will remain close to the surface (on the metal side) without forming a hydronium ion.

8. From quantum mechanical considerations, proton mobility has been explained on the basis of proton tunneling as proton is a fermion and classical theories cannot be applied[21]. It has been further suggested that proton jump can occur only if the acceptor water molecules orient so that the oxygen, the proton and the unshared electron of the acceptor electron line up. The two processes, proton transfer and water re-orientation involve a time of 10^{-14} and 2.4×10^{-13}s respectively. In the present case, viz. hydrogen electrode having platinum as the inert electrode, the exchange reaction is the electronation of hydrogen ion to give hydrogen atom and de-electronation of adsorbed hydrogen atom to give a pro-

ton. Both these reactions can be expected to take place at such times, probably, shorter than 10^{-14} s. Which is the time required for proton transfer. The proton, formed as a result of de-electronation of hydrogen atom on Pt surface, remains without forming hydronium ion due to the reason mentioned above, close to the platinum surface and is readily available for electronation reaction. The electrons formed due to de-electronation of hydrogen atoms absorbed on the metal surface can become members of the conductance of Fermi electrons of the metal. The electronation of the proton (or hydrogen ion) and de-electronation of hydrogen atom is most probably occurring on the electrode surface and close to the inner Helmhotz plane of the electrical double layer populated by highly oriented water molecules. This exchange reaction is almost a solid state reaction and takes place at very high exchange rates that is necessary for a standard reference electrode. Thus the forward and reverse (or backward) reaction, viz. $H^+ + e \rightleftharpoons H$, can take place with zero free energy change i.e. $\Delta G^\circ = 0$ and consequently E° which is given by $-\Delta G^\circ/nF$ is also zero.

The finding provides a solid base for the electrochemical series built up on the intuitive assumption of W. Nernst that the standard potential of hydrogen can be assigned a value of zero.

Selective denaturation of cytochrome c oxidase by ionic surfactants: Depletion of both the heme *a* residues from the enzyme

Tapan Kanti Das and Shyamalava Mazumdar

Chemical Physics Group, Tata Institute of Fundamental Research, Homi Bhabha Road, Bombay 400 005, India

UV-visible absorption and circular dichroism studies on interaction of ionic surfactants with bovine heart cytochrome c oxidase have been carried out in lauryl maltoside solution. Results showed that addition of the surfactant causes irreversible depletion of heme *a* from cytochrome *a* as well as cytochrome a_3 sites of this membrane protein at physiological pH. This selective denaturation by ionic surfactants is different from the effect of guanidine hydrochloride on this enzyme. Depletion of heme *a* causes complete inactivation of this ubiquitous respiratory enzyme.

IONIC surfactants, such as sodium dodecyl sulphate (SDS), are commonly used for denaturation of proteins[1–4]. There has, however, yet been no report on any systematic study on the nature of interaction of surfactants with hemeproteins. Moreover, cationic surfactants were considered to be less efficient in such denaturation of proteins, which has been disputed recently[5], lending it subject for further investigation. We have recently shown that surfactants, both cationic and anionic, can cause release of heme-NO species from nitric oxide complex of myoglobin[5]. Previous studies have shown that membrane proteins are generally more resistant to denaturation than other proteins. Cytochrome c oxidase (CcO, EC 1.9.3.1) is a mitochondrial membrane protein[6–11] with two heme *a* active sites, strongly ligated to one or two histidines of the protein. This enzyme is generally extracted in active form in neutral surfactants such as lauryl maltoside (LM), Triton X-100 (TX-100), etc. Structure and function of this multifunctional enzyme is a subject of frontier interest in recent years. The present report shows that the highly buried heme *a* groups of this enzyme can indeed be depleted by treatment with both cationic surfactant, cetyl trimethyl ammonium bromide (CTAB) and anionic surfactant, SDS, in lauryl maltoside solution. The biochemical effect of surfactants is a subject of growing concern and the present study demonstrates their fatal effect on this vital respiratory enzyme. Furthermore, this study provides an

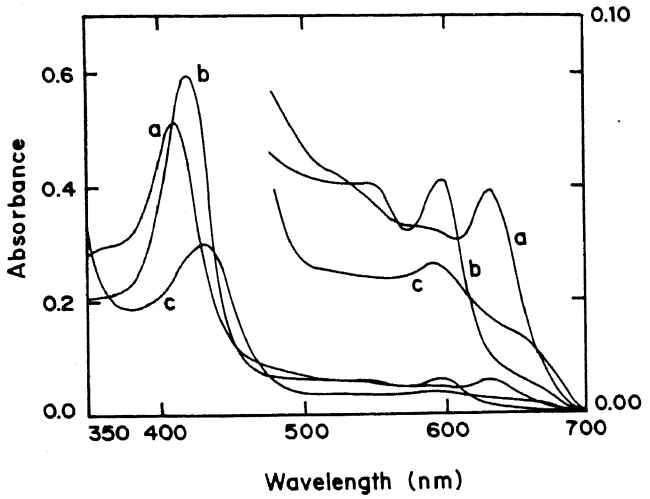

Figure 1. The optical absorption spectra of (a) CTAB-treated CcO. CcO (7.6 μM, 0.1% in lauryl maltoside, 50 mM sodium phosphate buffer, pH 7.4) was charged to a final CTAB concentration of 25 mM. (b) Native CcO spectrum (without CTAB) is given for comparison. (c) Dithionite-reduced CTAB – CcO. Minimal amount of solid dithionite was added to CTAB-treated CcO to effect reduction.

easy method of extracting heme *a* from the enzyme which would otherwise require more drastic conditions. The results have been interpreted in the light of electrostatic and hydrophobic interactions between the surfactant and the enzyme.

Bovine CcO was extracted from ox heart using reported methods[8,12]. The spectrum of bovine heart CcO in lauryl maltoside showed an irreversible change on addition of CTAB or SDS solution to the enzyme. Figure 1 shows the spectrum of CcO (7.6 μM) obtained after addition of 25 mM CTAB (trace *a*) in lauryl maltoside solution. The spectrum of the native enzyme in absence of surfactant is given in trace 'b' (Figure 1) for comparison. The spectrum of CTAB-treated CcO matched exactly with that of CTAB solution of heme *a* separately isolated from the native enzyme (data not shown, see ref. 13). Earlier report[13] of optical spectra of monomeric heme *a* encapsulated in surfactant solution also matched with the spectra shown in trace '*a*' of Figure 1. The Soret peak of CcO undergoes a large blue shift from 421 nm to 410 nm on addition of CTAB. This visible band of CcO at ~ 598 nm also disappears in presence of the surfactant to give a new charge transfer band at 631 nm characteristic of high-spin heme *a* species. Moreover, dithionite reduction of the solution of CTAB-treated CcO (trace 'c' of Figure 1) matched with the reduced heme *a* in CTAB obtained on addition of minimal amount of dithionite to heme *a* solution (data not shown). Similar observations were obtained when CcO was treated with the anionic surfactant, SDS. Unlike ionic surfactants, the neutral surfactants such as, Triton X-100, LM, etc., however, did not have any drastic effect on the spectra of the enzyme. Treatment of guanidine hydrochloride has recently[12] been shown to cause a red shift in the Soret band of CcO. This indicates that the environment around the heme *a* centre on treatment with ionic surfactant is different from that obtained on treatment with guanidine hydrochloride.

The coordination geometry of the two heme *a* centres (cytochrome *a* and cytochrome a_3 sites) in the intact native enzyme are different from each other, giving rise to a slight difference in their optical spectra (broadening of bands) in the native enzyme[9]. However, addition of the ionic surfactant results in complete disappearance of the spectral bands of CcO, indicating that both the cytochrome *a* and cytochrome a_3 sites are depleted from the enzyme to form heme *a* in micelles[14].

In order to further characterize the species obtained on addition of ionic surfactant to CcO, we have measured circular dichroism of the Soret region of CcO at different added concentrations of surfactants. Figure 2 shows that the ellipticity of the Soret region decreases steadily on addition of increasing amounts of CTAB. At surfactant concentrations above 30 mM (with 14 μM CcO) the CD spectra become almost constant with very small ellipticity in the Soret region. The presence of protein environment around the heme gives rise to large ellipticity of Soret band of hemes in hemeproteins[15]. Removal of the heme from the protein and its subsequent encapsulation inside micelles[14] result in an almost isotropic environment around the heme moiety, hence it has negligibly small ellipticity in the Soret region. This result further confirms that the species released on treatment of CcO with the surfactant is heme *a* which gets encapsulated inside the micelles formed by aggregation of the surfactants. The concentration of surfactant required to complete the reaction was found to be almost same for SDS and CTAB, indicating that both of these surfactants are almost equally effective in depletion of heme *a* from CcO. The concentration of guanidine hydrochloride required[12] to diminish the heme CD signal was (> 1 *M*) much more than the surfactant required in the present case, indicating that ionic surfactants are much more effective in releasing heme *a* from the enzyme. Control experiment with pure heme *a*

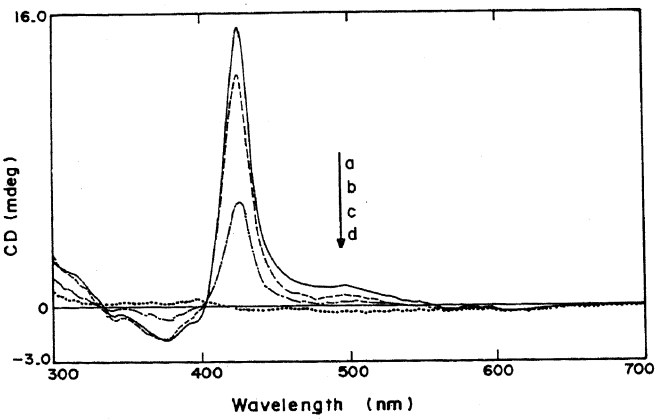

Figure 2. Changes in ellipticity in the visible region of CD spectrum of CcO in 0.1% lauryl maltoside, 50 mM sodium phosphate buffer, pH 7.4, on addition of CTAB aliquots. CcO concentration was 14 μM, cell path length was 10 mm. Curves *a* to *d* represent CTAB concentrations of 0, 12.5, 22.8 and 39 mM respectively.

monodispersed in micelles (data not shown) did not show any significant CD in the near UV-visible region. In the UV region, CD bands around 220 nm were found to diminish up to 36% on addition of the surfactant (data not shown). Similar change in the CD in the 220 nm region has been found on guanidine hydrochloride[12] treatment of CcO. This indicated that the protein possibly gets partially unfolded on treatment with surfactant. However, because of the complexity of the structure of this multisubunit protein, the CD spectra does not provide any quantitative information regarding the unfolding of the structure.

CD and optical spectra of the cyanide complex of CcO (CcO – CN) have also been studied in presence and absence of ionic surfactants. The spectra of the cyanide complex were recorded within one hour after addition of buffered (pH 7.4) KCN solution to CcO when cyanide binds mainly to the cytochrome a_3 site[9]. The major Soret CD peak of CcO – CN was observed at 427 nm, which vanished on gradual addition of SDS or CTAB solution. The optical spectra of surfactant-treated CcO–CN matched quite well with the cyanide complex of heme *a* in CTAB. This result indicates that, addition of ionic surfactants causes breaking of iron–histidine bonds in cytochrome *a* as well as in cytochrome a_3 and results in formation of isolated heme *a* in micellar solution. Walter *et al.*[16] observed a partial spin state conversion of cyt *a* by incubating CcO in higher lauryl maltoside concentration at 40°C. A blue shift of Soret band and formation of a charge transfer band at 630 nm at the expense of the α-band (at 598 nm) was ascribed to a low to high spin transition of cyt *a*, probably because of axial Fe–N bond cleavage[16]. Our results show that this type of transition is complete by treating CcO with SDS or CTAB.

In order to characterize the heme *a* species obtained on treatment in micelles, NMR spectra of heme *a* in CTAB solution at pH~2 (Figure 3, upper spectrum) showed highly down field shifted broad signals due to the heme protons (possibly heme methyl protons). The paramagnetically shifted signals in CTAB solution of heme *a* are similar to those obtained from a $CDCl_3$ solution of heme *a* (lower spectrum in Figure 3), which is typical of high-spin Fe^{3+} heme species. The heme proton signals in micellar solution are generally very broad[14] as observed in the present case. Thus the heme *a* species released on treatment with CTAB on CcO is possibly a high-spin heme *a* complex with axial ligands water and hydroxo ion. The line width of the paramagnetically shifted heme proton signals broadens because of fast ligand exchange at ambient pH, hence they could not be detected at ambient pH using the 500 MHz NMR spectrometer.

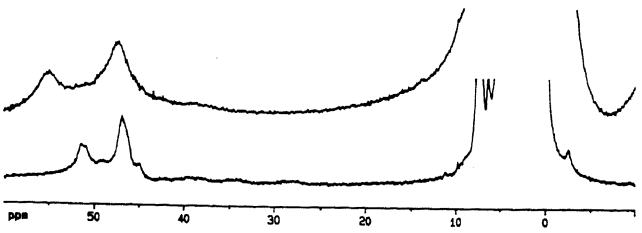

Figure 3. Proton NMR spectrum of heme *a* (~0.4 mM) in $CDCl_3$ (lower trace) and in 30 mM CTAB, 50 mM sodium phosphate buffer, pH~2 (upper trace) in D_2O. Temperature was maintained at 30°C. A multiple frequency irradiation pulse program was used to simultaneously decouple water and CTAB proton resonances.

The present study, thus, demonstrates that ionic surfactants can cause irreversible release of heme *a* from cytochrome c oxidase. The deactivation of CcO and release of heme *a* by CTAB or SDS possibly involves electrostatic binding of the ionic surfactant to the enzyme. Both cationic and anionic surfactants possibly bind to the enzyme surface around its heme crevices to cause heme release. As the charged head groups of surfactant molecules anchor to the enzyme, their hydrophobic tails may interact with the hydrophobic amino acids and break the structure of the enzyme. The iron–histidine bonds possibly become severely weak because of the change in protein structure in the vicinity of heme centres, leading to release of heme *a* out of the enzyme. The heme *a* released from CcO is structurally different from the heme in other hemeproteins. The present method may help in designing heme reconstitution procedures with heme *a* and other hemes in CcO as well as in other hemeproteins.

Evaluation of haemorheological, biochemical and microcirculatory parameters in young smokers

Ranjeet S. Ajmani*†, R. R. Puniyani and Varjeet S. Khanuja****

*National Institute of Health, Gerontology Research Centre, NIA, LCMB, 4-B-12, 4940 Eastern Avenue, Baltimore, MD 21224, USA
**School of Biomedical Engineering, Indian Institute of Technology, Powai, Bombay 400 076, India

We studied 44 young smokers and 40 controls, all male, for haemorheological, biochemical, physiological and microcirculatory parameters. This study was conducted between January 1994 and December 1994. All the smokers have been smoking 13–18 cigarettes per day for the last three years. None of them were taking any medicine nor did they have any major health problem which could affect the results of our study. The results of our study clearly indicate that smokers have disturbed haemodynamic profile as compared to normal controls. This could result in worsening of blood flow condition, leading to development of various disorders.

THE fact that cigarette smoking affects flow behaviour of blood has been well-documented[1]. The hazard of smoking greatly depends on the way of puffing and inhalation, and also on the number of cigarettes smoked per day[2]. It is composed of more than 4000 substances which have diversified adverse effects on the body. It contains nicotine, tar, polynuclear aromatic hydrocarbons, phenol, cresol and *N*-nitrosonornide, benzol in particulate phase, while the gaseous phase contains carbon monoxide, hydrocyanide, ammonia, acetaldehyde, various oxides of nitrogen and acrolein[3]. Out of these, nicotine is most characteristic of tobacco. It is an alkaloid whose inhalation is known to trigger the secretion of vasopressin, a potent vasoconstrictor hormone, with a possible action on coronary arteries. It also stimulates sympathoneurnal and sympathoadrenal activity and influences systolic blood pressure, heart rate and platelet aggregation. A study conducted by Arnow *et al.*[4] found that smoking high nicotine cigarettes causes rise in blood pressure, heart rate, left ventricular end diastolic pressure, coronary sinus, and in arterial and venous carbon monoxide levels, simultaneously causing a decrease in coronary sinus and in arterial and venous oxygen partial pressure levels with a partial recovery within 30 min. Another component is carbon monoxide, which has an affinity 245 times greater than oxygen and, therefore, reduces oxygen supply to the heart and increases the chances of coronary heart disease. This risk is 20 times if the carboxyhaemoglobin (COHb) level is 5% or more[5]. In patients with underlying coronary heart disease, smoking enhances greatly the incidence of acute myocardial infarction and sudden death. Premature coronary artery disease and mortality arising from it increases progressively with the number of cigarettes smoked and the fatal and nonfatal coronary artery disease (CAD) is 60–70% higher in smokers than in non-smokers.

Due to the more viscous blood, there is a stage of stagnation and deficient oxygen supply to the tissues, leading to hypoxia[6]. This reduced oxygen supply leads to: 1. lowered redox state, 2. rapid glycogen utilization, 3. increased osmolality and swelling of cells, and 4. metabolic acidosis.

Metabolic acidosis has a very strong negative effect on the structure and functions of red blood cells. The slower the blood flow in the capillaries, greater is the internal viscosity of the red blood cells and greater the chances of breakdown of haemodynamic mechanisms at macro-and microcirculatory levels. This decreases further the oxygen supply to the tissues, leading to hypoxia and further decrease in pH. Hypoxia stimulates the production of red blood cells, i.e. increase in haematocrit. Haematocrit is one of the strong determinants of blood viscosity. Gagnon *et al.*[7] found that increase in haematocrit coupled with blood viscosity has serious effects or organ perfusion. Thus, a vicious circle sets in which leads to further deterioration of blood flow, making smokers more susceptible to development of vascular disorders.

Indian Institute of Technology (IIT) Bombay is a residential campus where graduate and postgraduate students stay in different hostels. The total student population is about 2500. For conducting this study, students from different hostels were contacted and briefed about the nature of the study. About 152 students expressed their willingness to participate in this study. Only 44 smokers who did not have any major health problems and at the same time did not have any other addiction like alcohol/tobacco chewing, etc., were selected for this study. None of them were taking any treatment, particularly aspirin, at least two weeks before the laboratory tests were performed. All of them were smoking 13–18 filtered cigarettes/day for a variable period of 2–3 years. Out of 152 students, 40 were selected as control group, as they had not smoked cigarettes so far and also were clinically normal subjects. For getting their details and thorough medical, family and personal histories, a questionnaire was used. On the day of blood collection, their blood pressure, pulse rate and weight was taken. Arm blood pressure was taken under supine condition after 10 min of rest, using sphygmomanometer and peripheral

SBP/DBP: Systolic blood pressure/Diastolic blood pressure;
Subjects from both categories were males.

pulse was palpated. To minimize variability, one subject from each group was examined each morning. Details of these subjects are given in Table 1.

Blood collection: About 10 ml of venous blood was drawn from antecubital vein using a plastic syringe with 21-gauge stainless steel needle with minimal suction. Out of 10 ml, about 6 ml was anticoagulated with dipotassium salt of ethylene diamine tetraacetic acid (EDTA) 1.8 mg/ml and about 4 ml with citrate (3.8%). Citrated blood was used for platelet aggregation study. The blood sample of the subjects was collected in the morning between 9.30 and 10 a.m. (to avoid any diurnal variations), after 8 h of fasting, in the Laboratory of Haemorheology and Microcirculatory Sciences, School of Biomedical Engineering, IIT, Bombay.

The sample was analysed within 2 h of collection as per recommendation of International Committee for Standardization in Haematology[8–10]. The following parameters were investigated:

Hemorheological parameters: Whole-blood viscosity, plasma viscosity, red-cell rigidity, red-cell aggregation and platelet aggregation.

Biochemical parameters: Haematocrit, erythrocyte sedimentation rate, total proteins, fibrinogen, albumin, cholesterol and triglycerides.

Physiological parameters: Blood pressure, pulse and weight.

Microcirculatory parameters: Transcutaneous oxygen tension and skin blood perfusion.

Whole-blood viscosity, plasma viscosity and red cell rigidity were measured by using Contraves LS-30, as performed by Ajmani *et al.*[11]. For the measurement of red cell aggregation, haematocrit, platelet aggregation, erythrocyte sedimentation rate, cholesterol triglycerides and plasma protein the method of Puniyani *et al.*[12] was used. Biochemical parameters like plasma albumin, total proteins, cholesterol and triglycerides were estimated by using M-10 autoanalyser. Fibrinogen estimation was done using the method of Ratnoff and Manzie[13], where the fibrinogen present in the plasma is converted to fibrin by the action of thrombin and subsequently boiled with sodium hydroxide. Its tyrosine content is estimated using the Foil–Ciocalteu reagent.

For simultaneous flow dynamics and oxygenation studies, the subjects were called in the evening as they had to attend the regular course classes in the morning. Moreover, since the study of these parameters takes at least 2 h for each subject, evening was the most convenient time to carry out this study. These studies were carried out in nonfasting state.

The Periflus PF 3 laser Doppler perfusion monitor (LDPM) was used for continuous monitoring of local microvascular blood flow as per Schubert *et al.*[14].

The transparent transcutaneous triple sensor/monitor was used for measurement of oxygen tension ($TcPO_2$) and, simultaneously, flux pattern (flow/velocity) by laser Doppler equipment. The TTC-45 triple sensor is compatible with Periflux PF-3. Oxygen tension was measured by AVL triple sensor/monitor TTC-45 at 44°C on three anatomical sites (right ankle, right wrist and right elbow). AVL triple sensor TTC-45 takes 10–15 min to stabilize at each site and hence the readings are taken exactly after 15 min, when the slope of the curve becomes constant.

The $TcPO_2$ measurement is basically a polarographic determination, by means of a modified Clark-type electrode, of molecular oxygen diffusing into the skin surface. Local hyperaemia is necessary to measure PO_2 on the skin surface, which has a close relationship with change in arterial PO_2. The hyperaemic condition is achieved by heating the silver/silver chloride anode to 45°C. The PO_2 signal results from the reduction current of the platinum cathode, which is proportional to the amount of oxygen diffusing into the skin surface.

The results for smokers were compared with normal controls as nearly as possible for age and sex. Student's *t* test was used for the analysis of the data. Multivariate correlation analysis was carried out by standard statistical techniques.

The results of this study are presented in Table 2 and 3.

1. There was an increase in the whole-blood viscosity at both high and low shear rates. But changes were more significant at high shear rates ($p < 0.001$ to 0.004).
2. Increase in plasma viscosity was very significant ($p < 0.001$).
3. Red cell rigidity parameter was most significantly ($p < 0.0001$) affected as compared to other parameters.
4. Fibrinogen had the highest statistical significance among the biochemical parameters ($p < 0.001$).

(1) At ankle; (2) At wrist; (3) At elbow.

5. Red cell aggregation had a significance of $p < 0.001$.
6. Erythrocyte sedimentation rate and platelet aggregation were also elevated ($p < 0.005$).
7. Haematocrit, triglycerides and cholesterol levels were also raised, with significance values of $p < 0.005$ and $p < 0.05$, respectively.
8. Total proteins and albumin fraction were unaltered.
9. Pulse rate was higher than normal controls. In a few cases the pulse was irregular and blood pressure readings, particularly diastolic, were on the higher side of the normal.
10. Skin blood perfusion and transcutaneous oxygen tension at all the three anatomical sites were found to be low. Although skin perfusion was reduced, it was not statistically significant.

Belch *et al.*[15] have shown that smokers have elevated levels of fibrinogen ($p < 0.04$), lower plasminogen ($p < 0.02$) and higher plasma viscosity ($p < 0.003$). Just after smoking three cigarettes there was a substantial increase in platelet aggregation ($p < 0.02$), alpha2 M ($p < 0.02$) and factor VIII RAG ($p < 0.05$). A prospective study conducted by Galea and Davidson[16] and Rampling *et al.*[17] on smokers reported significant improvement in overall haemorheological and haematological variables after 2 weeks of discontinuation of smoking. Billimoria *et al.*[18] divided smokers into two subgroups based on the number of cigarettes being smoked per day (> 20 cigarettes/day: heavy smokers, and 5–15 cigarettes/day: light smokers). Heavy male smokers showed higher fasting serum turbidity, cholesterol, phospholipid, triglycerides, esterified fatty acid index of beta and pre-beta lipoprotein and reduction in clotting time compared to normal controls. In the case of the women's group, though there was increase in triglycerides, pre-beta esterified fatty acid index, longer fibrinolysis time and reduction in clotting time, no change was observed in cholesterol, beta esterified fatty acid index and fasting serum turbidity. In the case of male heavy smokers, haematocrit, haemoglobin and mean corpuscular

volume were elevated. The white cell count was very significantly raised; in particular, there was a rise in neutrophils and lymphocytes. But these changes were not observed in the women's group. In the case of light smokers, changes did not achieve statistical significance but the trend was similar. We found increase in the blood viscosity at all the shear rates considered, although changes were more significant at high shear rates than at low shear rates. This indicates prime importance of red cell rigidity among smokers. Parallel to this, rise is haematocrit also contributes to rise in blood viscosity. There was significant positive correlation (0.846) between blood viscosity and haematocrit, indicating its role in haemoconcentration. Rise in haematocrit could be a response to consistent hypoxic state among smokers. Changes at low shear rates were mainly due to increase in red cell aggregation. Increase in the red cell aggregation was mainly due to rise in fibrinogen level and plasma viscosity. Increase in plasma viscosity is attributed to rise in whole-blood viscosity as there was positive correlation between them at all the shear rates. In our study we found rise in platelet aggregation over the range 48–76%. The rise in erythrocyte sedimentation rate among smokers could be due to the presence of many charged particles released in the blood while one is smoking[19].

Among the biochemical parameters, change in triglycerides and cholesterol was significant. The increase in cholesterol has an adverse effect on red cell rheology as well as plasma viscosity. These changes were coupled with changes in microcirculatory parameters, reduction in peripheral skin blood perfusion and transcutaneous oxygen tension. Although it is premature to comment on whether these microcirculatory changes precede or follow the haemorheological changes, if we consider this in totality, it is apparent that smokers have disturbed microcirculatory flow. Reduced skin blood supply along with low oxygen partial pressure will hamper perfusion processes, resulting in accumulation of metabolites, leading to haemorheological changes. Norton and Rand[20] have reported a reduction in the surface to volume ratio in red blood cells among smokers. It is indicative of increased red cell rigidity. However, Baker *et al.*[21] found no change in the red cell deformability among smokers. Hawkins[22] in his study found that platelet aggregation can be induced at lower concentrations in smokers than in nonsmokers. The coagulation time of whole blood in smokers were significantly shorter at 0.001% level. The thromboelastograph also reflects similar results. No difference in platelet counts is indicative of qualitative changes in the functioning of platelet cells in this context. In smokers the increase in maximum tensile strength of a clot was observed by 5% compared to nonsmokers. This indicates that there is a greater risk of formation of haemostatic plugs. This could offer a probable explanation of why smokers have higher rate of cardiovascular morbidity and mortality.

The microcirculatory changes mediated through vasopressin were studied by Waeber *et al.*[24]. In their study on 20 male volunteers using laser Doppler flowmetry, reduction in blood flow was observed by induction of concomitant stimulation of vasopressin secretion.

In conclusion, blood viscosity and microcirculatory parameters should be included in routine medical check-up for early detection of silent clinical conditions associated with smoking.

Law, Ethics and HIV, Proceedings of the UNDP Intercountry Consultation. Robert A. Glick, ed. UNDP, New Delhi. 246, pp., 1993.

AIDS is big news today, disturbing and fearsome to people everywhere. The fact that most people are unaware of the potential threat for which there is no vaccine nor cure makes the problem challenging to policy planners and decision makers in the areas of health, human rights and social security. Because of the prospect of undermining social and economic development, HIV/AIDS epidemic is perceived as a development problem to be attached through available strategies of prevention and containment. Little is achieved by generating a scare in society, though the problem warrants nothing less from all concerned. Still less is accomplished by sitting back and lamenting on the catastrophe about to befall humanity, particularly in those parts of the world where poverty and backwardness have already put life in jeopardy for many people. Statesmen are worried about nuclear weapons, and their proliferation in the world. They, therefore, put nuclear non-proliferation issue as the number one item in the international agenda. They are probably unaware of the silent but sure killer developing in their backyard for which no treaty nor declaration can be an adequate response. The HIV/AIDS issue is at once a challenge and an opportunity for united action for the entire world to prevent human suffering and promote the ultimate human right to life and happiness.

If the problem is overstated, it is deliberately so done. Even educated people refuse to believe the terrible consequences of this dreaded disease. When the potential threat to human survival from the HIV/AIDS was narrated in a social gathering recently, an old lady in the neighbourhood paused and added that it might well be so because such a calamity is predicted in the scriptures several centuries ago. A feeling of helplessness and a sense of inevitability seem to be the reaction of the old and elderly. On the other hand, the younger generation refuse to believe it to be so serious and think that modern medicine does have a cure for every illness, including AIDS. The medical profession, at least in India, seems to have not taken up the issue with the attention it deserves and the media is indifferent excepting on occasions when a sensational story makes news. In this context, the initiative of the Regional Bureau for Asia and the Pacific of the United Nations Development Programme to study the legal, ethical and policy framework in different societies in the region is to be welcomed. Information is the key for intelligent policy-making. Law can succeed only when it is based on correct information as to the behavioural patterns, motivations and beliefs of people whose conduct it is supposed to influence. It is, therefore, of great advantage to the countries in the region that the volume under review has brought together a wealth of information which provides at least a base for further inquiry and research to guide policy on this vital area of public health and human rights.

The volume essentially is a collection of papers written by experts organized around issues and countries in the Asia–Pacific region. A third section addresses questions on strategies and priorities, giving policy choices in the available legal framework. The foreword by Justice Michael Kirby comprehends the objective and thrust of the whole exercise. A collective appreciation of the strengths and weaknesses of the myriad legal regimes of the region in responding to the unlimited peril of HIV/AIDS resulted in the identification of a variety of strategies varying from increased availability of condoms, safe sexual practices through family education and equal states of women in decision-making processes. More popular education and better policies on drug use, public health and prostitution are recommended by the paper writers as possible initiatives in preventive action. The object of networking in the region for dissemination of information on policies and programmes directed towards HIV/AIDS is indeed a commendable outcome insofar as not much is known about the disease and about how to counteract its spread, given the attitudes and behaviour towards sex of the people. As the editor of the volume expects, the papers should assist in defining a research agenda for the future and in assembling a practical action programme.

For a student of law, the HIV/AIDS debate raises a number of issues for interrogation. It is accepted that, in the interest of public health, individual rights can be restricted. In the present context, can we articulate the limits and limitations which can possibly be imposed on freedom and liberty? How do religious freedom and minority rights in a democratic, pluralist society get affected by public health considerations and to what extent are they constitutionally justified?

Regulating sex behaviour has been a most difficult and controversial area of law. It is common knowledge that observance of safe sexual practice is the best strategy for prevention of HIV/AIDS. To what extent can law facilitate such practices? Under what circumstances can law punish unsafe sexual behaviour? Should prostitution be prohibited, regulated or legitimized in the interest of safe sex? Can HIV-infected persons be isolated and their sexual activity controlled?

Issues are complicated in several jurisdictions in the region because of the prevalence of customary, cultural and religious practices not always conducive to safe sex approaches. Ethical and moral standards of communities are developed not necessarily on rational and scientific arguments. They are of mixed origin and followed by habit without challenge. Obsensantism, superstition and exploitative customs complicate the situation, posing serious challenges to social engineering through law.

In an incisive essay contributed by Julie Hamblin on the role of law in developing HIV/AIDS policy, three models are suggested, namely, the proscriptive model, where conduct is influenced by penal sanctions, the protective model, wherein the law tries to uphold the rights and interests of those affected or likely to be affected by HIV/AIDS through rights-sensitive legal responses; and the instrumental model, where law is a proactive instrument to advance social policies through value changes. Keeping in mind the record of criminal law, it is argued that the proscriptive model could become counterproductive. Compulsory testing and reporting with concomitant sanctions for noncompliance may impede preventive efforts. Nonetheless, the temptation for policy makers is to go for the quick and easy response of prohibition and penalization. Today, when decriminalization in drug use and in prostitution is widely canvassed, the proscriptive role of law has to be invoked

for negative prohibition rather than for positive criminalization.

Imaginatively used, law has a significant role in promoting the desirable conduct by intelligent arrangements of incentives and disincentives in a broad spectrum of activities. There are many examples of such use of law in society and the scope of similar use in the control of HIV/AIDS needs to be examined. The proactive role of law is one which requires a variety of informational input, policy coordination, monitoring, research and development. It envisages a sophisticated legal system with established institutions and standards. A law reform process should be built into the system. Interaction among different professionals, continuing education for actors in the system and adequate research and media support are necessary for law to influence social change in complex issues of human behaviour. Every society does use law in this role with varying degrees of success. Here law can well reinforce other forces of change in society. According to Julie Hamblin, the instrumental role of law to buttress other HIV/AIDS strategies is critical in the 1990s.

The papers raising these issues make interesting reading, particularly for those from outside the countries of their reference. A case study on labour legislations and labour relations from the Phillippines seeks more specific standards and guidelines from the law to compel employers to adopt more enlightened and human-rights-friendly approaches. Another case study from the same country examines the law on privacy and information in the context in HIV/AIDS and projects its potential for influencing positive behavioural change.

Family law buttressed by religious beliefs and the unequal and discriminatory status of women, particularly in family relationships, are the issues examined by participants from Malaysia and India, respectively. They bring out a variety of inadequacies in the existing law which inhibit proper awareness and positive responses to the AIDS syndrome.

The section on country papers includes ten contributions from as many countries in the region. They are a valuable source of information on the existing legal framework and to plan further action in the legal and ethical fronts. Comparative experiences from different countries are of great value to researchers and policy planners, particularly when the problem affects the entire humanity across political boundaries.

The third section, which claims to contain policy/strategy papers, is perhaps the weakest segment of the publication. Much of the ideas contained are repetitive and placement-rhetorical. The presentation of HIV epidemic as a development issue is not convincing enough. Critiquing the health care systems in the context of the demands of individual rights does not make much sense in the framework of a market-driven economy. However, a beginning is made by articulating the problem and questioning some of the established public health policies. Law has to be used, but with caution and restraint.

On the whole, UNDP Regional Project has done a great service in bringing the issues together and inviting the attention of researchers and policy makers, health administrators and human rights activists to the implications of an epidemic which may be the worst human disaster unless preventive strategies are adopted well in time. This is an issue as important as nuclear disarmament or environment protection. It deserves as much attention to world leaders and scientists as is being given to environment and nuclear arms. Perhaps the Secretary General may consider declaring the UN year for AIDS Awareness and Prevention and may take steps to convene a World Summit before the turn of the century to evolve concerted action to face the challenge.

The Collected Papers of Albert Einstein - Volume 5 - The Swiss Years: Correspondence, 1902–1914. English Translation, Princeton University Press, Princeton, New Jersey. 1995.

Well before his passing away in 1955 at the age of seventy-six, Albert Einstein's name had become a household word throughout the world. Aptly characterized as 'creator and rebel', through his work he profoundly altered forever our understanding of the natures of space and time; created a new theory of gravitation unparalleled for its beauty and significant for bringing geometry once more into the domain of science; and with Planck before him and Bohr after, opened the doors to the stunningly unfamiliar and rich quantum view of nature.

Already in 1950 Einstein had signed and sealed his last will and testament. His secretary since 1928, Helen Dukas, and his friend Otto Nathan were named joint trustees of his estate, with the latter being sole executor. Possibly due to their attitudes and perceptions of their responsibilities, the world has had to wait for almost four decades before Einstein's papers became available for open study and publication. Predictably, in the last couple of years and in tune with today's 'bare all' journalistic tendencies, there has appeared a rash of accounts 'exposing' Einstein's affairs, especially his relation to his first wife Mileva. On the scientific side, his collected works are yet to appear in final and definitive form; in contrast, those of Neils Bohr have been available now for a quarter century or so.

The book under review is the fifth volume of Einstein's collected papers, being published in English translation by Princeton University Press. It covers the Swiss years, 1902 to 1914, and is a collection of over five hundred letters written to or by Einstein. At about the beginning of this period, in early 1901, he had become a Swiss citizen. He came to Bern in February 1902 and a few months later, as all the world knows, he obtained employment in the Patent Office as 'Technical Expert, Third Class'. His father died later that year, and he married Mileva in January 1903. His sons Hans Albert and Eduard were born in 1904 and 1910 respectively. After seven years at the Patent Office, in 1909 he resigned to become Associate Professor at the University of Zurich. Soon there was a brief move to Prague, then a return to Zurich but this time as Professor at the ETH. This too was not to last very long, as an irresistible offer took him away to Berlin in early 1914. Also, towards the end of this period, the relationship with Mileva was breaking up, and he was getting very

close to his cousin Elsa Lowenthal, whom he was to marry in 1919.

In his physics, we see Einstein at the start of his career, with rare independence and boldness in his conceptions, slowly gaining recognition from his peers, until he matured into the acknowledged and unrivalled master. The period of this volume covers 1905—the 'annus mirabilis' when he sent his three epoch-making papers on Brownian motion, special relativity and the photon concept to the *Annalen der Physik*; the holding in 1911 of the first of many memorable Solvay Congresses in Brussels; and the initial insights and understanding of relativistic gravitation which culminated in 1916 in his general relativity theory.

Einstein's major correspondents in these five hundred and odd letters were his friends from youth, a few members of the family and some of the leading physicists of those times including his seniors. Such a volume has certain inevitable drawbacks as one cannot read the contents as one might read a novel or biography or a properly written account of some scientific topic. There are gaps, often an answer to a letter no longer available, so one is left guessing. Nonetheless one gains a general impression of the growth of Einstein's scientific ideas, the development of personal relationships, the steady increase in his confidence and depth of understanding and independence and strength. We also see how scientists interacted with each other in those times. We are reminded too that Einstein was not always a grey eminence with a saintly halo, but was once a young man on the threshold of life, with all the feelings natural to such an age.

Given the scale of his accomplishments, Einstein is often compared to Isaac Newton. What emerges from these letters is that Einstein had really a very easy-going nature, willing to joke with others in a light-hearted and playful manner, and no signs of malice towards anyone—all in all, a contrast to the somewhat dark, secretive and vindictive Newton. He seems to have had a balanced view of people and circumstances, and an ability in many ways to distance himself and stand apart in judging any situation. Also of course the strength to get to the heart of any scientific matter and to be concerned with the fundamentals.

On the family side, one is surprised to see not a single reference in any letter to the death of Einstein's father in October 1902. Indeed, even letters between Albert and his mother Pauline are quite rare, and he was very much aware of the strains between her and his wife Mileva. There is a 1903 letter of Einstein to Mileva, which refers to a daughter Lieserl born to them before marriage. In the early exchanges between them, one sees much affection and use of pet names, much warmth. But as the years go by, these wane. Towards the end of this volume there are many letters from Einstein to Elsa, though few replies, bringing out his dependence on and need for her company. A quite amusing letter to one Georg Meyer asks the latter to 'bear no grudge against your good wife, who did nothing wrong—a reference to an early attachment of Einstein's? All this goes to reinforce the contrast with Neils Bohr's family background—a stable and caring academic atmosphere, and a deep and cordial marriage that lasted many decades.

On the scientific side, we see Einstein's early concerns with the foundations of thermodynamics, attempting to develop them from the atomic-molecular point of view. These are generally not as well known as Boltzmann's and Gibbs' endeavours; they remind us sharply that there was a time when the reality of atoms was suspect, and that too not so long ago. We also see how he was simultaneously grappling with diverse foundational problems—thermodynamics, electrodynamics, nature of space–time, nature of radiation, the quantum puzzle—none of which would 'leave him alone'. It was a ceaseless struggle to penetrate the secrets of nature, on many fronts, not always only the deep and beautiful but also often the most practical. His interests in problems of chemistry, bringing out again the molecular basis of matter, were recurring. As a young man, his letters to both Lorentz and Sommerfeld show the greatest of respect. Indeed we can say he regarded the former as a kind of father-figure. Describing Lorentz's handling of the sessions at the first Solvay Congress, Einstein says 'Lorentz chaired the conference with incomparable tact and unbelievable virtuosity'; and elsewhere calls him 'a work of art'. In an early letter to Sommerfeld, in 1908, Einstein expresses the wish that he would like to 'perfect my knowledge of mathematical physics' by sitting in on Sommerfeld's lectures. The early letters to Stark and Lenard are also very respectful; but thereafter references to the latter are quite disparaging. These two were later to be in the forefront of the antisemitic attacks on Einstein.

Many of the letters are detailed exchanges of views on scientific problems in a leisurely and open manner that in today's competitive atmosphere are practically unthinkable. The struggle with the photon idea, and Lorentz's detailed analysis and criticism of Einstein's conceptions, are most revealing, though with today's understanding they may seem not very relevant. One misses however, and sadly, the three 1905 letters of submission to the *Annalen der Physik*. On the professional side, one is treated to the hilarious game of musical chairs among the German-speaking universities of the day—a new occupant of a chair at one place immediately waiting to 'receive a call' to move to a better place. During Einstein's brief tenure at Prague, he expressed himself quite frankly against the bureaucracy, stifling traditions and poor quality of students of the place. The several efforts to lure Einstein to Holland, at times involving Lorentz, are part of this drama of constant movement.

Towards the end of this volume comes the phase when Einstein was working feverishly, sided by Marcel Grossmann, to create his new theory of gravitation—the many insights, false leads, the realization that mathematical structure has a great role to play alongside physical reasoning. And on the personal side, the growing relationship with Elsa. To the reader too, hopefully, should come the realization that these letters, and especially the earlier ones which were presumably written with no inkling that they would one day achieve archival value, ought to be read with consideration and a sense of humility.

SPECIAL DRIVE FOR RECRUITMENT OF SC/ST CANDIDATES

Applications in the following format are invited from SC/ST candidates only for recruitment to the following reserved posts:

1. Name in full (in block letters); 2. Mailing address; 3. Sex; 4. Date of birth and age as on 1. 1. 1995 (documentary evidence to be enclosed); 5. Father's name; 6. Whether belongs to SC/ST (documentary evidence to be enclosed); 7. Nationality; 8. Educational qualifications (in chronological order from matriculation onwards) (enclose a separate sheet, duly authenticated by your signatures) documentary evidence is to be enclosed; 9. Experience (if any) with field of specialization 10. Employment record (separate sheet to be enclosed); 11. Whether a Govt. servant?; 12. Give names and addresses of two referees not related to you; 13. List of enclosures.

1. SENIOR SCIENTIFIC OFFICER GRADE-II :

Three posts (one post reserved for SC and two posts reserved for ST candidates)

Scale of pay	:	Rs. 2200–75–2800–EB–100–4000.
Age limit	:	35 years or below as on 1. 1. 1995
Qualifications	:	*Essential*: (i) A good Master's degree or equivalent in Meteorology, Physics, Mathematics, Applied Mathematics, Statistics, Applied Physics, Geophysics or Electronics or BE/B Tech/M Tech (Electronics/ Electrical Engineering) degree. (ii) About 3 years research experience (as evidenced by published papers). *Desirable*: Knowledge of numerical techniques as applied to atmospheric numerical models/statistical methods and computer programming/data base management/systems programming.

2. JUNIOR SCIENTIFIC OFFICER :

One post (Reserved for ST candidate)

Scale of pay	:	Rs 2000–60–2300–EB–75–3200–100–3500
Age limit	:	30 years or below as on 1. 1. 1995
Qualifications	:	*Essential*: A good master's degree or equivalent in Meteorology, Physics, Mathematics, Applied mathematics, Statistics, Applied physics, Geophysics or Electronics or BE/ B Tech./ M Tech. (Electronics/ Electrical Engineering) degree. *Desirable*: Knowledge of numerical techniques applied to atmospheric numerical models/Statistical

methods and computer programming/data base management/systems programming.

3. SECTION OFFICER :

One post (Reserved for ST candidate)

Scale of pay : Rs 2000–60–2300–EB–75–3200–100–3500

Age limit : 35 years or below as on 1. 1. 1995

Qualifications : *Essential*: (i) Bachelor's degree, (ii) About 5 years experience in Accounts/Administration/Purchase and Stores work in a Scientific/Technical/Govt./ Semi-Govt. organization of which at least 3 years should be in a supervisory grade.

4. JUNIOR TECHNICAL ASSISTANT (Computer)

One post (Reserved for ST candidate)

Scale of pay : Rs 1320–30–1560–EB–40–2040

Age limit : Minimum 20 years and maximum 25 years as on 1. 1. 1995

Qualifications : *Essential*: A degree in Science or a diploma in Engineering or a National Apprenticeship certificate or an ITI Certificate (after matriculation) or a matriculation with minimum 3 years experience in Computer Programming.

Desirable: Knowledge of PC, software packages like DBASE, WORDSTAR and FORTRAN Computer programming.

5. STENOGRAPHER GRADE-III :

One post (Reserved for ST candidate)

Scale of pay : Rs 1200–30–1560–EB–40–2040

Age limit : 18–25 years as on 1. 1. 1995

Qualifications : *Essential*: SSC or equivalent with minimum speed of 40 wpm in English typing and 100 wpm in English shorthand

Desirable: Good command over English and knowledge of typing on Wordstar.

The posts carry other allowances admissible to Central Govt employees stationed at Pune.

Upper age limit is relaxable by 5 years for candidates as per rules for ex-servicemen and physically handicapped persons. No age limit for the employees of IITM and Govt servants.

Last date for receipt of application is 29 December 1995.

Candidates already employed in Government/Semi-Government organizations/Public Sector Undertakings should apply through proper channel.

Special Drive Advt. No. Est. 4/95.

INDIAN COUNCIL OF AGRICULTURAL RESEARCH

The Indian Council of Agricultural Research, New Delhi announces the following existing and new Awards.

Rafi Ahmed Kidwai Awards, 1993–95

All research workers above 35 years of age engaged in the research in the field of agriculture, animal husbandry and allied sciences in India shall be eligible for the Award. Nine awards of Rs 100,000 each are to be given once in three years for the work done during the preceding three years of the period of the award.

Fakhruddin Ali Ahmed Awards, 1994–95

All research workers engaged in research in agriculture, animal husbandry, fisheries and allied sciences in tribal areas (tribal areas for this purpose are those notified by the Ministry of Home Affairs, Govt of India) will be eligible for applying for the Award. Two prizes of Rs 50,000 each are to be given once in two years for the work done during the preceding two years of the period of the award.

Vasant Rao Naik Award, 1995

All scientists or extension workers who have made outstanding contribution in the areas of water conservation and dryland farming in India shall be eligible for the award. One Award of Rs 100,000 is to be given annually, for the work done during the preceding five years.

Outstanding Teachers Awards, 1994–95

All staff members engaged in undergraduate or postgraduate teaching for at least 10 years in deemed universities, ICAR Institutes and State Agricultural Universities shall be eligible for the award. Eight awards of Rs 20,000 are to be given once in two years.

Outstanding Women Agricultural Scientist Award, 1995

All women scientists working at the Institutions under the ICAR system including State Agricultural Universities are eligible for the award. One award of Rs 25,000 to be given annually for the significant contributions made during her career as an agricultural scientist.

The application form for the above awards may be obtained from Dr R. C. Maheshwari, Asst Director General (CSC), ICAR, Krishi Bhawan, Dr Rajendra Prasad Road, New Delhi 110 001, on or before 15.2.1996 by sending a self-addressed one rupee stamped envelope. Six copies of the application may be forwarded by the Head of the Institution/Directors of Institutes/State Dept of Agriculture/Horticulture/Animal Science/Fisheries and Vice-Chancellors of State Agricultural Universities. The last date of submission of applications for these awards is 15 March 1996. The last date for candidates in the Andaman and Nicobar Islands, Lakshadweep States, Union Territory in the North Eastern Region, Ladakh Division of J&K State and Sikkim is 31 March 1996.

International Conference on

EUKARYOTIC EXPRESSION VECTOR SYSTEMS: BIOLOGY AND APPLICATIONS

February 4–8, 1996, New Delhi, India

Organizers: S. E. Hasnain, National Institute of Immunology, New Delhi; N. Khanna, International Centre for Genetic Engineering & Biotechnology, New Delhi; M. D. Summers, Texas A&M University, College Station (Chair).

The meeting will discuss state of the art in baculovirus, mammalian viruses, yeast, *Pichia* and other heterologous gene expression systems. Advancements in medical and veterinary therapeutics, biotech drug targets, diagnostics, vaccines and gene therapy, biopesticides, fermentation and downstream processing will be presented. The format will consist of invited lectures, short talks and poster sessions. The proceedings, after peer review, will appear in GENE.

Speakers: Mike Betenbaugh, Johns Hopkins University; David Bishop, IOV; Samir Brahmachari, Indian Institute of Science; Dipankar Chatterjee, Centre for Cellular & Molecular Biology; Asis Datta, JNU; Reiner Gentz, Human Genome Sciences, Inc.; K. P. Gopinathan, Indian Institute of Science; Seyed Hasnain, NII; Cornelis P. Hollenberg, Institut fur Mikrobiologei; Michael Karin, UC-San Diego; Navin Khanna, ICGEB; Jaspal Khillan, Thomas Jefferson University; Peter Liljestrom, Karolinska Institut; Susumu Maeda, UC-Davis; G. Padmanaban, Indian Institute of Science; Polly Roy, University of Oxford; Walter Schmidt, Research Institute for Molecular Pathology; Gale Smith, MicroGeneSys; Arun Srivastava, Indiana University; Koti Srikrishna, Marion Merrel Dow Inc.; Max Summers, TAMU; Waclaw Szybalski, UW-Madison; Inder Verma, Salk Institute; Just Vlak, Agricultural University; J. Wild, UW-Madison.

Fee of US$ 300.00 (Rs 3,000.00 for participants from India) will cover registration, lunch/dinner during the meeting. A few registration waivers available for deserving candidates. Send abstracts (15 × 20 cm) and brief CV before **December 22, 1995** to **Dr S. E. Hasnain, National Institute of Immunology, Aruna Asaf Ali Marg, New Delhi 110 067, India**; Tel: (91-11) 6863004 to 6863009, 6863011 to 6863013, 6862281; Fax; (91-11) 6862125, 6867626, 662608; Email: ehtesham@nii.ernet.in

Random numbers

The notion of a 'random number' is of interest to scientists in a wide variety of disciplines, and is also the subject of philosophical speculations. This issue carries an article by K. R. Parthasarathy (**page 904**), an internationally renowned expert in probability theory, discussing some properties of random numbers.

It has been observed that population sizes of certain animals show peaks every 3 years, on the average. Parthasarathy's article starts with a quotation from C. R. Rao, which outlines a simple probabilistic explanation for this phenomenon. The article goes on to examine in more detail the following question; if $\xi_1, \xi_2, \ldots$ is a sequence of random numbers uniformly distributed in the unit interval [0, 1], what is the average length of time between successive 'k-peaks'? Here, ξ_n is a k-peak if it is greater than its k immediate predecessors or successors (that is, ξ_n is greater than any of $\xi_{n-k}, \xi_{n-k-1}, \ldots, \xi_{n-1}, \xi_{n+1}, \xi_{n+2}, \ldots, \xi_{n+k}$). The answer is shown to be $2k+1$, which for peaks (i.e. if $k=1$) reduces to 3, as pointed out by C. R. Rao. This is a consequence of an analysis carried out using the individual ergodic theorem of Birkhoff, and the Central Limit Theorem. The analysis also yields large sample tests to check if a given sequence of numbers is random.

Sample compositional model of the earth's inner core

The earth's core is the region extending from 2890 km to the centre at 6371 km. Several models exist to explain the composition of the earth's interior which is not available for direct observation but has to be inferred from a variety of disciplines. The outer part of the core is considered to be in liquid form since it does not transmit shear type of earthquake waves. The inner core is believed to be solid with a density of about 13.

It is commonly assumed that the core consists of iron and nickel, much the same composition as the meteorites. Various types of evidence point to iron being the major component of the core. Saxena (**page 914**) reviews some of the new techniques of heating solids with a laser at ultra high pressures in a diamond anvil. The new data lend support to a simple model of the core which is identical to that of iron and stony meteorites, the debris derived from differentiated broken-up planetary bodies. The density of such material seems to compare well with the seismic density. The reason why the outer core is in liquid form is explained to be the result of the phase transformation in iron and its melting behaviour.

VASVIK RESEARCH AWARDS

1995

OBJECTIVES

We have instituted seven annual VASVIK Industrial Research Awards, each of Rs. 25,000/-, a citation and a gold medal to be awarded to an individual or group of individuals, who, in the opinion of our Board of Advisers, have made outstanding contribution to the advancement of science and technology leading directly to national prosperity in India.

SCOPE

Consideration will be given to achievements in design or any production techniques or methods, particularly with regard to their impact on industrial and economic growth, import substitution, saving of foreign exchange, cost reduction, etc. Achievements within the past 10 years will be given priority, if they are of value to manufacturing industries, including the process of agricultural production.

FIELDS

The awards will be given to Indian citizens for research in each of the following fields:

a) Agricultural Sciences and Technology
b) Biological Sciences and Technology
c) Chemical Sciences and Technology
d) Electrical Sciences and Technology
e) Electronic Sciences and Technology
f) Material Sciences and Technology
g) Mechanical Sciences and Technology

SPECIAL AWARD FOR WOMEN SCIENTISTS

VASVIK has also instituted a special award solely for women scientists, known as SMT. CHANDABEN MOHANBHAI PATEL VASVIK AWARD FOR WOMEN SCIENTISTS, carrying a cash prize of Rs. 25,000/-, a citation and a gold medal, to recognise and encourage women's participation in science and technology leading to national prosperity.

NOMINATIONS

Applications/Nominations for the year 1995 may please be submitted in prescribed format before 30.4.1996

Hemp in the manufacture of paper

Hemp – *Cannabis sativa* (often called Indian hemp) – has been cultivated in India for centuries, especially in regions where rivers flood their banks, because the plant holds the soil and prevents soil erosion. The plant produces strong pliable fibres (the word 'hemp' is used for both the plant and the fibres). The fibres are extremely strong and have been used since antiquity for weaving sail cloth, and for making large diameter ropes used in ships etc.

The male plant bears flowers in axillary racemes and dies soon after pollination has taken place. The female plant bears flowers in crowded spikes and dies after the seeds mature. Plants of both sexes are used for fibre. The hemp stem is hollow and has an inner fibrous bark. While strong coarse fibres are obtained from mature plants, soft ones obtained from hemp harvested at pollination are used for making cloth of fine texture. The fibres from the bark are used to make a great variety of textile products.

Hemp contains the psychoactive drug tetrahydrocannabinol, popularly known as marijuana. Narcotics like charas, ganja, etc. have been extracted in India from the hemp plant for centuries.

More recently, material scientists in India have considered hemp fibres as ideal for making fibre-reinforced plastic (FRP) composites because of the strength and length of the fibres. Further, hemp fibres contain a fair proportion of amorphous silica, making them behave almost like glass fibres except that hemp fibres are much tougher. Hemp fibres add strength and stiffness to plastic products and can be used to substitute glass (G) in GFRP products. Attempts to use treated hemp fibre to substitute partially asbestos in 'asbestos cement sheets' (used for roofing) have been fairly successful.

Now comes the news (*Environmental Health Perspective*, 1995, **103**, 893–894) that hemp is one of the best fibre sources for paper and therefore could be used in its manufacture. It is much better than jute, kenaf, flax or bagasse. In recent experiments, high-quality bond paper has been produced with 10% hemp together with recycled paper pulp. Lower grade but strong paper has also been produced for copiers. Hemp paper is considered environmentally very good as no chlorine bleach or acid treatment is necessary. Cultivating hemp, it is said, will save trees and minimize pesticide demands. Since cultivating the marijuana plant in the US is illegal, hemp pulp is being imported into the US from China and Hungary. Attempts are also being made to use genetic engineering to produce hemp not containing the drug tetrahydrocannabinol. There are some negative aspects too – Hemp plants require nitrogenous fertilizers; so hemp fibres may be much costlier compared to other materials like wood, bamboo, etc. used in paper manufacture. One does not know how the high silica content in this fibre will affect the paper-making machines.

S. Ramaseshan, Raman Research Institute, Bangalore

CORRESPONDENCE

Nurturing young scientists

It is said in common scientific parlance that best scientific contributions come from 'young' researchers. More often than not, Nobel laureates are rewarded for their work that was performed in their mid-thirties. Younger researchers are, hence, a breed that need to be nurtured with care all around the world and India, in particular. Given the right impetus, support, and direction this flock of assertive dedicated individuals can perform wonders. This is especially important in our changed times when India needs to compete and succeed globally on all frontiers of technology.

Much to the chagrin of young investigators, however, the research environment in our country is forsakenly taken to be rather dull and sleepy. A project proposal to government agencies, in general, takes anywhere from six months to more than a year for appraisal, to which six more months are to be added for money disbursal. The young scientist

proposal is expected to take much less; yet, invariably it consumes a lot of time. In these days of rapid technological change a loss of one year in research activity is like unquestionably accepting the forced directive of being condemned to technological backwardness, if not obsolesence. In much the same token, inefficient and inadequate financial support produces equivalent result. More important is the associated danger of a young scientist losing the self-confidence and the drive to compete internationally when saddled with these time and money problems at such an early stage of his career. If the nation needs technology to be delivered for social benefits, it is imperative that all researchers, and especially the younger ones, are supported duly. A nation is what its young people are and what they want to be.

The Department of Science and Technology operates a scheme for initial support of young scientists (below 35 years) to perform research. The basic idea is to provide some quick seed money required to establish a new laboratory/facility and allow the young investigator to take roots. At the present time this scheme can at best provide an amount of Rs 3 lakhs for a two-year period. At the earliest, the administrative machinery at DST can initiate the operation of a project under this scheme in a minimum of six months time; most projects usually take more. The *modus operandi* of initiating a project includes securing at least two referee reports. Recently, the Board of Research in Nuclear Sciences has come up with a similar scheme having a Rs 5 lakhs financial cap. It is anticipated that a BRNS young scientist project will take much shorter time to initiate.

The present manner of administering young scientist proposals is ineffective. The amount of time taken in processing the applications is much too large; money disbursal is evidently belated. I present some additions and modifications to the present set-up to help the young researchers' fraternity. Following are my point-wise recommendations with a brief discussion of appropriate rationale:

- *India should* **not** *have multiple Young Scientist schemes running in different government agencies.* If the goal of each scheme is the same, we need not have one scheme competing with the other. One manager is usually better than multiple managers—why duplicate effort?
- *The administration/management of young scientist proposals be taken over by previous Young Scientists.* A group of previous young scientists, who have experienced the process earlier, be nominated for handling the research proposals. The rationale is that these scientists will better appreciate the needs of their cadre and speeden-up the entire process. Governmental delays regarding appraisals, cataloging, communication, etc. will be reduced drastically. In addition, the applications be treated in the same manner as scientific papers to expedite the process. The process of project appraisal will essentially remain the same, however, communication with established scientists will be improved. Younger investigators at premier institutions such as Tata Institute of Fundamental Research, Indian Institute of Science, Indian Institute of Technology, etc., may be appointed for handling these proposals.
- *The time required to process a Young Scientist proposal be reduced to a maximum of three months.* This should include the review process, the decision on whether to fund, and communicating the final decision.
- *The recommendations of the reviewers be followed in budgetary allocation.* The young investigator be intimated of the budgetary allocation and asked for his confirmation or appeal. The approval of the young investigator on budgetary aspects should be deemed necessary for the final approval before the project is submitted to the finance manager for money remittance.
- *A finance manager(s) be appointed aside from the proposals management group who will handle the money disbursal and money utilization part of the proposal.* Ideally he should be a young scientist. If not, a cell in one of government bodies be designated to solely handle this function.
- *Money should be sent to the concerned investigator within two months of the approval of the proposal.* It is imperative that this function is given utmost importance. Time saved is money gained. If a cell or manager is identified with this function only, drastic reduction in time required may be achieved.
- *The maximum financial support be set to Rs 10 lakhs for a two-year period.* Out of this an investigator can claim up to 80% for the first year. This will allow greater latitude in research organization of the project and in management of facilities. A young investigator needs greater financial support earlier in his career than later; more so when he is setting up his laboratory.
- *In the first 3 years of initiating research activities, a young scientist may be allowed to work with two Young Scientist projects subject to the condition that he/she has no funding from any other source.* The rationale for this is the following: Very often in the initial stages one is not certain about success in a particular area and wants to explore more before committing himself/herself to a certain direction. In addition, better laboratory funding will allow greater flexibility in choosing advanced laboratory equipment that may be necessary for research.
- *The feasibility of processing applications before the actual employment should be maintained and encouraged.*
- *Under special circumstances a young scientist be allowed to present his proposal before the review committee without submission before-hand to expedite his application.* Some unforeseen events may delay the submission of applications. If appropriately justified, an application be considered before a meeting of the review committee for possible funding. This will help save more than a year for the young applicant.

The basic goal in all the above suggestions is to reduce the time required to initiate a project. If the process is considerably improved it may serve as an incentive for young researchers abroad to return to their motherland and do some good. A very encouraging thought is the reduction in brain-drain.

Early research in India on primate tool using

Tool using by free ranging chimpanzees in East and West Africa is now well known to ethnologists. One of the earliest examples of the study of tool using by a captive chimp originates from the Teneriffe island research station[1]. This was followed by the famous work of Koehler[2] in 1915 and later summed up[3] in 1925.

We have recently come across a relatively obscure paper in which, as early as in 1902, tool using by a captive orang at Alipore Zoo, Calcutta was described by Sanyal[4], the first Indian Superintendent of that zoo. The orang at first tried, ineffectually, to reach the remnants of a proboscis monkey's breakfast in the adjoining cage. Then he collected straws from his sleeping quarters, fashioned a rough rope out of these. With the help of this rope he succeeded in pushing the tin of breakfast within reach.

More on microbiology

R. Maheshwari's commentary 'Whither microbiology' (*Curr. Sci.*, 1995, **69**, 401–406) was an eye-opener even for a dyed-in-the-wool biologist like me. How many younger biologists would know without the benefit of this article that a study of microbiology will show that life is an autocatalytic process, that the principle of natural selection can be understood by raising enrichment cultures, that we can understand the unity of biochemistry, regulatory mechanisms, existence of permease, learn that bacteria invented photosynthesis and that plant chloroplasts are merely domesticated cyanobacteria, and that the study of *Neurospora crassa* led to the formulation of one-gene-one-enzyme hypothesis which revolutionized biology? Maheshwari has presented the case for the study of microbiology very persuasively and eloquently. To further strengthen Maheshwari's brief I quote the following from a recent article[1]: 'Recent analyses of phylogenetic frameworks have confirmed that the filamentous fungi share the closest evolutionary relationship to the Animalia of any non-animal group. As model systems for understanding biochemical genetics and gene regulation, the fungi have been particularly useful. Well-known examples include cracking the cell cycle using genetics and molecular biology, analysis of the mechanism of intracellular signaling via heterotrimeric G-proteins, cell type – specificity determination (all in the yeasts *Saccharomyces* and *Schizosaccharomyces*), and developmental patterning of growth habit as in the slime mould *Dictyostelium*. The best molecularly studied microbial clock system, and one of the best understood circadian systems in any context, is that of the ascomycete fungus *Neurospora crassa*, in which a circadian biological clock controls several aspects of growth and development. There is much reason to believe that the *Neurospora* clock system (input, mechanism and output) will be the first complete system to be resolved at the molecular level.'

Microbiology is nearly the whole of biology in a microcosm. Yet as C. Woese observes (cited by Maheshwari), 'University microbiology departments are withering. . . . Microbiologists are afraid to teach real microbiology anymore.' At the University of Wales, what was once a flourishing and world famous Department of Microbiology, headed by David Lloyd, was merged into rest of biology. I fervently hope that Maheshwari's stirring article will draw the attention of students who are on the threshold of choosing some kind of biology. In a lighter vein, in my ignorance I had all along believed that extremophiles, were scientists who went to extremes of maintaining that their kind of science alone mattered.

Karnatak music

I would like to point out that certain statements made in the article are not correct ('The structure of *Raga* music' by R. Ramanna, *Curr. Sci.*, 1995, **68**, 897–916). Ramanna states that a change of tonic (*Shruti*) in a piece of Carnatic music is strictly forbidden. This certainly is not true and there are musicians, especially the most skilled and imaginative, who use tonic shifts (*Shruti Bhedam*) routinely in their concerts. Examples can be quoted from numerous concerts of Balamurali Krishna and late Maharajapuram Santhanam and many others. This is done even in Carnatic instrumental music concerts. What is done is not a shift of the tuning of the *Tanpura*, but stressing the new *Sa*, which is actually any of the notes of the main *raga*, sufficiently to shift the mental tonic of the listener. It is also important to include the specific ornamentation of the derived *raga* as correct *gamakas* (which are in general different from the *gamakas* in the original *raga*) to get the desired effect. Simple examples are singing *ragas* like *Hindolam* and *Madhyamavati* from *Mohanam*.

A mere shift of the tonic without including the correct *gamakas* to change *ragas* in Carnatic music is not practical except for those *ragas* in which the *gamakas* are simple, essentially those that could be played on a harmonium or any keyboard instrument, and even there the effect is momentary, in those passages where even the *gamakas* have some similarity. This aspect cannot be seen in the written notations where any consistent mapping which preserves intervals more or less accurately looks viable. However, there are rare situations where the listener may hear a *raga* which is different from what the singer sings! This happens because the actual tuning of the *tanpura* is on notes *Sa*, *Pa* and *Sa*, whereas what the listener locks on to is *Pa* as his *Sa* and then the *Sa* as his *Ma* – a tonal shift from *Sa* to *Pa* in the drone itself. Then what he will perceive would be the inverted *raga* (in the sense of *raga* generated with the first inverted *shruti* chord). This happens in those situations where the listener is very familiar with the inverted *raga* and not the actual *raga* being sung. (I have heard it only in Hindustani music.)

Another important and controversial aspect which is touched upon (but elaborated only in the book) is the question of harmony in Indian music. R. Srinivasan in his review in the same issue has mentioned some of the practical difficulties in incorporating harmony while rendering Carnatic *ragas*. I merely want to stress the fact that harmony based on triads would be possible only in the obvious cases in which the *raga* has straightforward rendering without too many dynamical *gamakas* (roughly defined as modulations which blur the note in frequency all the way to the neighbouring notes, while stressing the main note itself. For example, many of the notes in *Todi*, combinations of *Ma*, *Pa* and *Dha* in *Kalyani*, *Panthuvarali* and derivatives, etc.) *Todi* would actually be very difficult in this respect with so many dynamical *gamakas* with the notes defined in a very impressionist way. But there are also many examples in which Indian musicians have tried out harmony with good success in *ragas* which do not depend strongly on dynamic *gamakas* (e.g. parts of *Mohanam* and many pentatonic *ragas*). There is a popular LP record by Ramani and his students on flute where many harmonized passages are played very skillfully, for different *ragas*. Harmony has been tried out many times in fusion music with a good Indian music component, and two-string harmony (may not really classify as harmony) has been tried by L. Shankar on some occasions (by recording twice over, playing his double violin) with pleasing effects.

There are statements in the beginning of the article which seem to suggest that only very recently Carnatic music has come out of courts into concert halls and that transformation to hi-fi era has not taken place in India. This obviously cannot be right. In fact, everything in hi-fi including Dolby technology, CDs, good acoustics, etc., are all incorporated already in many prominent recording studios as well as concert halls dealing with Indian music. So the justification that the article aims to educate technologists and scientists on aspects which might help in this technology revolution is misplaced, and after reading the article I also felt that it really does not contribute in this aspect even if there was a need.

The listing of the historical events of importance to Carnatic music (Appendix I) includes the name of Swati Tirunal, mentioned as a *Veena* expert and not as a composer! Is it a slip or taking sides in the well-known controversy?

While introducing Ramanna's article, the editor had commented that 'probably, many scientists may feel that it is not an appropriate subject for *Current Science*'. Many scientists would not really have any objection to publishing an article on music when it pertains to a scientific analysis or study of scientific aspects of music. In fact, some of the greatest of physicists have spent considerable time on musical acoustics and related theory. What was disappointing in the article was the way irrelevant information was included as transcripts of all the *Melakarta ragas* in western notation. This straightforward mapping, once the notation is established, should have been left as 'exercise' if anybody was interested in generating the full list.

C. S. UNNIKRISHNAN

Gravitation Experiments Group,
Tata Institute of Fundamental Research,
Homi Bhabha Road,
Bombay 400 005, India

Raja Ramanna's article fails to communicate and is thoroughly misleading.

In Part I of the article, an unsuccessful attempt is made to explain the notation used in Western music. As I could not follow it and as I have no knowledge of it myself, I refrain from commenting on what is presented in terms of that notation. As regards the rest of Part I, I say, without reservation, that it does not convey anything to the reader. In Part II of the article, there is a description of what the author considers to be the salient features of a typical Karnatak music concert. When one reads through it, one is amazed by its divergence from reality. For instance, mention is made of flutists playing accompaniment to vocal musicians in Karnatak music concerts. I regularly go to music concerts and, on the average, I have attended fifteen to

twenty concerts per year during the last fifty years and more. Not once have I found a flutist accompanying a vocalist.

Coming to percussion instruments played in Karnatak music concerts, mention is first made of *Tabla* which is seldom used in Karnatak music, and of morching which is rarely used. But the more commonly used *Ghata* and *Kanjira* do not find a mention anywhere.

While dealing with *alapana* it is stated that 'more often than not, the percussion instruments are silent during *alapana* as it does not always have a *tala* structure'. It means that *alapana* **has** sometimes a '*tala* structure', and on such occasions, percussion instruments **are** played. This is ludicrous, to say the least. An incorrect statement is also made about *tani avarthanam*: 'It may or may not be supported by other instrumentalists'. What sort of *tani avarthanam* is it if it 'is supported' by a non-percussion instrumentalist?

'After completing the "statement" of *pallavi* and *anupallavi*,' according to the author, 'the main musician takes on elaboration of the two themes in which new forces are brought in, such as *Kalpana swaras*'. *Kalpana swaras* being 'new forces' used to 'elaborate' *pallavi* is just absurd. Further, 'once *pallavi* and *anupallavi* is elaborated, there is a great degree of freedom for the performer for further elaboration swara-wise and tala-wise'. Statements of this sort which challenge our capacity for comprehension are abundant in the article.

'Two *ragas* with identical *Arohana* and *Avarohana* and derived from the same *Janya Mela* may yet differ from each other', says the author. Pray, what is *Janya Mela*? It is common knowledge that the 72 *Melakarthas* of Indian music are described as 'Sampurna' *ragas* because each of them have all the seven *swaras* in the order of their frequencies both in *Arohana* and *Avarohana*. They can also be called *Janaka ragas* because all the other *ragas* are derived from them. The derived *ragas* are *Janya ragas*. From this it is evident that *Janya Mela* is a contradiction in terms and so is meaningless. The context, however, suggests that *Melakartha* is meant and not *Janya Mela*.

As an instance of the above statement *Arabhi* and *Sama* are mentioned as two *ragas* with identical *Arohana* and *Avarohana* and derived from the same *Melakartha*. It is just not true. *Arabhi* is a derivative of *Dheerashankarabharana* and *Sama* of *Harikambhoji*. Their *Arohana* and *Avarohana* are also different.

J. R. LAKSHMANA RAO

'Maithri', XII Main,
Saraswatipura
Mysore 570 009, India

Raja Ramanna replies

I do not know the status of Lakshmana Rao as a musician and therefore if he is disappointed and thinks that there is nothing in my article, it cannot be quite correct because many of the things I have mentioned are based on well-known books on Karnatic music.

It is a pity, as Rao himself says that he does not know staff notations and therefore is unable to understand the comments made using these notations, and yet says that there is nothing in them. The article is written to make it comprehensible to the practitioners and scholars of western music as well as Indian counterparts. It has been necessary to do it through staff notation. Perhaps, the best thing for him to do, I feel, is to learn staff notation and then make his comments. A. M. Chinnasamy Mudaliar (1895), P. Sambamurthy and H. P. Krishna Rao of Mysore, etc. knew western notation and used it.

About the other points. The term Karnatic music concert has been used in a broad sense. In the music team of a Bharata Natyam performance, for instance, one can see the *Flute* functioning as a support to the vocalist. According to some old timers, before the advent of the *Violin*, *Veena* and or the *Flute* were the supporting instruments in any vocal recital. Many old timers in Mysore city are familiar with the flutist M. Venkatesa Iyengar (father of Doreswamy Iyengar) supporting Venkatagiriyappa in the *Veena* recitals. In recent times M. Balamuralikrishna has given many concerts with *Flute* support.

Regarding the use of *Tabla* in Karnatic music, any old timer in Mysore city will vouchsafe the fact that it was the *Tabla* (not *Mrudangam*) which was the accompanying talavadya in the music concerts before the *Mrudangam* appeared on the scene in the 1920s. It was similar in Bangalore city. About the absence of mention of *Ghatam*, *Khanjira* the relevant sentence in my article reads 'on his right side are placed percussion instruments like the *Tabla*, *Mrudangam*, *Morching* (Jews Harp), etc., covering other instruments instead of their detailed enumeration.'

About the *alapana*, Rao has laid emphasis on words 'more often than not' and draws his own sarcastic conclusion 'as if the *alapana* has some times a *tala* structure'. Here again, the use of the words *alapana* and *tala* are in a broader sense. Otherwise, how can one classify the *alapana* performed by nagaswaram where a person maintains a beat on the cymbals while the tavil also joins. I have had discussions with no less a person than Bangalore K. Venkataram, Director of the Percussive Arts Centre, Bangalore, about the *tala* structure in *alapana*. In fact, it was he who has suggested to me to include this particular aspect in my article. *Janya* instead of *Janaka Mela* is a typographical error.

Concerning other comments, answers can be found in Sambamurthy's volumes.

Too many hepatoprotective drugs and a little hepatoprotection

This is in response to the Research Communication entitled 'Hepatoprotection by *Phyllanthus amarus* and *Phyllanthus debilis* in CCl_4-induced liver dysfunction' (R. T. Sane *et al.*, *Curr. Sci.*, 1995, **68**, 1243–1246) which describes the 'effectiveness' of *P. debilis* and *P. amarus* as hepatoprotective agents. The data are not presented properly and the conclusions drawn from them are partly misleading.

To evaluate hepatoprotection the data for CCl_4 + *P. amarus*-treated groups have to be compared with CCl_4-control group and not with normal control, and the statistical significance has to be determined between these groups. This has not been done. If there is complete hepatoprotection in CCl_4 + *P. debilis*- or *P. amarus*-treated groups, the values for serum enzymes and liver RNA shown in Tables 1 and 2 should not differ significantly between normal control group and CCl_4 + herbal drug-treated groups.

In Table 2, values for liver DNA and RNA are given. The levels of RNA decreased in the liver of CCl_4-treated animals compared to normal control. The RNA value for *P. amarus*-treated group (CCl_4 + *P. amarus*) is not statistically (significantly) different from that for CCl_4-control group. Furthermore, Table 2 has errors. All RNA values including the normal control value are marked with asterisks to indicate the level of significance. The SD for normal control group is 10.56 whereas that for group II is given as 0.7284. This is highly unlikely.

We have calculated the level of hepatoprotection in the herbal drug-treated groups based on the values given in Tables 1 and 2 for serum enzymes and liver RNA and presented in Table A. In the case of *P. amarus*, out of 3 serum marker enzymes studied, only GPT activity shows hepatoprotection (63%). The level of alkaline phosphatase activity does not show any protection. GOT activity shows a marginal effect (36%). Further, CCl_4-induced decrease in liver RNA content was not significantly influenced by *P. amarus* treatment. With these observations it should not be concluded that *P. amarus* is effective as a hepatoprotective agent. A good hepatoprotective agent must influence almost all the relevant biochemical parameters more or less uniformly. If not, a plant drug control group has to be included to find whether the plant drug influences any specific parameters in normal rats.

In *P. debilis*-treated animals some hepatoprotection is seen. Even in this case, GOT and alkaline phosphatase activities show only around 50% protection and liver RNA level shows only 28% protection. The normal recovery from damage without herbal drug treatment in three more days (six days after CCl_4 treatment) is far better than *P. debilis* treatment for three days. As compared to the values in CCl_4-control on day 3, on day 6 the recovery from damage in serum enzymes and RNA is 60–80%.

Although the authors compared all the biochemical parameters with those of the normal control rats, the normal control rat liver histology figure is not given. It is better to show that, at least, for the benefit of those readers who are not familiar with liver histology. Some variations in the degree of histopathological changes can be seen in different rats of the same group and also, minor variations can be observed in different parts of the same liver. When these points are considered, among other things, the presented minor improvements in histopathological changes in the CCl_4 + herbal drug-treated groups as compared to CCl_4-control group may not represent good hepatoprotection.

Thus the reported data show, at best, a marginal hepatoprotective effect in *P. amarus*-treated rats. Considering all the parameters studied, the hepatoprotective effect of *P. debilis* is also below 50%. A reasonably good hepatoprotective agent should exhibit, at least, 60–80% hepatoprotection as seen in the case of normal recovery, 6 days after CCl_4-treatment (Table A). Drugs exhibiting at least 60–80% protective effect, preferably 80–100% protection, may be considered as hepatoprotective agents for treatment in crude forms after establishing their safety.

Although *P. debilis* showed moderate/slight hepatoprotection it should be noted that this effect of *P. debilis* was observed at a dose which gave maximum effect (0.66 g drug powder/kg body wt). The dose response effect is very important, and the data for the same are not given. The effect may not be seen or deleterious effect may be present at higher doses. Caution is required to use those drugs which do not give a normal dose response curve. Arbitrary dose fixation in herbal-drug treatment can result in the loss of moderate/small hepatoprotective effect of *P. debilis*.

Many common hepatoprotective medicinal plants are shown to have more than 60% hepatoprotection in most of the relevant biochemical parameters. However, comparison with published literature is sometimes difficult owing to the difference in the level of liver damage induced by various hepato-toxic agents (CCl_4, paracetamol, galactosamine, etc.) and in treatment protocol. To determine effectiveness as a hepatoprotective agent it is always better to compare with a hepatoprotective drug known for its efficacy and/or formulations such as Liv52.

We have studied both *P. debilis* and *P. amarus* and could not find substantive hepatoprotective effects in these herbs. We have observed relevant serum

Table A. Hepatoprotective effect of *P. amarus* and *P. debilis* in rats (% hepatoprotection)

Parameters	Groups			
	CCl_4-control	CCl_4 + *P. amarus*	CCl_4 + *P. debilis*	CCl_4 (Normal recovery in 6 days)
GPT	0	63	98	60
GOT	0	36	45	65
Alk. P	0	8	57	80
RNA (liver)	0	12	28	67

Percentage of protection was calculated as follows, assuming that there was no protection (100% damage) in CCl_4-control group

$$\text{Percentage of protection} = 100 - \left(\frac{100}{\text{Difference in the values between } CCl_4 \text{ control and normal control}} \times \text{Difference in the values between } CCl_4 \text{ control and } CCl_4 + \text{drug group} \right).$$

enzymes, bilirubin, choleretic activity and liver histology to assess liver damage and protection from damage. In our studies on *P. debilis* we have found only 30–40% protection from paracetamol-induced elevation of serum enzymes and bilirubin at a dose of 1 g dry powder/kg body wt and we consider it as a small effect. In our screening we could detect *Phyllanthus* species which give 80–100% hepatoprotection regarding most of the biochemical parameters and liver histology.

There are numerous medicinal plants which have marginal or insufficient curative potentiality. Reporting them as effective or potent herbal remedies is misleading and dangerous to those who want to use them as remedies. Such reports will increase the numbers in the long list of hepatoprotective herbal drugs but not provide hepatoprotection to the patients.

A. SUBRAMONIAM

Ethnopharmacology Division,
Tropical Botanic Garden and
Research Institute,
Palode, Trivandrum 695 562, India

R. T. Sane et al.'s reply

The publication presented the preliminary findings of our studies on the two *Phyllanthus* sps. We have not claimed *Phyllanthus debilis* to be the best hepatoprotective agent. The publication was initiated because our surveys indicated that all species of *Phyllanthus* are being used as hepatotonics with no species considerations. The study has brought out clearly the species-dependent variation in the hepatoprotective action and highlights the need to be very selective in their use.

Statistical comparison of treated groups with the normal control group is justified because the extent of recovery after treatment will be better evaluated with normal liver rather than a damaged one, as suggested by A. Subramoniam (AS). Even if such a comparison is made, no significant changes will occur in our evaluation. We have not claimed complete hepatoprotection in our findings.

We regret inadvertent error of marking the normal values also with asterisks. The SD of group II is 0.7284 and has been reported correctly. Several papers have been published, which clearly show that *P. amarus* is not a good hepatoprotective agent. The suggestion about adding plant control group is good. We appreciate the analysis of percentage hepatoprotection for each of the experimental groups. It is evident that *P. debilis* is a better hepatoprotective agent than *P. amarus*. The recovery seen in normal recovery group is after a period of six days, whereas the recovery in plant-treated groups is after three days. Average recovery seen for each group from AS's analysis is given below:

CCl_4 control	CCl_4 + *P. amarus*	CCl_4 + *P. debilis*	Normal recovery
00%	30.0% after 3 days	57.0% after 3 days	68% after 6 days

It is very clear that the rate of recovery by natural regeneration is slower than the *P. debilis*-treated group. Besides, published papers indicate that complete recovery after CCl_4-induced damage is achieved only after two weeks. We do agree that there is better recovery of RNA levels in natural recovery group.

The photograph of normal liver histology was not provided since the structural characteristics needed no special mention. After scanning the entire liver area, the most representative area was reproduced and we do not consider the improvement seen in them as minor but, quite significant.

The dose of the plant slurry was not fixed arbitrarily. We have carried out a dose–response study, after which the specific dose of *P. debilis* was fixed. The details of these findings could not form part of a short research communication. We agree that dose fixation is very important to avoid doses of deleterious effects or no effect. In fact, we have also carried out toxicity studies on these plant slurries. In the light of the findings from these studies we found the dose of 1 g/kg to be on the higher side and mildly toxic. This could be the reason why experiments with *P. debilis* could not provide satisfactory results.

It is also to be noted that various hepatotoxicants cause hepatic injury in different ways. Therefore, evaluation of hepatoprotective or hepatocurative actions need to be carried out with careful analysis to avoid over-interpretation. We are eagerly awaiting the publication on screening experiments by AS, where a *Phyllanthus* sp. is said to be identified, with better hepatoprotective action.

We have already initiated further studies on other *Phyllanthus* sps. and plan to use different hepatotoxicants. We have also carried out electron microscopic studies and have evaluated several other biochemical parameters. We are confident of publishing our findings soon. We still believe *P. debilis* to be a good hepatotonic.

Cryopreservation of epididymal spermatozoa

In 1949, Polge *et al.*[1] in England made a serendipitous discovery that glycerol protected fowl spermatozoa from the otherwise lethal effects of freezing. In 1953, Bunge and Sherman[2] demonstrated for the first time that frozen and thawed human spermatozoa could result in pregnancy and the birth of normal babies. All subsequent published reports have confirmed the cryopreservability of ejaculated seminal spermatozoa. The first semen bank in India was started at Apollo Hospital in January 1988.

Obstructive azoospermia is an important cause of male infertility. Surgical correction of obstruction yields poor results except when single tubular anastamosis is undertaken[3]. In some cases, surgical

correction is not possible (as in vasal-aplasia). However, in most of these men, a good number of spermatozoa with variable motility could be obtained by epididymal aspiration. It is not always possible to use the spermatozoa obtained by epididymal aspiration for Assisted Reproductive Technology as this requires an additional expense and simultaneous preparation of the wife. Therefore it was decided to try and cryopreserve epididymal spermatozoa obtained from caput epididymis (in men undergoing scrotal exploration) so that this could be used at a later date if necessary.

The subjects for the study were three men undergoing scrotal exploration for obstructive azoospermia in 1991. Informed consent was obtained from all these men. Epididymal spermatozoa were aspirated from caput epididymis into 1 ml of Earle's balanced salt solution. The prefreeze spermiogram was done. This was then mixed with an equal volume of Matheson Carlborg–Gemzell medium (cryoprotectant[4]) and cryopreserved in a biological freezer at $-70°C$.

Good motile spermatozoa were obtained from all the three men from caput epididymis. The sperm concentration prefreeze were twelve million, ten million and thirty-five million per ml with 30%, 40% and 60% progressively motile spermatozoa. Vaso epididymal anastomosis was done on two men. One man had vasal aplasia. One of these men, two months later, showed a sperm concentration of eighty million per ml with 30% motility and his wife was pregnant a month later. She has since delivered a baby. The other man had no spermatozoa at the first follow up, a month later, and has not reported back since then. As these three men were not keen on Intra Uterine Artificial Insemination Husband or ART for their wives, the spermatozoa so obtained from the caput were frozen with their consent. After one month the sample was taken out and thawed and it was found that the spermatozoa in all the three samples had still maintained 40–50% of their prefreeze motility.

Surgical correction of obstructive azoospermia generally yields poor results (20%). Unless and until experience is gained with single tubular anastomosis, the results of vaso epididymal anastomosis are not likely to improve. However, many centres have good experience with GIFT/IVF by conventional means or by Micro Insemination and Sperm Transfer (MIST), Sub-Zonal Insemination (SUZI) or Intra Cytoplasmic Sperm Injection (ICSI). For all these techniques, the number of spermatozoa required is far less than for *in vitro* fertilization. Therefore, while attempting vaso epididymal anastomosis for obstructive azoospermia, if the couple are prepared, one could also undertake IUAIH or ART. If, however, the couple are not prepared, one could attempt to cryopreserve the epididymal spermatozoa and use the cryopreserved spermatozoa for ART later if the surgical correction were to be unsuccessful.

All mammalian cells are not cryopreservable. It is not known what offers the spermatozoa the cryopreservable capacity. The fact that epididymal spermatozoa could be cryopreserved indicates that human spermatozoa do not require the presence of seminal constituents for being cryopreserved.

Epididymal spermatozoa which are mature, motile and capable of fertilization are also cryopreservable. It is suggested that all attempts at surgical correction of obstructive azoospermia should be accompanied by an attempt at IUAIH/ART or at least cryopreservation of epididymal spermatozoa so obtained.

Cytokine antagonism by active vaccination

The soluble mediators, known as cytokines, regulate immune response as well as effector phase of immune reactions. They are characterized by functional pleiotropy and redundancy and act as a 'network'. They are required for a number of normal reactions in the body but produce pathological changes when they are present at the wrong place and in wrong concentrations. Their role in a number of diseases has generated keen interest in the cytokine antagonists and their potential therapeutic use. The cytokine antagonists are nonpeptide molecules, soluble receptors, IL-1ra/ mutated cytokines and autoantibodies[1]. Besides these, the adverse effects of cytokines have been neutralized successfully by passive immunization of animals by anticytokine-antibodies[2–6]. On the other hand, the non-neutralizing type of antibodies contribute to a positive therapeutic response by better targeting of the cytokines to the appropriate cells[7,8]. We have successfully used a novel approach to actively immunize mice with a dengue virus-induced cytokine, the mouse Cytotoxic Factor (mCF), which acts as 'pathogenesis-related protein', to protect against the pathological effects[9]. We wish to draw attention to this potentially therapeutic approach of 'anti-disease vaccination'.

During dengue type 2 virus (DV) infection of mice, a unique cytokine mCF is produced by T lymphocytes. mCF is a 43 kD molecule on native PAGE and has an isoelectric point of pH 6.5. The sequence of 19 amino acids of the *N*-terminus of mCF (compared at Gen Data Base, Distributed Information Centre, Indian Institute of Science, Bangalore) differs from those of other cytokines and DV-specific proteins[10]. Northern blot tests done with the oligonucleotide probes derived from this sequence shows the presence of mRNA for mCF in the spleen cells of DV-infected mice. The cDNA library of mCF has been constructed in λgt 11 and expressed in *Escherichia coli*

(Chaturvedi *et al.*, unpublished data). mCF kills mainly H-2A negative macrophages and T helper cells etc. of a variety of animal species by inducing Ca^{2+} influx[11–14] and nitrite production (A. Misra, R. Mukerjee and U. C. Chaturvedi – communicated). mCF is capable of reproducing various pathological lesions that are seen in human cases of dengue haemorrhagic fever/shock syndrome (DHF/DSS) which include increased vascular permeability and damage to the blood–brain barrier[4,6] (Figure 1). Treatment of human blood leucocytes with mCF *in vitro* produces changes[15] that are described in cases of DHF[16].

Recently, presence of an mCF-like cytokine has been shown in the sera of the cases of DHF/DSS (ref. 17). This human CF (hCF) has been purified by chromatography and characterized (Chaturvedi *et al.* – unpublished data). Further, production of hCF by human peripheral blood CD4 positive T cells has been shown by *in vitro* stimulation by DV (ref. 18). T cell-enriched subpopulation could be stimulated directly to produce hCF but the yeild of hCF was enhanced in the presence of monocytes/macrophages (Mϕ). This shows that the effect of DV can be both direct or via monocytes. The Northern blot analysis using oligonucleotide probe prepared on the basis of amino-terminal sequence of mCF shows the presence of mRNA in T cells[18]. A number of characteristics of mCF are shared by hCF (Table 1), including molecular weight, reaction in Western blots and capacity to increase capillary permeability[19–22] (R. Mukerjee and U. C. Chaturvedi – communicated). This is an extremely important breakthrough in DHF research as mCF has been shown to be a 'pathogenesis-related protein' in mice.

Mice immunized with 5 μg of mCF mixed with Freund's incomplete adjuvant were challenged with 3 μg mCF at weekly intervals up to 48 weeks. Protection against the mCF-induced increase in capillary permeability and damage to the blood–brain barrier was studied in normal control and immunized mice. A complete protection is observed at the 4th week which persisted at higher levels up to the 16th week and then declined sharply. A breakthrough in the protection occurred with higher doses of mCF in a dose-dependent manner. mCF-specific antibodies are present in the sera obtained from the immunized mice as detected by ELISA and Western blot test and by neutralization of the cytotoxic activity of CF *in vitro*. The peak antibody titres correlated with peak protection. Intracerebral challenge with a lethal dose of DV prolongs mean survival time and delays onset of symptoms of sickness in immunized mice compared with normal mice, but the titre of the virus in the brain was similar[9]. Recently, the effect of various adjuvants, including Freund's incomplete adjuvant, alhydrogel, bacille Calmette-Guerin (BCG), normuramyl-L-*N*-methylalanyl-D-isoglutamine octalymide (compound No. 84/246, synthesized at the Central Drug Research Institute, Lucknow and kindly provided by K. B. Mathur) and tetanus toxoid (TT) on the immunogenicity of mCF and their optimum doses have been studied. The best effect is obtained with 84/246 followed by that with TT (ref. 20).

Paralysis and death of mice occur due to replication of DV in the neuron cells, while damage to the blood–brain barrier resulting in cerebral oedema and associated symptoms is caused by both virus and mCF. On the other hand, cerebral oedema is produced, but not the mortality, by mCF on intraperitoneal (i.p.) inoculation of mice with DV, as the virus does not enter the brain[6]. By mCF-immunization, neither the virus titre nor the DV-induced paralysis and death could be prevented, but the latter are significantly delayed by 3–9 days and the mCF-induced pathological lesions are prevented[9,20]. The immunization provides almost 90% protection against damage to the blood–brain barrier on challenging with DV i.p. Therefore, this approach may be very useful in cases where the virus does not enter the central nervous system (CNS). For example, in the cases of human dengue, signs and symptoms of cerebral oedema and rarely of encephalitis may be observed but the virus has never been detected in their CNS[6]. In spite of extensive work done to understand the pathophysiology and pathogenesis of DHF/DSS, the precise mechanism remains unclear[23], necessitating an indepth understanding of the pathophysiology of dengue syndromes to possibly open up new strategies to develop efficient vaccines.

Dengue illness is one of the most rapidly expanding diseases of the tropics, with over two billion people at risk of infection and millions of cases occurring every year[24]. The epidemics of dengue are widespread in this country and repeatedly occur year after year[25]. Dengue viruses are of four closely related types and yet each is sufficiently distinguishable from the others, such that sequential infection may lead to life-threatening haemorrhages and shock reactions. This has caused several problems in the development of a vaccine with the result that no vaccine against dengue is yet available for general use. The ultimate

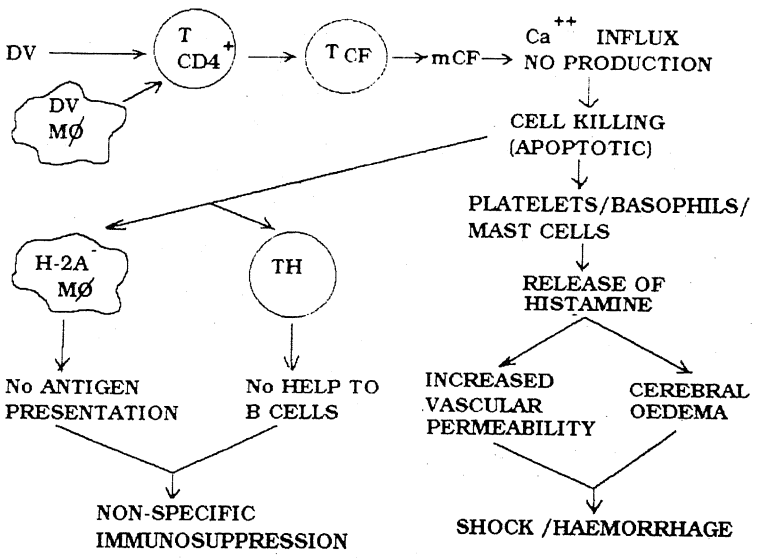

Figure 1. Production and mechanisms of action of mouse cytotoxic factor[19].

Table 1. Comparison of mouse (mCF) and human (hCF) cytotoxic factor[19]

Property	mCF	hCF
Inducer	DV[21]	DV[18]

aim for dengue vaccine development should be the prevention and control of haemorrhages and shock which are life-threatening rather than the milder form of benign dengue fever. The data obtained so far indicate feasibility of developing an 'anti-disease vaccine'[9,20] for prophylaxis against DHF/DSS. On analysis of amino-terminal sequence of mCF[10] (at Gen Data Base, Bangalore) a projection of three antigenic sites was obtained on the molecule. Recombinant CF (rCF) has been obtained by expression of λgt 11 packed with cDNA in *E. coli* and some of its properties have been compared which show similarity between the native mCF and rCF (U. C. Chaturvedi – unpublished data). A question that needs to be addressed is whether such a vaccine could ever find practical use because it is based on immunization against a self-protein. Presence of autoantibodies to a number of cytokines have been described and their role were discussed[1]. Anticytokine autoantibodies are known to block the activity of the cytokines and are found in the serum for interleukin-1a (IL-1a), IL-2, IL-4, IL-6, IL-8, IL-10, TNF-α and IFN-α. Small complexes between such antibodies and cytokines do not activate complement if IgG4 antibodies are involved, and do not precipitate *in vivo*, but are active as inflammatory complexes, therefore, their therapeutic use should be considered carefully[1]. Bendtzen *et al.*[7] have proposed that a major role of anticytokines autoantibodies is to facilitate, rather than neutralize, functions of cytokines in the body by acting as specific physiological carriers and regulators of cytokines. For effective immunization it is essential that such epitopes on cytokines are used which generate neutralizing antibody only. This approach has the advantages and disadvantages of an active vaccination, but vaccine strategies directed at the primary cause (the cytokine) rather than infective agents need serious consideration, more so when effective vaccines are not available for several agents.

Driven up the tree: Why do wild dogs harass leopards?

Anindya Sinha

A pack of Asiatic wild dogs or dholes suddenly appear on a grassy knoll in the darkening forests of the Mudumalai Sanctuary in southern India. They whine, sniff, rub against each other and then, as fleetingly, vanish into the dusk.

Why do carnivores like the dhole live out ardently social lives—hunting, feeding and resting together? Various selective advantages have been believed to accrue to communally living carnivores like wild dogs, lions and cheetahs. These include an increased likelihood of defending a territory with its associated resources of food and mates, greater success through cooperative hunting, and a better ability to protect kills from other predators. In an article in this issue, however, Arun Venkataraman provides tantalizing evidence for yet another kind of advantage that wild dogs, living in large cooperative groups, may enjoy[1]. He describes four instances where two of his study packs, which he has been studying continuously for five years now, actively mobbed leopards by grouping together and surrounding the trees in which the latter had taken refuge. In contrast, however, on a single observed occasion, the dogs bunched up and retreated from a tiger. This, together with the observation that leopard faeces contain more dhole hair than do those of tigers, leads Venkataraman to speculate that the wild dogs may be harassing leopards to deter them from preying on dogs isolated from the pack during hunting expeditions or on unprotected pups left behind in dens.

A competing hypothesis to explain the agonistic interactions of dholes preferentially towards leopards would suggest that the leopard's prey significantly overlaps with that of the dogs, while the prey of the tiger does not; competition for similar food may thus lead dholes to drive away leopards from their home range. In order to strengthen his own viewpoint, Venkataraman argues against this hypothesis rather convincingly. He shows that not only is there considerable overlap between the diets of the dhole–leopard, dhole–tiger and leopard–tiger pairs of carnivores, but the overlap is rather similar for the three pairs. Further support against the hypothesis comes from yet another interesting angle. Although leopards and dholes compete for similar-sized prey, there appears to be a niche-partitioning between the two predators based on the age- and sex-differences of the prey species. Thus, the dogs appeared to prey more on fawns or aged chital individuals; there was no such age-based selection by leopards. Moreover, dholes had a preference for male chital which the leopard did not. In conclusion, one important reason why dholes do live in large packs may therefore be to deter predation by leopards – surely a refreshing change from our familiar everyday dog-chase-cat situation!

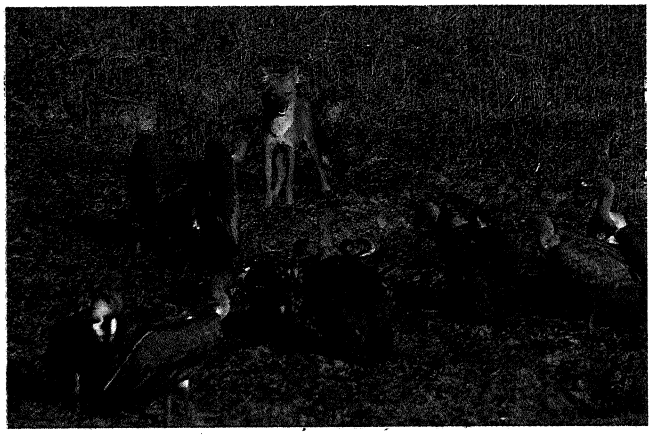

Figure 1. Dhole tensely approaching chital, killed by its pack earlier. Competition between vultures and the dholes is evident. (Photo: R. Sukumar).

The excitement of academic progress in any field of study can be easily judged from the gamut of refreshing ideas that challenge earlier theories and open up new avenues of research. Venkataraman's study is a valuable addition to studies on the behavioural ecology of social carnivores. Can other ideas be envisaged as one observes a pack of wild dogs mobbing a leopard that has been driven up a tree? Do all individuals participate in these attacks with equal enthusiasm? Are there dogs who cheat the rest of the pack by slinking away and leave the risky task of taking on the leopard's might to others? If indeed some individuals do so, are the other members of the group aware of them? Is there retribution for such cheating? Or do individuals move away boldly and are not punished since they serve the pack in other ways – by being good hunters or able defenders of the pups?

We now move away from a scenario where genetically related animals in a pack gain indirect fitness by helping one another. Is it possible that the dogs may potentially further their own individual fitness by displaying before each other their prowess in challenging a formidable adversary (V. Nanjundiah, pers. commun.)? Could this be a testing ground where individuals evaluate each other's strengths and capabilities as they plan future coalitions, challenges to the existing dominance hierarchy or even the choosing of mates? There is now increasing evidence that in many social systems such as those of carnivores and primates, individuals may be more aware of each other's strengths and weaknesses than was previously believed. In a recent study on African lions, for example, it has been shown that in coalitions of two individuals setting out to defend their territory from invading foreign animals, the more active individuals evaluate and appear to be aware of certain companions who persistently lag behind during such risky operations[2].

But given its scope and the fact that such detailed studies on the behavioural ecology of Indian wildlife are rare, there is no doubt that Venkataraman's study should provide a number of exciting answers in the years to come.

Some remarks on random numbers

K. R. Parthasarathy

It is shown that the number of k-peaks in a sequence of n random numbers and the time at which a k-peak occurs for the nth time in an infinite sequence of random numbers are asymptotically normally distributed. Exact expressions for their means and variances are evaluated.

IN his twenty-first convocation address 'Uncertainty, randomness and creativity' delivered at the Indian Statistical Institute, Calcutta on 5th March 1987, C. R. Rao[1] brings to our attention, in his characteristic style, an attractive feature of random numbers:

'It is an interesting property of random numbers that, like the Hindu concept of God, it is patternless and yet has all the patterns in it. That is, if we go on generating strictly random numbers we will encounter any given pattern sometime or other. Thus, if we go on tossing a coin, we should not be surprised if 1000 heads appear in successive tosses at some stage. So we have the proverbial monkey which, if allowed to type continuously, can produce the entire works of Shakespeare in a finite though a long period of time. . . .'

Continuing in this vein he deals with the following example:

'It is found that population sizes of a large variety of animals exhibit roughly a three-year cycle, i.e., the average time that elapses between two successive peak years of population size is about three years. (A peak year is defined as a year in which there are more animals than in the immediately preceding and immediately succeeding years.) The ubiquity of such a phenomenon led some to believe that perhaps a new law of nature has been uncovered. The belief was dealt a mortal blow when it was noted that if one plots random numbers at equidistant points, the average distance between peaks approaches 3 as the series of numbers gets large. In fact, such a property is easily demonstrable by using the fact that the probability of the middle number being larger than the others in a set of 3 random numbers is $\frac{1}{3}$. This gives an average distance of 3 years between the peaks.'

Here we elaborate on these comments by presenting a more detailed but elementary analysis of the frequency of occurrence of peaks (of arbitrary order) in a sequence $\{\xi_n\}$, $n = 1, 2, \ldots$ of independent and identically distributed random variables with a continuous distribution function $F(x)$. We may and do, without loss of generality, assume that ξ_n is uniformly distributed in the interval $[0, 1]$. This can always be achieved by considering the transformed sequence $\{F(\xi_n)\}$. We would consider this as a good pedagogical illustration of the individual ergodic theorem of Birkhoff and the central limit theorem for an m-dependent stationary sequence of random variables[2].

Say that a time point n is a k-peak for the sequence $\xi_1, \xi_2, \ldots$ if the event

$$E_n = \{\xi_n > \max(\xi_{n-k}, \xi_{n-k+1}, \ldots, \xi_{n-1}, \xi_{n+1}, \xi_{n+2}, \ldots, \xi_{n+k})\} \quad (1)$$

occurs. Clearly the probability of E_n is given by

$$P(E_n) = \int_0^1 x^{2k}\, dx = \frac{1}{2k+1}. \quad (2)$$

For $k = 1$, this is $\frac{1}{3}$ as mentioned earlier.

Denote by S the shift transformation defined by $S\xi_n = \xi_{n+1}$, $n = 1, 2, \ldots$. The distribution of the i.i.d sequence $\xi_1, \xi_2, \ldots$ is invariant and ergodic under S. For any event E denoted by 1_E its indicator which assumes the value 1 if E occurs and 0 otherwise. Then

$$\pi_{n,k} = 1_{E_{k+1}} + 1_{E_{k+2}} + \ldots + 1_{E_{n+k}} = 1_{E_{k+1}} + 1_{E_{k+1}} oS + 1_{E_{k+1}} oS^2 + \ldots + 1_{E_{k+1}} oS^{n-1} \quad (3)$$

is the number of k-peaks in the finite length sequence $\xi_1, \xi_2, \ldots, \xi_{n+2k}$. Note that the first likely k-peak in this sequence cannot be before the time $k+1$ and similarly the last likely k-peak cannot be after the time $n+k$. It now follows from the individual ergodic theorem of Birkhoff that

$$\lim_{n\to\infty} \frac{\pi_{n,k}}{n} = \frac{1}{2k+1} \text{ a.s.} \quad (4)$$

In other words the proportion of the number of k-peaks

K. R. Parthasarathy is at the Indian Statistical Institute, 7, S. J. S. Sansanwal Marg, New Delhi 110 016, India.

in a sequence of $n+2k$ random numbers converges almost surely to $1/(2k+1)$ as $n \to \infty$.

We shall now evaluate the variance of $\pi_{n,k}$. First observe that $1_{E_{k+r}}$ and $1_{E_{k+s}}$ are independent random variables whenever $|s-r| > 2k$. The covariance between $1_{E_{k+r}}$ and $1_{E_{k+s}}$ depends only on $s-r$ (and k which is fixed). The variance of $1_{E_{k+1}}$ is

$$\frac{1}{2k+1}\left(1-\frac{1}{2k+1}\right) = 2k(2k+1)^{-2}.$$

Thus

$$\operatorname{var}(\pi_{n,k}) = \frac{2nk}{(2k+1)^2} + 2\sum_{1 \le r \le 2k}(n-r)\operatorname{cov}(1_{E_{k+1}}, 1_{E_{k+r+1}}), \quad (5)$$

where 'var' denotes variance, and 'cov' the covariance. If $1 \le r \le k$ it is clear that $E_{k+1} \cap E_{k+r+1} = \phi$.

Thus

$$\operatorname{cov}(1_{E_{k+1}}, 1_{E_{k+r+1}}) = -\frac{1}{(2k+1)^2} \quad \text{if} \quad 1 \le r \le k. \quad (6)$$

For $k < r \le 2k$ we have

$$\begin{aligned}
&\mathbb{E}\, 1_{E_{k+1}} 1_{E_{k+r+1}} \\
&= P(\xi_{k+1} > \max(\xi_1, \xi_2, \ldots, \xi_k, \xi_{k+2}, \xi_{k+3}, \ldots, \xi_{2k+1}), \\
&\qquad \xi_{k+r+1} > \max(\xi_{r+1}, \xi_{r+2}, \ldots, \xi_{r+k}, \xi_{r+k+2}, \ldots, \xi_{r+2k+1})), \\
&= \mathbb{E}\,(\xi_{k+1}\xi_{r+k+1})^{r-1}\,(\xi_{k+1} \wedge \xi_{k+r+1})^{2k+1-r} \\
&= 2\int_{0<x<y<1} x^{2k} y^{r-1}\, dx\, dy \\
&= \frac{2}{(2k+1)(2r+1)}, \quad (7)
\end{aligned}$$

where $\wedge$ denotes minimum. Substituting (6) and (7) in (5) we conclude that

$$\operatorname{var}(\pi_{n,k}) = \frac{-2nk}{(2k+1)^2} + \frac{2k}{2k+1} + \frac{4}{2k+1}\sum_{r=k+1}^{2k}\frac{n-r}{2k+r+1}. \quad (8)$$

This implies

$$\lim_{n\to\infty}\frac{1}{n}\operatorname{var}(\pi_{n,k}) = \frac{2}{(2k+1)^2}\sum_{r=k+1}^{2k}\frac{2k+1-r}{2k+1+r} = \sigma_k^2, \text{ say.} \quad (9)$$

The following table gives the values of σ_k, $1 \le k \le 5$

k	1	2	3	4	5
σ_k	0.21082	0.16997	0.14517	0.12858	0.11655

By the central limit theorem for an m-dependent stationary sequence of random variables (see for example Theorem 19.2.1, ref. 2) we now conclude that

$$\left[\left(\pi_{n,k} - \frac{n}{2k+1}\right)\Big/(\sqrt{n}\,\sigma_k)\right] \overset{\text{in law}}{\Rightarrow} N(0, 1), \quad (10)$$

as $n \to \infty$, where $\Rightarrow$ denotes weak convergence and $N(0, 1)$ denotes the standard normal distribution with density function $(2\pi)^{-1/2}\exp -\frac{1}{2}x^2$. It may be noted that for large k, σ_k is approximately

$$\left\{\frac{2}{2k+1}\left(2\log\tfrac{4}{3} - \tfrac{1}{3}\right)\right\}^{1/2} = 0.38824(2k+1)^{-1/2}.$$

Denote by $\tau_{m,k}$ the time at which the mth k-peak occurs. Then

$$\begin{aligned}
P(\tau_{m,k} \ge n) &= P(1_{E_{k+1}} + 1_{E_{k+2}} + \ldots + 1_{E_{k+n}} \le m) \\
&= P(\pi_{n,k} \le m) \\
&= P\left[\left(\pi_{n,k} - \frac{n}{2k+1}\right)\Big/\sqrt{n}\,\sigma_k \right. \\
&\le \left.\left(m - \frac{n}{2k+1}\right)\Big/\sqrt{n}\,\sigma_k\right]. \quad (11)
\end{aligned}$$

Putting

$$\left(m - \frac{n}{2k+1}\right)\Big/\sqrt{n}\,\sigma_k = \alpha$$

and solving for n we get

$$n = (2k+1)^2/4\ \{2\alpha^2\sigma_k^2 + [4m/(2k+1)] - 2\alpha\sigma_k(\alpha^2\sigma_k^2 + [4m/(2k+1)])^{1/2}\}.$$

From (10) and (11) we now conclude that

$$\lim_{m\to\infty} P\left(\frac{\tau_{m,k} - m(2k+1)}{\sqrt{m}\,\sigma_k(2k+1)^{3/2}} > -\alpha\right) = \frac{1}{\sqrt{2\pi}}\int_{-\alpha}^{\infty} e^{-x^2/2}\, dx.$$

In other words

$$\sqrt{m}\,\frac{(\tau_{m,k}/m) - \overline{2k+1}}{\sigma_k(2k+1)^{3/2}} \overset{\text{in law}}{\Rightarrow} N(0, 1) \quad (12)$$

as $m \to \infty$. Roughly speaking the average length of the

time interval between the two successive k-peaks is $2k+1$. When $k=1$ this is 3 as pointed out in the beginning.

It is not difficult to see that the joint law of

$$\left[\sqrt{m} \left(\frac{\tau_{m,j}}{m} - \overline{2j+1} \right), \; j = 1, 2, \ldots, k \right]$$

converges to a k-dimensional normal distribution with a nondiagonal covariance matrix as $m \to \infty$. The asymptotic results (10) and (12) provide a series of large sample tests for testing the hypothesis that a sequence of numbers is random.

Biodiversity conservation information network: A concept plan

C. P. Geevan

A network that ensures the availability of reliable, up-to-date environmental information is necessary to realize the objectives set out in Convention on Biodiversity (now a treaty) that followed from the Earth Summit at Rio, June 1992. The task of building a nature conservation information network should, therefore, be considered an important part of the biodiversity conservation agenda. This paper presents an outline of an hypothetical information network, designated as Conservation Information Network (CiNet), to meet requirements of bioresources conservation, mapping, inventorying and monitoring on a large scale. The dataflow framework presented takes into account the existing data networks in India.

Background

The Convention on Biological Diversity (CBD) that emerged from the United Nations Conference on Environment and Development (UNCED) or the Earth Summit at Rio de Janeiro, in June 1992 is now a treaty. The CBD covers almost every aspect of biodiversity conservation. Article 17 of CBD concerns exchange of information. However, it does not lay down any operational framework for achieving information exchange. Nevertheless, an information network that ensures the availability of reliable, up-to-date environmental information is necessary to realize the objectives set out in CBD. The existing information systems are considered to be inadequate to meet these challenges[1].

The task of building a nature conservation information network should, therefore, be considered an important part of the conservation agenda. This paper presents an outline of an information network to meet requirements of bioresources mapping, inventorying and monitoring programme. The hypothetical network is designated as Conservation Information Network (CiNet). The dataflow framework is presented taking into account the ready availability of well-developed data networks in India and the CiNet is conceptualized as an overlay network riding over the existing networks.

C. P. Geevan is in the Salim Ali Centre for Ornithology and Natural History, Kalampalayam P.O., Coimbatore 641 010, India.

Special interest groups on global networks

Computer networking has gone beyond setting up data links to creating information highways over which organizations and individuals are connected across the globe. The nature conservation efforts need to take advantage of these developments in information technology and create a niche for itself in the cyberspace. There are several important initiatives in this direction such as the INFOTERRA of the United Nations Environment Programme (UNEP) consisting of 170 national nodal points coordinated from the UNEP headquarters at Nairobi, the Environmental Resources Information Network (ERIN) in Australia with a biodiversity information system designed to meet the changing user needs, the Bio-diversity Information Network (BIN21) dedicated to the CBD with its secretariat at the Tropical Database

in Brazil, the Long-term Ecological Research Network (LTER) based in the University of Washington and the projects in Capacity Building for Biodiversity Information Management begun by World Conservation Monitoring Centre (WCMC) based in the United Kingdom and the BioNET-International proposed by CAB International to pool the global resources in biosystematics. With the assistance from the United Nations Development Programme (UNDP) under CAPACITY 21, a large number of Sustainable Development Networks are also expected to be set up.

The capacity building project of WCMC is supported by the European Union and allows it to carry out the strategic development work as well as testing of networking and other cooperative approaches for biodiversity information management. BioNET-International is a Global Technical Cooperation Network of institutions and people concerned with biosystematics of invertebrates and microorganisms. The goal of this network, as stated, is the mobilization and enhancement of the world's biosystematic resources for the benefit of developing countries. BioNET will build and sustain biosystematic self-reliance in developing sub-regions and provide the biosystematic backup to biodiversity.

Several special interest groups and networks (SIGN) dedicated to biodiversity conservation have sprouted up all over the global computer network. These SIGNs provide various facilities to users. Some of these are available to the email subscribers to the list. Subscribers usually join a list by sending an email with requisite information to the listserver or the master of the list. The user's name, email address and other information are then added to the email database maintained by the SIGN.

Biodiversity information networks in India: current status

There are a large number of Non-Government Organizations (NGO) and research organizations involved in conservation-related activities and research. India is not only rich in biodiversity, but can also boast of a large baseline information on this wealth. The repositories of this information are numerous and diverse, with some of the agencies being more than a century old. Invaluable information exists in a variety of forms: as specimens, field notes, reports and various kinds of computerized data.

Despite dramatic developments in information technology and quantum leaps in telecom facilities, the conservation efforts in India are yet to make the best use of the options available for information exchange, barring a few exceptions. The recent discussions on the mechanisms and scope of the information base for biodiversity conservation in India[1], is an indication of this realization. The information networks for biological conservation are at a formative stage, the front runner being the network initiative of the Foundation for Revitalization of Local Health Traditions (FRLHT).

The well-established and nationwide biological information network is the Bio-Technology Information System (BTIS) consisting of the Distributed Information Centres of the Department of Biotechnology supported by NICNET—the computer network of the National Informatics Centre (NIC). Another biological information service available is the access to the Medical Literature Analysis and Retrieval System (MEDLARS) over NICNET, provided to select institutions by NIC. The different institutions with access to MEDLARS do not, however, exist as inter-connected nodes.

Although FRLHT has taken an initiative in creating the Indian Medicinal Plants National Network of Distributed Databases (INMEDPLAN), it falls short of the larger needs of networking the conservation activity and bioresources mapping. This can only be met by the 'inter-networking' of several networks such as INMEDPLAN, BTIS and those in the offing like the Biodiversity Information System (BIS) of the Indira Gandhi Conservation Monitoring Centre (IGCMC) established by the World Wide Fund for Nature (WWF) and the Environmental Resources Information System (ERIS) being devised at Wildlife Institute of India (WII). The IGCMC proposals, unlike that of FRLHT, appear to favour an over-centralized system, rather than a true network of several fully autonomous, distributed information systems.

The INMEDPLAN is a network of organizations involved in identifying, documenting and reviving folk and traditional health systems and in the inventorying of medicinal plants. FRLHT has also attempted to bring about some sort of standardization in data compilation formats. A large number of organizations are also involved in the consultative process of standardization.

Although, the BTIS does not have conservation priorities, it provides rapid access to a wide variety of biological databases, besides those related to biotechnology. Moreover, considering the role that molecular biology and DNA fingerprinting are destined to play in biodiversity inventorying and monitoring, it is important to bring BTIS within the ambit of conservation network.

A recent study of biological databases available in India indicates that the majority of these are developed under BTIS[2]. Although the study does not appear to have examined the information resources available at reputed ecological research institutions, its overall conclusion that the contribution from sources other than BTIS is marginal, may have some validity. The same study also notes that the use of the available databases is restricted due to lack of electronic data transfer facility and networking. The BTIS users make use of NIC's

satellite-based network for data communication. However, BTIS does not function as a true on-line computer network due to certain limitations imposed by NICNET.

Both ERIS/WII and BIS/IGCMC/WWF are at an early developmental stage. It is important that the originators of these information systems lay down some long term networking and standardization goals as part of the design and development activity. What needs to be clearly recognized is that the highly centralized information systems relying on high performance computers are a thing of the past and the future belongs to inter-networking of special interest groups. With a highly decentralized and participatory approach to conservation, it becomes all the more important to anticipate the need for a truly extensive data network and take into account the multiplicity of end-user needs.

As important as access to information or even more, is the access to people and person-to-person communication on the network. It is such communication that makes the network come alive. The conservation effort in India, has an overwhelming need to create such a 'live' network, particularly because, informal networks of people and organizations exist and have been able to open up large areas of co-operative endeavour.

Information sharing: some contentious issues

The CBD introduces new elements into the ticklish question of information sharing across political boundaries. Even where national boundaries are not involved, there are many important matters of protocol and copyrights as well as the rights of local communities that need to be addressed for the network to be operational. However, it is better to take on the bull by its horns.

It has been argued, albeit with good intentions, that electronic exchange of biodiversity information will open a Pandora's box of possible infringements of national rights over genetic resources caused by information flow over global networks. Other contentious issues relate to intellectual property rights (IPRs) and cultural heritage rights in the context of CBD.

There is a view that until and unless these issues are fully resolved, it will be rather premature to think of electronic networks. However, what needs to be taken note of is that most of the information that may be available on these networks will in case be published sooner or later in journals. Publication of findings *per se* cannot be and should not be stopped, irrespective of the media used. Once published in journals, anyone around the globe can put that information out on a network. Thus, any blanket ban on information transfers on network cannot make sense today, when scientific journals are being available on CD-ROMs and almost every important journal is providing back issues as CD-ROM volumes.

It needs to be noted that in countries where the IPRs are enforced, rather stridently, that has not become a damper to information flow on networks. These services are being made use of in India, too, by scientists at research institutes in physical sciences and molecular biology as well as by the software developers. The IPR issues need not be a detriment to the emergence of CiNet. Besides, the network will only allow access to information that is open to public. It does not permit anyone to access any kind of information; all access being subject to the restrictions imposed by the network administrators.

The CiNet

The goal of CiNet is to create a voluntary, on-line 'live wire' network of researchers, government officials, ecosystem managers, executive decision makers, NGOs and local communities for biological conservation and sustainable development in India. It must be based on best available, cost-effective technologies and workable administrative arrangements. Instead of setting out to make large investments in infrastructure building, the network must make the best use of available facilities and function on a cost-sharing, no-profit-no-loss basis. To cut costs, the existing networks and access providers can be made active participants in this process.

The CiNet must play the following two roles: a) organize a loose network of organizations interested in conservation and b) establish a well-coordinated data network with features and functions similar to the special interest computer networks that exist elsewhere in the world.

The CiNet can succeed only by cooperating with other initiatives and by assuming an inter-networking role. The necessary administrative and technical protocols can be worked out to ensure meaningful cooperation and active collaboration among such organizations. The network must provide mechanisms at different levels for free information flow between these numerous organizations and between networks. The conceptual framework articulated here attempts to address the data flow challenges of the 'massive, decentralized' bioresources mapping exercise with the active participation of people, suggested by Madhav Gadgil[3]. He contemplates a 'nation-wide village level programme of mapping of natural and man-made habitats on the scale of a hectare or so'. The Panchayat Level Bio-Resources Mapping Programme, that he advances, involves teams of 'barefoot ecologists' under the guidance of taxonomic experts and are referred to here as Bio-Resources Mapping Teams (BMT).

The proposed CiNet consists of a network of Distributed Biodiversity Information Centres (DBIC) for data compilation, information processing and dissemi-

nation services assisted by several Field Studies Units (FSU) and BMTs. Selected institutions active in ecological research and willing to assist the CiNet activities could act as Associate Resource Centre (ARC) for the DBIC. These ARCs will also function as value adding nodes on the CiNet. The ARCs are expected to 'add value' by way of analysis and critical evaluation of the data as well as assist the BMTs. The data flow framework of the network is given in Figures 1 and 2.

The distributed information systems can be networked via land and satellite links making use of the telecommunication facilities and datalinks already available in India. The CiNet National Centre (CNC) can also provide decision support services to the Ministry of Environment & Forests, Government of India (MoEF) and other governmental agencies. The CNC will also be responsible for the overall co-ordination and technical support for the CiNet. In addition, the CNC will also carry out appropriate clearing house functions as the information travels across the network. The clearing house mechanisms will ensure reliability of the network and enforce quality control and validation checks on the data that is added to the central databases. The CNC must, therefore, have a technical secretariat for its clearing house functions. Ideally, the CNC could be located at a site where the best facilities and expertise in information technology as well as bioresources mapping, inventorying and monitoring are available.

The user community

The end users of the network are envisaged at different levels of decision making and management:

a) Macrolevel executive decision makers, national policy makers, planners, national institutions, national level NGOs such as WWF (India), inter-governmental organizations under United Nations, international development agencies and international institutions for the implementation of the CBD.

b) Decision makers, policy makers, managers, scientists, NGOs and individuals at the state, district and community levels.

c) Microlevel planners, community organizations and grass root level NGOs.

ARI, Agricultural Research Institutions; CNC, CiNet National Centre; CSGA, Central and State Government Agencies; DBIC, Distributed Bioresources Information Centre of CiNet; DBT, Department of Biotechnology, Government of India; DST, Department of Science and Technology, Government of India; ERI, Educational and Research Institutions; MOEF, Ministry of Environment and Forests, Government of India; User Nodes, See Figure 2.

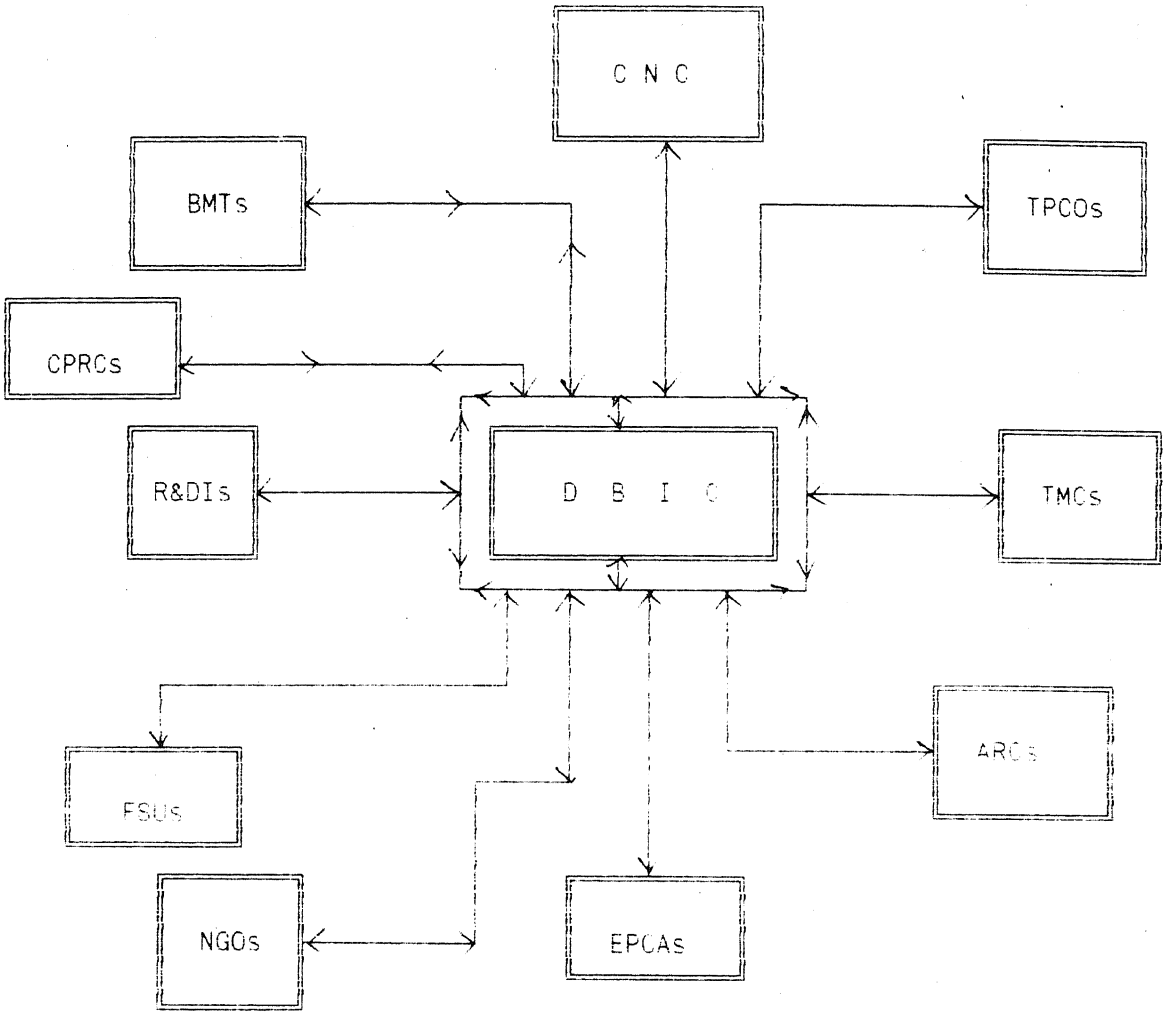

Figure 2. The logical network at a Distributed Bioresources Information Centre (DBIC). ARC, Associated Resource Centre; BMT, Bioresources Mapping Team; CNC, CiNet National Centre; CPRC, Common Property Resources Centre; DBIC, Distributed Information Centres of CiNet; EPCA, Environmental Protection/Conservation Authorities; FSU, Field Studies Unit; NGO, Non-Governmental (non-profit) Organizations; R&DI, R&D Institution; TPCO, Traditional People's Community Organization; TMC, Traditional Medicine Centre.

The CiNet can help the larger goals of biodiversity conservation by addressing the information needs of:

- protected area management
- short and long term ecological studies
- socio-economic studies and development programmes
- community-based development programmes
- adapting and improving the traditional methods of resource use
- local communities and bioresources mapping programmes.

The CiNet databases

Some of the major databases that must be organized under the CiNet are:

a) Data on the flora and fauna of India, with taxonomic details and information relevant for conservation of biodiversity.
b) Environmental impact and status data.
c) Sustainable resource use potential and practices; sustainable technological options; socio-economic profiles of sustainable resource use.
d) Hydrologic and agro-climatic and meteorological data.
e) Institutions, experts, resource persons and NGOs with information on area of specialization, infrastructure facilities, experience and catalogue information on educational software (printed materials and audio-visuals).
f) Bibliographic data extracted from on-line databases and those compiled from Indian publications not covered by international bibliographic services.
g) Metadatabases on information sources, specimen and

herbarium collections, map archives and photo/audio-visual libraries.

h) Socio-economic and demographic data relevant to ecosystem management and conservation.

Standards

The most important question that the network builders need to recognize and deal with is that of data standards. Certain standardization process is already on. However, a lot more remains to be done. Considering the large amount of information available in different forms, drawing up standards is an urgent need.

Some of the entities that must be accorded high priority for standardization (in alphabetical order) are:

- Abundance codes for trends and status.
- Bibliographic formats.
- Biodiversity mapping grid identification codes relating it to survey of India toposheets.
- Biogeographic site descriptors.
- Biosystematics.
- Conservation status descriptors for different levels of taxa.
- Degradation/disturbed area classification.
- Descriptors of anthropogenic pressures on ecosystems.
- Directory of castes and tribes based on the data from Anthropological Survey of India's Peoples of India Project.
- Distribution classes associated with different taxonomic levels.
- Ecological classification/habitat types and classes.
- Faunal and floral attributes or a simplified taxa identification key system.
- Landuse-related descriptors.
- Location identity/site codes.
- Macro- and micro-climate types.
- Resource use-related descriptors.
- Soil-related descriptors.
- Species–species relationships/associations.
- Water: Nutrient and water quality-related indices.

Geographical information system (GIS) and biodiversity maps

The CNC must be equipped with state-of-the-art work-station-based GIS facilities while at each DBIC, either a middle or entry level based GIS facility that can be run on a personal computer must be established or arrangements must be made for sharing GIS resources with a well-equipped ARC. The GIS makes it possible to make use of computers for the analysis of spatial data. The spatial data such as maps are first converted into computer readable form. This is achieved using hardware such as scanner or digitizer. GIS can also make use of satellite imageries and compare such images taken at different times. It is also possible to overlay these computerized maps with information collected from ecological surveys by the FSUs. The data residing on well-structured databases can also be incorporated into the GIS to produce spatial representation and visualization of such data. It is also possible to undertake substantive statistical analysis of the spatially aggregated data.

The GIS facilities at the DBIC must provide facilities for updates and retrievals of spatial data for use by the FSUs. Therefore, besides computer systems, requisite input/output and display devices like large high resolution colour video display units, digitizers, scanners and colour printers need to be installed at the DBICs. These facilities only need to be added to the DBICs in a phased manner keeping in step with the growth of the bioresources mapping programme.

CiNet needs to work towards developing a comprehensive GIS-based bioresources map library and make it available on-line to the CiNet users. Since the spatial scales envisaged for the biodiversity map grids under the bioresources mapping programme is of the order of 1 to 10 hectare grids, the map libraries must organize spatial data on maps of very large scale. In practice, it will be difficult to organize map libraries for 1 hectare grids and it may be necessary to opt for larger biodiversity mapping grids of nearly 1000 hectares.

Information-sharing mechanisms

The major databases of CiNet must be organized using database management system technologies that conform to industry standards. It is desirable that the large central databases of CiNet are well-structured based on relational database management concepts. Such well-structured databases can be used to hold the authenticated baseline data, with a bare minimum of essential details. It is also necessary to develop multimedia databases that can include text, pictures and sound. These databases will reside on servers providing access to data in several ways. However, as pointed out earlier, information on computers is not organized merely as well-structured databases; there is certainly a lot more to information sharing via networks, than databases. Besides well-structured databases, information needs of the network users have to be met in several other ways as well. A recent workshop that examined the linking mechanisms for BIN21 concluded that the best approach was for it to function as a SIGN having several participating nodes with web servers[4].

Typically, the information on a network will consist of non-database entities such as documents, graphic objects, messages, news bulletins, reports on new findings, electronic journals, file archives, and large amounts

of information organized in a hypertext format. The network has to provide nodes with servers that can provide a host of services available on the Internet, which is a 'network of networks' linking computers all over the globe. The CiNet can be built by creating an exclusive network of members or by becoming a part of the global Internet community. The later option is cost effective and it is possible to make use of the Internet connectivity in collaboration with the Education and Research Network (ERNET) project. The ERNET infrastructure can be augmented to meet the needs of CiNet. It must be noted that the users will have varying degrees of difficulty in network access. Therefore, a host of linking mechanisms, that allow connectivity by means of low speed dialup telephone lines as well as high speed links over leased telephone lines, satellite links and public data networks, must be made available to the CiNet users.

The networks on Internet maintain mail lists, news bulletin boards, special interest groups, file archives and help individuals find the right information or the right contact. The main Internet tools are Gopher, World Wide Web (WWW) and the Wide Area Information Server (WAIS). The information available on Gopher servers are limited to text. Gopher organizes information in a hierarchical menu-based system, analogous to the table of contents of a book. The WWW uses hypertext links to connect together pieces of information contained in documents located at different nodes. The information in the documents is organized using the HyperText Markup Language (html). Files are transferred using the HyperText Transfer Protocol (http) and the File Transfer Protocol (ftp). The WAIS is a client-server tool that can be used to search and retrieve files, based on full test indexing of the contents or titles.

These Internet services can be organized on a cost-sharing basis with the major initiative coming from a large organization or university. The network must provide all or some of these facilities, besides off-line email. The CNC and each DBIC must set up a WWW or Gopher. The CNC need to operate listservers and bulletin boards. The CNC also need to provide access to major databases. The DBIC must provide user access to on-line searches on the databases located at any of the DBIC or CNC.

It is important that besides email, CiNet users have access to Internet services such as ftpmail and mail-gopher. The DOS or Windows-based PCs connected to the DBICs using modems can be provided shell accounts on the servers at the DBIC. Those nodes which can be connected to the DBIC servers using high speed links or leased telephone lines can make use of the services such as Gopher, WWW or WAIS. Each of the BMT, FSU or ARC must have *at least* email access, and if possible other facilities based on TCP/IP. The TCP/IP (Transmission Control Protocol/Internet Protocol) is a way of packaging data for easy movement between many different computer systems. It consists of a collection of search, retrieval and communications utilities. Personal computers running DOS/Windows can make use of the network services by means of either the Serial Line Internet Protocol (SLIP) or the Point-to-Point Protocol (PPP) with the TCP/IP stack up and running on the PC, provided the DBICs offer SLIP or PPP accounts on the servers.

To facilitate network connectivity there are certain software and hardware needs. To enable simple email facility for a CiNet user equipped with a PC, all that is needed is a mail service account on the DBIC server, a telephone, a modem and a communication software loaded on the PC to enable terminal emulation after getting connected to the DBIC server. The DBICs, also need to have facilities for remote users to login via telephone lines and must therefore have the DBIC server also connected to the telephone lines through modem. The modem speeds in this can be even as low as 300 bits per second (bps) and faster modems can be used where higher speeds can be attained. The computer at the user end can also be a multi-user system running UNIX. If only a dialup link with the DBIC is possible, then an UUCP (Unix-to-Unix Copy) account can be created on the DBIC server to transfer email as a fully automated service.

If the user has access to better communication facilities such as the X.25 based connection or a leased high speed telephone line to a DBIC server, and the computer system at the user end is multiuser running any port of System V Release 4 UNIX complete with X/Windows Graphical User Interface and TCP/IP, then all the network services can be made use of. Email can be transferred using the Simple Mail Transfer Protocol (SMTP) rather than UUCP. Several other facilities such as FTP and TELNET for remote login to the CiNet servers will also become possible. A high speed modem is needed because if the user is to make the best use of network services, connectivity must be achieved at speeds of 14.4 kbps or above. Otherwise the network access can become very tiresome. High speed modems and interface cards are required at both ends.

Software support is needed by way of the communication protocols (TCP/IP and SLIP or PPP). Both the PC at the user's end of the CiNet and the DBIC server of the CiNet must be running either SLIP or PPP as well as the versatile TCP/IP. With the software and hardware (interface cards on the computers and the modems) in place, the user will have full access to all the public information resources on the CiNet as well as Internet, assuming that CiNet has full Internet connectivity.

The field units which are the key to the biodiversity mapping programmes also need to remain 'online' with

the DBICs. Very often the FSUs may be conducting surveys in remote locations with no possibility of access to telephone links. It is, indeed, possible to resort to wireless data transmission to access the nearest DBIC when such a need arise. There are, of course, certain legalities to be sorted out in order to realize this technical possibility because of the restrictions imposed by the laws governing wireless communication. Sometime in the near future, mobile telephones that can be used from any geographical location will be available. The costs of such systems may, indeed, be rather high at the introductory stage. When the use of such devices becomes more widespread and cheap, the FSUs can use it for establishing dialup links with the DBICs.

Communication options

The CiNet is conceived as a loose network of organizations that can share information on a cost-sharing basis. It can make use of the different computer networks available such as the satellite-based NICNET services using Very Small Aperture Terminals (VSAT) and the ERNET services based primarily on terrestrial dial up links. ERNET, too, is expected to provide access via VSAT soon.

There is no need to go through the whole cycle of developing networks and physical links, since the network can be developed using the data communication facilities available in the public and private sectors. In a national context where many data networks already exist, the feasible low investment proposition is to make the best use of existing network infrastructures on a cost-sharing basis and let the CiNet 'evolve' on its own as the activity increases. ERNET with its vast experience in networking, can possibly play a pivotal role in establishing the required network facilities and CiNet can ride over the ERNET.

There are, indeed, several communication options available. Depending on what is appropriate at each level of the data flow, the best option has to be exercised. The national network of DBICs and the CNC that make up the CiNet need to be linked by high speed links. The VSAT based links is a reliable option. Another possible option is to go in for the INET facilities offered by the Department of Telecommunications (DOT) which allows X.25 based communications. The X.25 is the name for a widely used network layer protocol described by the International Standards Organization (ISO) and the International Telegraph and Telephone Consultative Committee (CCITT).

The wide area network (WAN) services can be implemented by establishing permanent physical connections using dedicated lines or private lines, by circuit-switched physical connections based on dialup links and by demand digital service based on packet switching. A network of networks, typically, uses packet-switching methods. Rather than trying to establish a dedicated communication line between two computers located in the same or different network, which is rather clumsy when several computers are competing for connections, the inter-networking typically uses packet switching techniques. This is because packet-switching allows several computers to share communication links, by transmitting packets of information with an addressing system through the packet switching circuit.

Packet-switching has in-built error detection and correction mechanisms and provides dynamic re-routing of calls as well as interconnection of computers/terminals at different speeds. It will be far too expensive to build a private data network dedicated only to CiNet activity. The facilities provided by DOT on INET—a X.25 based Packet Switched Public Data Network—include permanent point-to-point connection between two end users of the circuit or multipoint connections between more than two end users.

Given the communication options available, the pros and cons need to be weighed carefully. While making the choice the following aspects are to be considered:

a) The communication option must ensure high speed connectivity to major national and international networks, particularly the NICNET, ERNET and INTERNET.
b) The communication link should not be prone to frequent breakdowns.
c) The recurring costs must be kept low.
d) The communication facility must support multiple protocols.

As network service providers, particularly in the private sector, make their bid for a slice of the Indian cyberspace, more options will be available for networking and CiNet itself can possibly become a value-adding, financially self-sustaining service provider with its specialized information resources.

Conclusion

The conservation of biodiversity is an enormously complicated and difficult task requiring information flow on an unprecedented scale. The conservation efforts need networking of individuals, organizations and information systems. Co-operation and collaboration on such a wide scale will be possible only with the support of an appropriate information network, such as the one presented here. The user demand, technical expertise and communication infrastructure for the creation of such a network exist in India and the network proposed here is envisaged as a self-sustaining one that is well

integrated into the existing data networks, particularly the rapidly expanding Internet community.

ACKNOWLEDGEMENTS. This work draws inspiration from the large scale bioresources mapping programme articulated by Prof. Madhav Gadgil. I thank the referee K. Gopinath, Indian Institute of Science, Bangalore, for the critical comments and Gopi K. Garge, Network Coordinator, ERNET, Indian Institute of Science, Bangalore who contributed valuable suggestions and ideas. This paper is dedicated to my late colleague Dr D. F. Singh, who was heading the Wetland Ecology Division and was working towards creating a database on fish diversity of the Western Ghats on CD-ROM.

Earth's core

S. K. Saxena

The new techniques of heating solids with a laser at ultra high pressure in a diamond-anvil cell are providing us with new data on equation of state properties of solid and molten iron. The new data on iron melting, which extends to a pressure of nearly 2 megabar (200 GPa), permits the thermodynamic extrapolation of the melting data to pressures corresponding to the centre of the earth. The new studies on iron have also prompted a search for new phases of iron possible at high pressure and temperature. The currently available data point to a rather simple compositional model of the core which is identical to the meteorite irons or stony-irons. The adiabatic temperature of the earth's centre may lie between 5980 and 6680 K.

SEISMIC data show that the earth's core consists of an outer part which has all the properties of a liquid and an inner core which is solid (Figure 1). The core, reaching to a depth of nearly 2900 km from its centre stores a substantial part of the planet's energy and, therefore, exercises significant influence on the dynamic processes in the mantle. From cosmochemical, geophysical and geochemical considerations, the dominant species in the core has to be iron. Iron occurs in four solid structural states, namely, δ (bcc), α (bcc), γ (fcc) and ε (hcp). The ε (hcp) is considered to constitute the bulk of the solid inner core. Although not experimentally shown but based on the available data on the compressibility of iron (ε), it appears that iron by itself has a density higher than the density of the core[1]. Therefore, it has been suggested by many geochemists that some additional light elements (e.g. sulphur, oxygen, Si) are mixed with iron to form a lower density inner core and a lower melting liquid outer core[2].

To understand the state of the core, it is important that the thermodynamic properties of liquid and solid iron are determined. Recent developments in generating ultra-high pressures in diamond-anvil cells with laser heating have made it possible to study properties of material at the core pressures and temperatures. The purpose of this article is to report these technical developments, the recent findings on iron and the status of our understanding of the earth's core.

Figure 2 shows a summary of the currently available experimental data, until the year 1993, on phase equilibrium relations obtained from static devices, i.e. techniques with *in-situ* heating of a sample under pressure

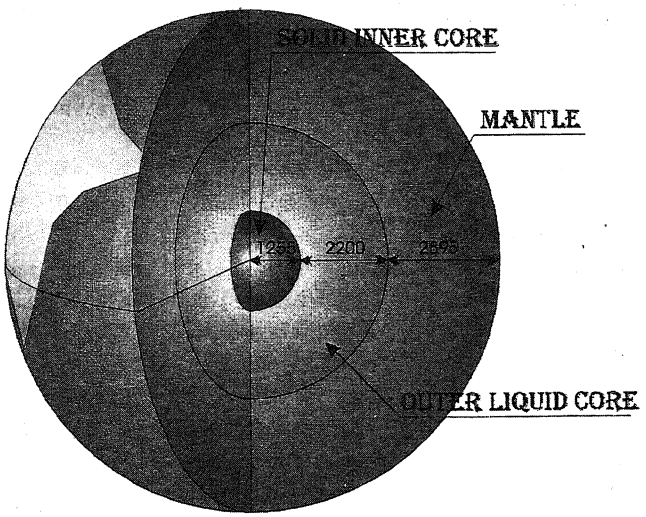

Figure 1. Earth's interior as determined by seismological data. The solid inner core with a radius of 1255 km is surrounded by a layer of molten iron with a shell thickness of ~ 2200 km reaching a depth of nearly 2900 km from the crust. The inner core density is close to 13 g cm^{-3} and its temperature is variously estimated as between 4000 and 8000 K.

S. K. Saxena is in the Institute of Earth Sciences, Uppsala University, S-75236, Uppsala, Sweden.

sustained over a period of time. The phase transition boundaries α–γ, γ–ε and α–ε meet at one point, the so-called triple point; at such pressure and temperature all the three forms of iron coexist in equilibrium. Recent theoretical study on iron properties at high pressure and high temperature by Anderson[3] has shown that an experimental determination of the data on ε–γ phase transformation and the ε–γ-melt triple point are particularly crucial in extending our currently available results to understand the state of the earth's core. The argument is that the pressure-temperature of the triple point determines the behaviour of the melting curve at high pressures. Thermodynamically, the pressure-temperature slope of the ε–γ phase equilibrium curve constrains the estimated enthalpy, entropy and other physical properties of the ε phase which are largely unknown. With the availability of the equilibrium data on the ε–γ phase transformation, one may assess the thermodynamic properties of the ε phase which in turn can be used in the estimation of the properties of the iron melt.

A triple point, similar to the one shown in Figure 2, should exist for the coexisting γ, ε and melt. All the available experimental data on the ε–γ transition (see Figure 2), appear to indicate that such a triple point would lie around 2700 K between 60 and 70 GPa. The problem is that Brown and McQueen[4] had located a solid–solid transition some years ago at 4400 ± 300 K at a pressure of 200 ± 2 GPa. As shown in Figure 2, this phase transition could not be the ε–γ transition. The triple point is located at too low a pressure for this to be possible. This apparent inconsistency between the sets of data led Boehler[5] to conclude that there should exist a fifth iron phase. The existence of this phase is supposed to solve two problems; first it would explain the phase transformation recorded by Brown and McQueen in their shock-wave studies and second, by creating a third triple point, it would let the melting curve slope appropriately to fit the existing geophysical data. This led to the start of a search for a new phase of iron and the determination of the iron melting at pressures higher than that at the core/mantle boundary (130 GPa). Achieving such extreme pressures in the laboratory requires special techniques, for example, the laser heated diamond-anvil cell.

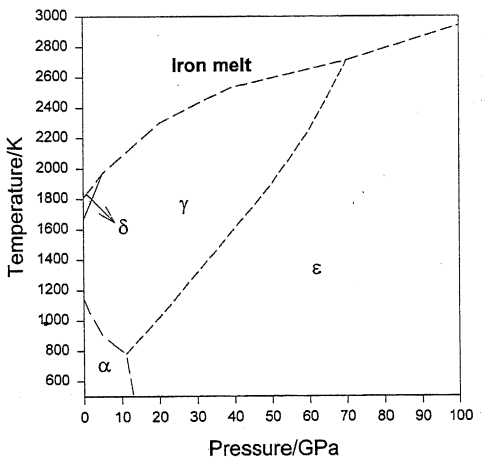

Figure 2. Phase diagram of iron from the available data up to 1993. The various curves drawn do not include the new experimental data. The stability regions are shown for the four iron polymorphs: δ (bcc), α (bcc), γ (fcc) and ε (hcp).

The diamond-anvil cell experimental set up for generating high pressure is discussed in several recent articles[6]. Here a brief description specific to Uppsala Laboratory is given (Figure 3). The laser heating system most useful for such studies is the one developed by Boehler *et al.*[7]. The use of a high power Nd : YAG laser (e.g. the one by Coherent) operating in CW TEMoo mode at a wavelength of 1064 nm is required. The laser provides maximally 35 W of vertically polarized light with a feedback controlled stability better than 0.5% peak-to-peak. The high pressure requires the megabar diamond anvil cell developed by Jephcoat *et al.*[8] for such experiments. To achieve real high pressures beyond 100 GPa, one needs to use the standard Drukker type IA beveled diamond anvils with 0.30 mm diameter flat culet faces (Figure 4). For the pressure determination the calibrated pressure shift of ruby R1 fluorescent line is used[8]. A phase transformation is determined by visual observation of melting when possible and by plotting the laser power against the temperature. At the temperature of phase transformation there is a distinct change in slope. The temperature is determined by spectroradiometry. The 50 μm in diameter slit of the

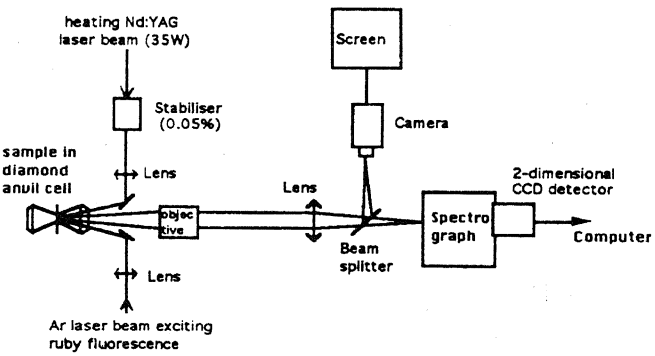

Figure 3. Experimental set up for the study of iron in a laser-heated diamond-anvil cell.

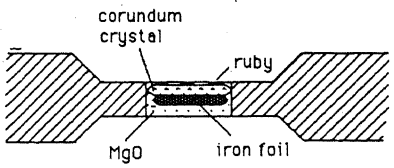

Figure 4. The sample environment in the experiment on melting. The iron foil is cushioned with MgO powder with a corundum plate on the top. Ruby chips are used for pressure calibration.

spectrograph collects the radiation from an area of 3 μm in width of the sample. A two-dimensional CCD detector is used to obtain temperatures measured over the entire length (30 μm) of the slit area. The temperature gradient over the central area (3 μm) is only a few degrees. The laser power fluctuations are minimized to a root mean square value < 0.5% by using a laser power stabilizer. In the method suggested by Boehler *et al.*[7] a ruby crystal is used on the top of the sample as an isolator and MgO powder at the bottom. The use of crystals eliminates the possibility of any significant reaction between the sample. In particular, at the sub-solidus temperature range of such study, reaction between the iron and the ruby is not a problem. An area of 3 μm^2 is sampled by the spectrograph to get one pressure value; this reduces errors in pressure determination resulting from the presence of pressure gradient in the chamber. The pressure is determined at room temperature. Following the discussion by Heinz[9], a 7% decrease in the cold pressure may be made to account for the thermal pressure. Prior to measurement, a chosen spot is heated by laser to mechanically relax sample assemblage. The pressure usually drops up to 16% of the initial unrelaxed value. The pressure drop is almost linear and can be stabilized by repeated heating. The following problems are cited with the diamond-anvil cell experiments: i) reaction with the pressure medium and ii) temperature and pressure gradients. We dry the cell carefully. The corundum plate in contact with the iron does not show any visible reaction. Data on melting at high pressures show that corundum melts at higher temperature than iron at all pressures studied. We measure temperature over an area of less than 3 μm where melting was observed directly at lower pressures. It is further ascertained by the change in slope on a plot of the laser power against temperature. At high pressures (above 40 GPa) visual observations become difficult and then one must use the laser-power/temperature function and quench textures. Saxena *et al.*[10] demonstrated the accuracy of the temperature measurements by melting several solids with known melting temperatures.

In Figure 5 results of some recent experiments are displayed. The figure shows the stability of a new phase (called β by Saxena *et al.*[10]) and melting of iron to a pressure of 150 GPa by Saxena *et al.*[10]. Melting data are available to a pressure of nearly 200 GPa by Boehler[5]. The issue of the new phase is not fully resolved. It is likely that we have many additional structural modifications of iron. To begin with it is possible that the phase transformation reported by Boehler and Saxena *et al.* are for two different phases. In a recent study, by using the laser heated facilities at the Brookhaven National Laboratory synchrotron X-ray facilities, Saxena *et al.*[11] found that the hcp-iron (ε) transforms to a dhcp-iron (a four-layered hcp structure) at about 35 to 40 GPa at approximately 1500 K. This is certainly a confirmation of the possibility that we may have one or more yet unknown polymorphs of iron to be discovered.

Saxena *et al.*[10] used the new experimental data to obtain an internally consistent thermodynamic database with which to model the iron phase diagram and the core energetics. The newly generated data may then be used to calculate iron phase diagram. This combination of thermochemical and experimental data provides us with an estimation of temperature gradient in the earth's core.

Figure 6 shows the calculated phase transformations and melting in iron at pressures from 0 to 350 GPa. The extrapolation of the melting curve is done by calculating the melt compressibility as a function of temperature from the experimental data of Boehler and from this study (model 1). In such assessment of thermodynamic data, we did not include the nearly 10 to 15% error of pressure measurement possible when pressure exceeds 100 GPa (ref. 8). We generated a second model by permitting the melt compressibility to decrease at a higher rate at high temperatures by including the lower limits of the shock-wave data from Brown and McQueen[4] (see Figure 6). The high temperature melt data should be shifted to lower pressures by approximately 10%, which is quite within the stipulated random errors in the pressure measurements from the ruby fluorescence[8]. On such a melting curve (model 2), there are two triple points; the first (melt-β–γ) is located at 2946 (± 100) K and 76.5 (± 4) GPa; the second is located at 4580 K and 216 GPa insuring that the shock-wave constraint on melting[4] is satisfied. If we use the

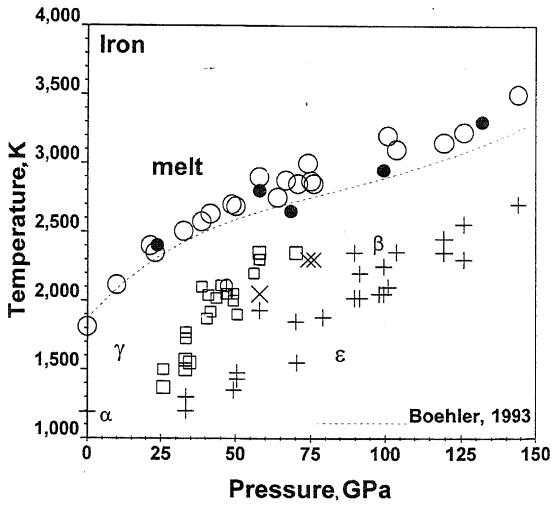

Figure 5. The experimental data on iron phase transformation and melting generated at Uppsala. The open circles represent the melting temperature determined from either visual observation or using the laser-power/temperature slope change. The size of the circles represents the error in temperature due to laser fluctuation and statistical errors of fit. The solid circles represent that iron remained solid up to that temperature. The squares represent the e–g transition and the plus sign the new phase β–ε transition. Crosses represent a phase transition which could not be labelled as either the β–γ or ε–γ.

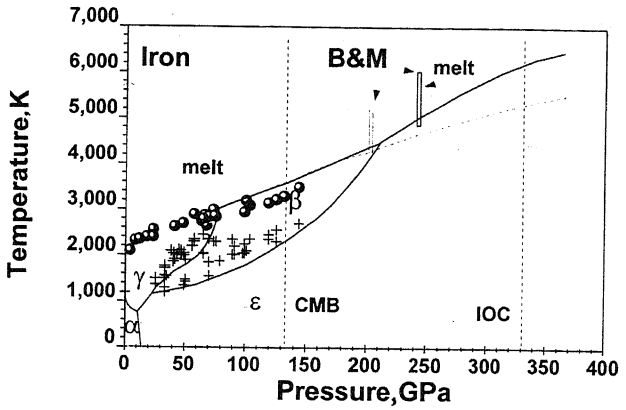

Figure 6. Iron phase diagram as calculated from the thermodynamic data from Saxena *et al.*[11]. The dashed line represents an extrapolation of the melting curve (thermodynamically calculated) with no consideration of the data by Brown and McQueen[4] (labelled as B & M). The solid line represents the preferred model and includes the consideration of the latter data within the experimental errors of pressure determination.

low-temperature limits of these data as found through model 1 which gives the second triple-point (melt-β–ε) at 4015 K and 205 GPa.

A model of the earth's core should (a) explain why the inner core is solid and the outer core liquid, (b) must use a chemical composition which is consistent with cosmochemical data and (c) be similar in density to the seismic density. We note that the answer to the first problem lies in the special melting characteristics of iron associated with phase transformations and the location of the triple point ε–β-melt. The calculated melting curves in Figure 6 show that we may expect iron melting to occur at central core pressures (363.85 GPa, PREM model[12]) between 5980 (model 1) and 6680 K (model 2). Then if we assume that the temperature in the inner core is largely adiabatic, we may start the calculation of the adiabat starting where the pure iron melting curve intersects the inner-core/outer-core seismic discontinuity. The calculated temperature (model 2) at the earth's centre is 6150 K and at the top of the inner core 6130 K. The calculated densities of ε-iron just below the melting temperatures (13.76 g mol^{-1} at 5979 K and 13.55 g mol^{-1} at 6679 K) are considerably higher than the PREM model densities. Similar conclusions led Jephcoat and Olsen[1] to suggest that the inner-core must contain a few per cent of a light component such as pyrite. A light component both reduces the density and the iron-melting temperature. To maintain a solid inner core with the appropriate PREM densities, it is sufficient to add a small amount of Mg_2SiO_4 (high pressure equivalent phases: perovskite + periclase) to ε-iron (Figure 6). Both perovskite and periclase are refractory phases, with melting temperature higher than iron[13]. At the centre, the correct density is produced when we add 1.05% solids at 6150 K. In the inner core, it was not necessary to change the composition to obtain correct densities at slightly decreasing temperatures until the geotherm meets the inner/outer core boundary at 6133 K close to iron melting at 328.85 GPa. For the geothermal gradient to change smoothly and approach the outer core and mantle boundary at ~ 4000 K, the mole per cent of solids should increase from 0.7 at the bottom of the liquid core to 1.64 at the top. For a given composition, the outer core densities do not change significantly with temperature. However, a small decrease in the amount of added solid raises the temperature significantly. With model 1, we found the inner-core temperature to vary from 5430 to 5419 K and PREM density is matched with 1.5% of solids. A little additional amount of solids (~ 1.8%) is required to match the density in the outer-core along the thermal gradient shown in Figure 6. Although Anderson[14] used different thermodynamic arguments, his calculated temperatures of 6450 K for the centre and 6210 ± 400 K for the inner and outer core boundary are quite similar to the temperatures shown here. The second model is also in general agreement with the results of Brown and McQueen[4].

The experimental iron phase diagram and the thermodynamic data result in a rather simple model for the core. The relationship between the earth and meteorites has been discussed thoroughly in the literature. The class of meteorites called irons and stony-irons are considered to be debris from differentiated broken up planetary bodies. What the present results tell us is that this picture fits the model of the earth's core very well. Thus the core has simply the same composition as the irons and stony-irons. The density from such compositions fits the seismic density well. Dilution of iron by addition of sulphur or another light element is not essential. The outer core is liquid because of the phase transformations in iron and its melting behaviour.

RESEARCH ARTICLE

Effect of micellar and microemulsion media on the oxidation of iodide by peroxodisulphate reactions

J. Santhanalakshmi and R. Kalaivani

Department of Physical Chemistry, University of Madras, A.C. College Campus, Madras 600 025, India

Water–sodium dodecylsulphate (SDS)–oil–*n*-alkanol microemulsions are constructed and used as media for I^- oxidation by $S_2O_8^{2-}$ ions. Normal SDS micelles and microemulsions in aqueous medium catalyse the self-decomposition of $S_2O_8^{2-}$ and $S_2O_8^{2-}$–I^- oxidation reactions. The overall and individual rate constants are obtained. Temperature, cosurfactant and oil effects are studied. Michaelis–Menten-type kinetics involving micelle–substrate complex equilibrium seem to describe the oxidation reaction. The E_a and ΔH variations depict the interfacial effect on substrate binding.

MICROEMULSIONS (ME) belong to a special type of surfactant assemblies in solution containing nearly monodisperse micelles or oil solubilized micellar droplets, with sizes ranging from 10 to 100 Å (refs 1,2). ME also serve as potential media for promoting compartmentalized, enzymatic, catalytic and encapsulation reactions[3,4]. In conventional ME-catalysed reactions, the micro-environments inside the droplets serve as microreactors in molecular scale for reactants solubilized in the oil or micellar cores[5,6]. Otherwise, when the dispersion medium of ME or micellar solutions serve as the reaction medium, the rate accelerations may be attributed to the presence of microdroplet or micelle spheres which create interfacial changes, excess interfacial area for substrate binding, decrease in the approachability barrier for similarly charged reactants and creation of parallel reaction of the same kind from the microemulsions and micellar surfaces, etc.[7]. Through suitable control of size of droplets, rate accelerations may be controlled and achieved through variations in the compositions of ME components, i.e. oil, water, surfactant and cosurfactant[8,9]. The oxidation reaction between iodide (I^-) and persulphate ($S_2O_8^{2-}$) ions has been chosen to monitor the ME and micellar effects because the kinetics of this reaction in aqueous medium with pH, salt and medium effects are well studied[10,11]. Since anionic reactants are involved, presence of cationic surfactants may catalyse the reaction. However, when rate accelerations are noted for anionic surfactant containing micellar and ME solutions, then ME and micellar media exemplify the concepts of micellar and ME catalysis and highlight the creation of appropriate interfaces, substrate binding, stability factors, etc.[12]. The role of microenvironments of water droplets in water in oil (W/O) aerosol OT ME on the I^- oxidation by $S_2O_8^{2-}$ has been studied[6]. Regarding oil in water (O/W) ME, however, no such study prevails. Therefore, we report here the utilization of O/W ME-containing sodium dodecylsulphate (SDS), oil, water, *n*-alkanol (cosurfactant) for enhanced rate of oxidation of I^- by $S_2O_8^{2-}$.

As cosurfactants and oil in nature form the essential parts of ME in creating the interfacial area and oil microdroplets, the effects of cosurfactant (isopropanol, *n*-propanol, *n*-butanol) and oil (benzene, toluene, xylene) are studied along with salt effect (Na_2SO_4) and activation-energy studies. Substrate binding constants on micellar and ME droplet surfaces, rate constants for $S_2O_8^{2-}$ self-decomposition and I^- oxidation are determined through kinetic principles derived in a simpler manner.

Theory

The presence of peroxo (O–O) linkage in $S_2O_8^{2-}$ anion induces easy self-decomposition to appreciable extents even under normal temperature conditions. In oxidation reactions (of I^-) involving $S_2O_8^{2-}$ anions at $T > 25°C$, fractionation of $S_2O_8^{2-}$ composition into parallel reactions, i.e. (k_d) self-decomposition and substrate oxidation (k_o) and with the separation of individual rate constants from the overall rate constant need to be analysed and when T is low, $k_d < k_o$, while T is high $k_d \geq k_o$. In presence of SDS and ME, both k_d and k_o are accelerated. k_d and k_o represent first and second order reaction rate constants. The normal mode of I^- oxidation may be considered to follow a Michaelis–Menten-type scheme since initial iodoperoxodisulphate [$IS_2O_8^{3-}$] intermediate formation is feasible due to the higher oxidation potential of $S_2O_8^{2-}$ than I^- and subsequently leads to product formation[13].

$$\text{I. } S_2O_8^{2-} \xrightarrow{k_d} 2SO_4^{2-}.$$

$$\text{II. } S_2O_8^{2-} + 2I^- \underset{}{\overset{K_o}{\rightleftharpoons}} I^- + IS_2O_8^{3-} + M \overset{K_m}{\rightleftharpoons} MIS_2O_8^{3-} + I^-$$

$$\text{(a) } \downarrow k_{20} \qquad \text{(b) } \downarrow k_{2m}$$

$$P \qquad P + M$$

where $P = 2SO_4^{2-} + I_2$; M = SDS micelle or ME droplet.

The overall kinetics of steps I and II are monitored through I_2 formation with respect to time and under pseudoconcentrations with $[I^-] = 10\,[S_2O_8^{2-}]$. Rate $= dx/dt = d[I_2]/dt = k'\,[S_2O_8^{2-}]\,[I^-]$ under pseudoconditions,

$$k'[I^-] = k;\ \text{rate} = k\,[S_2O_8^{2-}]. \tag{1}$$

Step I is first-order. Therefore at any time t, $[S_2O_8^{2-}]_t = [S_2O_8^{2-}]_o\, e^{-k\,dt}$. Hence equation (1) is

$$d\,[I_2]/dt = k\,[S_2O_8^{2-}]_o\, e^{-k\,dt}.$$

Integration between $t = 0$, $[I_2] = 0$ and $t = t$; $[I_2]$ limits gives

$$[I_2]/k\,[S_2O_8^{2-}]_o = (1 - e^{-k\,dt})/k_d$$

$$= (e^{k\,dt} - 1)/k_d\, e^{k\,dt}. \tag{2}$$

Expansion of $e^{k\,dt}$ series, neglecting t^2 powers, etc., the RHS of equation (2) becomes

$$k\,[S_2O_8^{2-}]_o/[I_2] = k'[I^-]_o\,[S_2O_8^{2-}]_o/[I_2] = 1/t + k_d. \tag{3}$$

Thus, applying linear regression on $[I^-]_o[S_2O_8^{2-}]_o/[I_2]$ against $1/t$, values of $k = 1/\text{slope}$ and $k_d = k'x$ intercept are obtained. Likewise, k_d in presence and absence of SDS, and ME may be derived. From known k_d values, fraction $[S_2O_8^{2-}]$ decomposed in t is known and the remaining fraction of $[S_2O_8^{2-}]$ contributes to the oxidation reaction. In normal reaction, the overall rate constant of oxidation reaction (k') may be considered as k'_o, and as k'_m in presence of SDS and ME. Thus second order rate of II(a) reaction will be

$$\text{vII(a)} = k'_o\,[S_2O_8^{2-}]\,[I^-]. \tag{4}$$

In terms of the reaction scheme,

$$\text{vII(a)} = k_{20}\,[I^-]\,[IS_2O_8^{3-}] \tag{5}$$

$$= \frac{k_{20}\,K_o\,[I^-]^2\,[S_2O_8^{2-}]}{1 + K_o\,[I^-]},$$

where

$$K_o = \frac{[IS_2O_8^{3-}]\,[I^-]}{\{[S_2O_8^{2-}] - [IS_2O_8^{3-}]\}\,[I^-]}$$

comparing equations (4) and (5)

$$k'_o = \frac{k_{20}\,[I^-]\,K_o}{1 + K_o\,[I^-]}$$

which can be rearranged as

$$1/k'_o = \{1/k_{20}K_o\,[I^-]\} + 1/k_{20}. \tag{6}$$

In presence of micelles and ME, a fraction of $[IS_2O_8^{3-}]$ formed $[F_o]$ will be partitioned towards micelle association $[M\text{–}IS_2O_8^{3-}]\,[F_m]$, resulting in micellar catalysis through concomitant reactions II(a) and II(b). The contributions of $[IS_2O_8^{3-}]$ and $[M\text{–}IS_2O_8^{3-}]$ on k'_m may be written as

$$k'_m = F_o\,k_{20} + F_m\,k_{2m} \tag{7}$$

where fractions

$$F_m = \frac{[M\text{–}IS_2O_8^{3-}]}{[IS_2O_8^{3-}]};$$

$$F_o = \frac{[IS_2O_8^{3-}] - [M\text{–}IS_2O_8^{3-}]}{[IS_2O_8^{3-}]} = 1 - F_m$$

$$k'_m = k_{20} + F_m(k_{2m} - k_{20}).$$

Also

$$K_m = \frac{[M\text{–}IS_2O_8^{3-}]}{[S_2O_8I^{3-}]\,[M]}$$

and

$$K_m = F_m/[M].$$

Rearrangement leads to

$$\frac{k'_m - k_{20}}{k_{2m} - k_{20}} = K_m\,[M]$$

$$= K_m\,[CD - CMC]/N, \tag{8}$$

where CD = surfactant concentration; CMC of SDS = 1.35×10^{-3} mol dm^{-3}; N = SDS micelle aggregation number = 95.0 (ref. 12).

Also

$$\frac{k'_m - F_o k'_o}{F_m} = k'_m,$$

and

$$\frac{1}{k'_m} = \frac{1}{k_{2m}\,K_m\,[I^-]} + \frac{1}{k_{2m}}. \tag{9}$$

The double reciprocal plot equations (6) and (9) ($1/k'_o$ or $1/k'_m$ vs $1/[I^-]$) can be used to determine (k_{20}, K_o) and (k_{2m}, K_m) values.

The extent of micelle/ME catalysis depends on the $[M\text{–}IS_2O_8^{3-}]$, which depends on the available number of free ion-binding sites on the stern layer of the micelle/ME. If the fraction of Na^+ counterion bindings per micelle is $(1 - \alpha)$, then α will be the fraction of

free sites per micelle. Also α equals $[M\text{–}IS_2O_8^{3-}]/[M]$, using K_m and K_o expressions, α can be expressed as $\{K_mK_o[I^-][S_2O_8^{3-}]\}$. At constant $[I^-]$, $[S_2O_8^{2-}]$, α values for normal, and in presence of SDS, ME with various alkanols and oils may be obtained and compared. The catalytic activity coefficient β^{-1} equal {vII(b)/vII(a)} which equals $(k_{2o}/k_{2m}) \cdot \alpha/K_m \cdot K_o$ may be obtained.

Experimental

Materials

SDS, $K_2S_2O_8$, KI, $Na_2S_2O_3$ (Lobachemie) and starch (E Merck) were used as such. Benzene, toluene, xylene (E Merck) were distilled fresh before use.

Kinetic measurements

The kinetics were followed by measuring the clock time of appearance of blue colour (I_2 generation) from the mixture containing KI, $K_2S_2O_8$, $Na_2S_2O_3$, and starch; and SDS or ME if necessary[14]. The reactants were N_2 purged and thermostated at desired temperature. The reaction time commenced from the addition of $K_2S_2O_8$.

Microemulsion preparation

To an aqueous solution of SDS, the oil for 5% of H_2O was added and the turbid solution was titrated with constant stirring against the *n*-alkanol taken in a microburette until transparency was reached. The pseudo-ternary phase diagrams encompassing the oil in water microemulsion region correspond to the percentage compositions of the microemulsion constructed. The phase boundaries are checked by preparing above and below compositions and tested for ME properties. ME medium was N_2 purged and the weighed quantities of the clock reaction components were added and the time of appearance of I_2 was noted.

During the reaction time, ME were found stable and no phase separation resulted. Changes in oil and cosurfactant nature were monitored by adding the respective components and maintaining the similar conditions. During oxidation reactions, alcoholic oxidation did not occur.

Electronic spectra of pure SDS, KI, $K_2S_2O_8$ solutions and mixture of KI and $K_2S_2O_8$, KI + $K_2S_2O_8$ + SDS are recorded in a UV Specord Carl Zeiss Spectrometer in the 200 to 350 nm range.

Results and discussion

Figure 1 shows pseudoternary phase diagram of benzene, toluene and xylene containing SDS–water–*n*-alkanol microemulsions. Xylene produces extended L_1 microemulsion boundaries than benzene and toluene. Higher solubilization of xylene may be accounted for branched cosurfactant like isopropanol. Generally higher solubilization causes interfaces with higher extent of fluidity, lower extent of counterion binding and higher substrate association.

Table 1 gives the phase compositions of four components of oil/water ME employed in the kinetics. The compositions fall within the ME domains in the pseudo-ternary phase diagram of O/W regions (Figure 1). During the study of salt effect, there is no phase separation in these formulations due to the low concentration of the salt and possibly due to the counterion-binding effects of the double layer.

Table 2 gives the overall pseudo-first-order rate constant values (k) at different [substrate] under normal, micellar and ME conditions. Increase in T increases k' values. Separate rate constants for $S_2O_8^{2-}$ decomposition (k_d) and I^- oxidation (k_o'), determined using equation (3) and Figure 2 for the uncatalysed and catalysed reactions, are given in Table 3. The linear fits of double reciprocal plots given in Figure 4 [equation (6) and equation (9)] are used to determine the values of (k_{2o}, K_0) and (k_{2m}, K_m) for the I^- oxidation process in absence and presence

of micelles and microemulsions. These values are given in Table 4. The effect of surfactant concentration on k_m is shown in Figure 3. Even though rate constant values are altered, the orders of the parallel reactions (first order decomposition and second order oxidation) remain unaltered in presence of micelles/ME.

Study of the rate constant values shows some salient features: addition of Na_2SO_4 enhances the overall rate constant in accordance with the ionic strength effect on ionic reactions containing the same sign ions[15]. SDS in aqueous solution may be considered to act as 1 : 1 electrolyte below its CMC. As the concentration of SDS increases while approaching its CMC value, grouping of dodecylsulphate anions for the purpose of micellization occurs. This process causes a sudden depletion of the

anions and lowering of ionic strength around the CMC value which may bring in a slight decrease in the rate near the CMC. With further increase in surfactant concentration, the number density of micelles increases and micellar catalysis ensues. Therefore the rate starts increasing from CMC (Figure 3). The creation of appropriate interfaces due to micelles or microemulsion enhances the substrate interfacial bindings and decreases the approachability barrier between similarly charged substrates. Here, this effect is more pronounced, since binding cum exchange of sulphate ions of $S_2O_8^{2-}$ in the medium and the sulphate ions of the SDS micelle stern layer is more probable[16]. If it is so, the micelle/ME-interfacially associated substrate/intermediate would probably create a concomitant similar to the normal reaction.

In the phase components belonging to outside boundary and falling within the bicontinuous phase or any other heterogenous phase lowers the rate due to impeding effect of the other phases. When other compositional variation that lead to other phase changes like bicontinuous microemulsions is tried for reaction media, the

reactions exhibited low rates and the reactivity difference may be due to the structural variation in surfactant assemblies in solutions. In these compositions, the heterogeneity is more due to the higher compositions of O/W ME. So, one may say that there is a decreased reactivity of the reactants in other regions compared to O/W microemulsions.

The values of k_d and k_o' are observed to be accelerated in presence of SDS and microemulsions. In all instances, I^- oxidation seems faster than $S_2O_8^{2-}$ decomposition, since high energy peroxobond needs to be dissociated in the decomposition step.

The UV spectroscopic evidence was sought to visualize the formation of M–$IS_2O_8^{2-}$. When the spectra of separate solutions of SDS, KI, $K_2S_2O_8$ are compared with that of the mixture containing micelle, I^-, $S_2O_8^{2-}$, then the characteristic λ_{max} of $S_2O_8^{2-}$ seems to have shifted. The shift is significant when compared with pure SDS micelles towards red shift. This can be attributed to the interfacial substrate binding. However, this peak variation

Scheme 1.

with time could not be monitored and approaches as (2). This spectrum (4) was obtained instantaneously after mixing.

The extent and the stability of the substrate association with the micelle/ME interfaces are reflected from association constant values (K_o, K_m). $K_o > K_m$ trend indicates that presence of SDS/ME aid the decomposition of the intermediate by forming a lesser stable complex. Lower K_m values are also due to the lesser probability of binding of anionic intermediate on anionic SDS micelle interface. However concomitant fractionation of $IS_2O_8^{3-}$ to $M–IS_2O_8^{3-}$ leads to an overall acceleration of the rate. The interfacial interactions are shown in scheme 1.

Regarding microemulsions, solubilization of small proportions of oil occurs at hydrophobic micellar core, resulting in oil-swollen micelles. Addition of cosurfactants may sometimes result in further fractionation of droplets. In any case there is an excess interfacial area created during microemulsification. This effect increases the fraction of free ions at the stern layer of the micelle and the oil-swollen micelle. Therefore interfacial association of the substrate increases. Also, due to the enhanced interdroplet interactions, certain amount of instability prevails on the $[M–IS_2O_8^{3-}]$. The presence of cosurfactants tends to lower the extent of micellar catalysis since the cosurfactant molecule adheres competitively at the interface. Due to a considerable reduction in the interfacial effect, $k_{2m} < k_{20}$ is noted. With increase in the carbon chain length of the cosurfactant, k_{2m} values are lowered. The overall k values increase from benzene, toluene and xylene while k_d values suffer a decrease since phase separation of ME occurred occasionally, the data remain nil in such cases.

In ME the fraction of free micellar ionic sites increases, i.e. α-values increase in ME (Table 5). β^{-1} values measure the extent of catalysis and the role of interfacial effect. Even though α increases, β decreases in certain cases due to the resistance offered by the cosurfactant on the $M–IS_2O_8^{3-}$ product conversions.

Increase in temperature increases the k, while K decreases. The thermal effects induce instability of the associated complex due to competitive desorption of the substrate from the interface. But due to the lowering of K values, k_{20} and k_{2m} values increase, i.e. instability of the associated intermediate is removed through conversions leading to products. The E_a and ΔH values of the catalysed and normal reactions show negative values when an increase in temperature decreases the k and K values. This effect is large in case of ME. The ΔH values of the normal and ME media are comparable while that of SDS is more. The close packing of the surfactant molecule in the aggregates is loosened in the ME due to the presence of cosurfactants and oil inclusions. Also, micelle and ME droplet breakdown processes prevail when T increases.

Thus creation of interfaces inside the bulk medium through the presence of micelles or ME certainly induces acceleration of the decomposition and the iodide oxidation processes of $S_2O_8^{2-}$ ions. The separation of the rate constants of the individual step from the overall values applies for the normal and micelle/ME media. However, the collisional and diffusional properties of micelles and ME stand to be probed for future studies.

Some FRW models with constant active gravitational mass

Abdussattar and R. G. Vishwakarma

Department of Mathematics, Banaras Hindu University, Varanasi 221 005, India

The consequences of taking the active gravitational mass of the universe constant in the background of FRW models are investigated. It is found that the dependence of the nature of expansion on the curvature parameter k may be altered.

IN the standard big bang cosmology, wherein the universe is assumed to be filled with a distribution of matter represented by the energy momentum tensor of a perfect fluid

$$T_{ij} = (\rho + p)v_i v_j + p g_{ij}, \quad \text{(in the units with } c = 1) \qquad (1)$$

and the geometry of the universe is described by the Robertson–Walker line element

$$ds^2 = -dt^2 + R^2(t)\{(dr^2/1 - kr^2) + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)\}, \quad k = \pm 1, 0, \qquad (2)$$

the Einstein field equations

$$R_{ij} - \tfrac{1}{2} R_h^h\, g_{ij} = -8\pi G T_{ij} \qquad (3)$$

obtain two independent equations

$$-\ddot{R}/R = (4\pi G/3)(\rho + 3p), \qquad (4)$$

and

$$\dot{R}^2/R^2 + k/R^2 = (8\pi G/3)\rho. \qquad (5)$$

The expression for the scale factor R is obtained by solving the differential equation resulting from equations (4) and (5) by assuming an equation of state. Out of the three cases of the model obtained for different values of the curvature parameter k, one is closed for $k = +1$ and the remaining two are ever expanding for $k = 0$ and -1. In this communication, motivation is given for taking the active gravitational mass of the universe as constant and it is found that the dependence of the nature of expansion of the resulting models on the curvature parameter k may be different from that of the standard models.

The field equation (4) may be deemed as an analogue of the Newtonian force law and suggests that the force per unit mass at each space-time point is determined by the active gravitational mass density $(\rho + 3p)$. Here we note that the gravitational pull is exerted not only by ρ as in the Newtonian theory but rather by $(\rho + 3p)$ which exhibits a relativistic effect. It is this additional pressure and internal energy contribution to the gravitational force which is the major cause of the problem of gravitational collapse in general relativity[1].

One notes that equations (4) and (5) obtain $\rho R^3 = $ constant (ref. 2) in the present pressureless phase of evolution, which can be interpreted as the conservation of the total active gravitational mass of the comoving sphere of radius R. As there is no justification of conferring a special status upon the present epoch, we speculate that this constancy feature of the active gravitational mass is met not only in the present phase of evolution but in the early phases too. We thus assume that in the presence of pressure, the active gravitational mass is constant.

$$(\rho + 3p)R^3 = \text{constant} = A \quad \text{(say)}. \qquad (6)$$

Equation (6), taken together with the energy momentum conservation equation

$$\dot{\rho} + 3(\rho + p)\, \dot{R}/R = 0\,, \tag{7}$$

which may be obtained from equations (4) and (5), leads to

$$p^3 = K(\rho + 3p)^2, \quad K = \text{constant} \geq 0\,, \tag{8}$$

which is the equation of state for the perfect fluid constituting the matter content of the universe. It is a physically reasonable equation of state since

$$(dp/d\rho) = [2/3 \cdot (p/(\rho + p))]\,, \tag{9}$$

indicating that $(dp/d\rho) < 1/3$ for $\rho > p$.

Equations (4) and (6) obtain

$$\ddot{R} = -(4\pi GA/3R^2)\,, \tag{10}$$

which, by integrating, gives

$$\dot{R}^2 = (8\pi GA/3R) + B\,, \tag{11}$$

where B is some constant of integration. Equations (5), (6) and (11) may be used to obtain

$$\rho = A/R^3 + 3(B + k)/8\pi GR^2 \tag{12}$$

and

$$p = -(B + k)/8\pi GR^2\,, \tag{13}$$

which are in agreement with equation (8) and suggest that $K = -(B + k)^3/(8\pi G)^3 A^2$ for the self-consistency of the system.

Equation (13) indicates that in order to have $p \geq 0$, one must have $(B + k) \leq 0$.

We note from equation (6) that for $\rho > 0$ and $p > 0$, $A > 0$. Equation (10) hence indicates that $\ddot{R} < 0$. This, together with $\dot{R} > 0$, implies that the curve $R(t)$ must have reached $R(t) = 0$ at some finite time in the past, say at $t = 0$, which is a singularity, where equation (6) holds in the limiting case. The models thus start from a big bang.

Equation (11) may be integrated for different values of k as:

$k = 0$

We thus have $B \leq 0$ for $p \geq 0$. When $B < 0$ say $B = -n^2$, we obtain

$$t = -\frac{(24\pi GAR - 9n^2R^2)^{1/2}}{3n^2} + \frac{4\pi GA}{3n^3} \times \sin^{-1}\left[\frac{3n^2R}{4\pi GA} - 1\right] - \frac{2\pi^2 GA}{n^3}\,. \tag{14}$$

When $B = 0$, we have

$$R = (6\pi GA)^{1/3}\, t^{2/3}\,. \tag{15}$$

Equation (14) indicates that the model reaches its maximum radius $R_{max} = 8\pi GA/3n^2$ at $t = 4\pi^2 GA/3n^3$ and thereafter starts contracting back to origin in a way similar to the $k = 1$ case of the standard model though here $k = 0$. Equation (15) suggests that $R \to \infty$ as $t \to \infty$ with the deceleration parameter $q = \frac{1}{2}$ always as in the $k = 0$ case of the standard model.

$k = -1$

In this case $p \geq 0$ demands $B \leq 1$. If $B > 0$, say $B = n^2 \leq 1$, we obtain

$$t = \frac{(24\pi GAR + 9n^2R^2)^{1/2}}{3n^2} - \frac{4\pi GA}{3n^3} \times \cosh^{-1}\left[\frac{3n^2R}{4\pi GA} + 1\right]\,, \tag{16}$$

which indicates that $R \to \infty$ and $\dot{R} \to n$ as $t \to \infty$. The deceleration parameter, which is initially $\frac{1}{2}$ in this case tends to zero as $t \to \infty$. For $B \leq 0$, the evolution is described by equations (14) or (15).

$k = 1$

In this case, $p \geq 0$ demands $B \leq -1$ and the evolution is governed by equation (14) which describes a closed universe as mentioned earlier.

We thus see that the dependence of the nature of expansion on the curvature parameter k may be altered by the incorporation of the conservation law (6) in the standard cosmology.

Evaluation of intra-specific variability in *Avicennia marina* Forsk. using RAPD markers

P. Balakrishna

M.S. Swaminathan Research Foundation, Madras 600 113, India

Random amplified polymorphic DNA (RAPD) markers for determining the genetic diversity among Mangrove species, *Avicennia marina* Forsk. were used. Individuals collected from several sites in India were analysed for their genetic relationship. Both inter- and intra-populational level polymorphisms were observed. The dendrogram arising out of the RAPD data shows prominent patterns of relationships that are discussed in the light of the respective habitats of the species distributed in India. The usefulness of RAPDs in biodiversity assessment and evaluation has therefore been tested.

UNDERSTANDING the genetic basis of diversity of plants helps utilize plant genetic resources effectively. Because of the long-term life cycle, tree genetics tends to receive less attention than annual crops. Among tree species, mangrove forest trees have not so far been subjected to detailed genetic analysis. Mangroves form an important group of plants for several of their characteristics, including their ability to withstand high levels of salinity, besides protecting coastal areas from seawater intrusion[1]. However, this group has suffered from lack of information on their genetics. They are distributed all over tropics and 59 species belonging to 29 families occur in India. Mangrove habitats now face serious threat due to extensive felling, changing coastal environment including lack of freshwater inflow[2]. The performance of each species differs in such an environment and differences are apparent[3]. Conservation of mangroves is thus a major priority in coastal area development. Of several cosmopolitan species of mangroves, *Avicennia marina* is an important species because it can withstand varying soil conditions, high levels of salinity, lack of freshwater inflow for considerable periods of time and pollution of varying forms[4]. Besides they have good rates of regeneration and show different adaptational features. Genetic characterization of mangroves is unfortunately limited owing to lack of concerted studies on identifying the genetic variability within and in-between species. There is no report on the genetic diversity of mangroves except for *Rhizophora* species[5]. Though isozyme studies have been carried out in mangroves their reproducibility is rather poor.

Genetic analysis of tree species, especially of forest trees, has not received much attention from molecular biologists until recently. Relatively few genetic maps are available for forest trees[6–8]. This is mainly due to lack of suitable pedigrees and basic genetic data like number of chromosomes, linkage groups and even population genetic analysis.

Mangroves are threatened all over the world today due to direct and indirect exploitation. Conservation of mangroves has thus become important not only to protect the coastal areas but also to protect the coastal communities from seawater intrusion and from the adverse impacts of potential changes in sea level rise. One of the suggestions for mangrove restoration is to select genetically superior germplasm and to introduce them into target sites[9]. But for this to happen it is important to understand the extent of diversity in individual species and the relationship these species have with their respective habitats. Diversities in structural formations of mangrove ecosystems can be witnessed along the latitudinal and longitudinal gradients. This may be due to the climate or soil or due to water availability[10]. Thus there is a necessity to evaluate the genetic diversity of these trees.

Random amplified polymorphic DNA (RAPD)[11] markers have been successfully used to assess the genetic diversity within several groups of plants, including tree species like conifers, Norway spruce, pine and others[12–14]. Besides this, RAPDs were also used for several other purposes like genome mapping, population genetics, introgression analysis[15]. RAPDs are better choice of markers for evaluation of genetic diversity in species where cloned markers are not available. Hence RAPD analysis was undertaken in mangrove species, *A. marina* which showed clear inter- and intra-populational variability from the collections made in India. The sites selected were from different habitats ranging from unpolluted Pichavaram to polluted sites like Ennore with petrochemical pollution and Adyar with inorganic pollution. Duplicate samples were collected from Ennore and Bombay so that they can represent the trueness of the genetic analysis. Genetic correlations and genetic distance analysis were done using RAPD data to relate them with the habitat and growth.

A. marina accessions were collected from different sites in India (from Bombay, Ganapatipule in Maharashtra, Pichavaram in Tamil Nadu, Ennore and Adyar in Madras). Seven accessions representing five locations were chosen to see if the RAPD markers were useful to study their genetic diversity. For detecting the variations a total of 25 primers were initially used, out of which 12 gave diagnostic polymorphisms of inter- and intra-populational variability.

Total genomic DNA was isolated from lyophilized leaf material. To 300–400 mg of powdered leaf tissue, 1000 µl of extraction buffer (1 M Tris-HCl, pH 8.0, 5 M NaCl, 0.5 M EDTA, 14 β mercaptoethanol, and 1% CTAB) was added and incubated at 65°C for 90 min with occasional mixing. The mixture was then cooled

to room temperature and 500 µl of chloroform : octonol (24 : 1) was added. After centrifuging at 10,000 rpm at 4°C for 10 min the supernatant was transferred to a fresh tube. To this 750 µl of ice-cold isopropanol was added. The DNA was washed with 500 µl of 70% ethanol and 750 µl of 3 M sodium acetate and again with 70% ethanol. The DNA was then air-dried and suspended in 1X TE buffer.

Decamer oligonucleotide primers were used in this study. Table 1 lists primers that were selected for the final analysis. Amplifications were done in volumes of 25 µl containing 10 mM Tris-HCl, pH 8.3, 50 mM KCl, 1.5 mM $MgCl_2$, 0.1 mM each of dATP, dTTP, dGTP, and dCTP (Perkin Elmer, USA), 5 ng of genomic DNA, 0.5 µM of primer and 3 units of *Taq* DNA polymerase (Perkin Elmer, USA). The amplification was carried out on a Perkin Elmer 480 thermal cycler (Perkin Elmer, USA). Samples were amplified at one step of 2 min at 94°C, 40 repeats of the following cycles—one min at 94°C, one min at 37°C, two min at 72°C, and then a final extension time of 4 min at 72°C. The amplified products were then analysed on 1.8% agarose gels stained with ethidium bromide.

For each primer, bands were scored for their presence (+) or absence (–) of a amplified product. From these data a simple matching coefficient (SMC) analysis was carried out on a GENSTAT 5 program (licensed to Lawes Agricultural Institute, UK) to analyse the genetic distance and genetic relatedness. SMC takes into account the entire amplification products from various genotypes under study against all the primers scored for. Thus weightage is given as a shared presence or absence of bands also in calculating similarities and distance of different genotypes.

Table 1. List of amplification products generated by using arbitrary 10 base oligonucleotides, based on all accessions

Primer	Sequence	No. of fragments detected: within *A. marina*	No. of fragments detected: between *A. marina*
1.	3′ GTTTCGCTCC 5′	35	19
2.	3′ TGATCCCTGG 5′	14	14
3.	3′ CATCCCCCTG 5′	27	16
4.	3′ GGACTGGAGT 5′	22	13
5.	3′ TGCGCCCTTC 5′	21	12
6.	3′ CCATTCCGAG 5′	2	2
7.	3′ CACCTGCTGA 5′	17	4
8.	3′ GTGAATGCGC 5′	4	1
9.	3′ CCTACACGGT 5′	15	5
10.	3′ CAGCCGAGAA 5′	11	3
11.	3′ GAAGGAGGCA 5′	21	8
12.	3′ TGAACCGAGG 5′	16	6

Isolation of DNA from Mangrove species has been a difficult problem until now. This is because they contain a number of secondary metabolites like phenolics, terpenoids, alkoloids and mucilage. The DNA extraction protocol followed here solved this problem. Of the 25 primers screened, 12 were found to be suitable for diagnosis. Amplified products could be detected from all primers used. A total of 205 amplified products were scored. Within an individual plant the primers detected RAPD patterns containing DNA bands within 0.1 to 2.3 kb.

Except for primer 4 (Table 1) all the others gave good variability profiles. Primer 4 was not able to detect

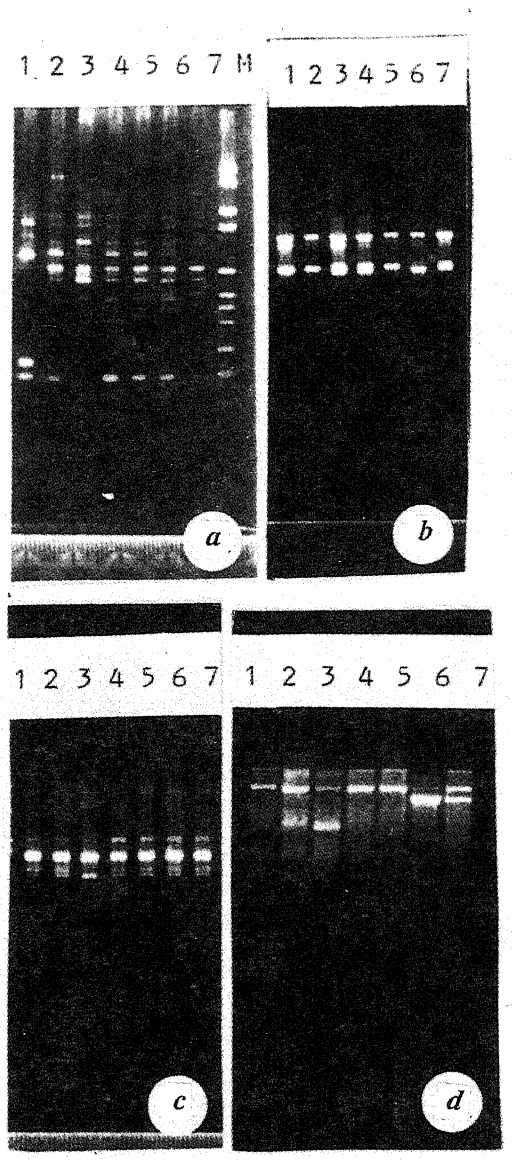

Figure 1. Example of amplified products from *A. marina* populations collected from: Lanes 1 & 2, Bombay; 3, Ganapatipule; 4, Pichavaram; 5, Adyar; 6 & 7, Ennore. ***a***, Amplified products using primer 3′ GTTTCGCTCG 5′; ***b***, Amplified products using primer 3′ TGATCCCTGG 5′; ***c***, Amplified products using primer 3′ CATCCCCCTG 5′; ***d***, Amplified products using primer 3′ GGACTCCAGT 5′.

any variation within the samples. This polymorphism was apparent with all the primers and was not only between samples but also within the samples collected from different sites (Figure 1). The dendrogram constructed based on the SMC analysis and represented in Figure 2 distributes the genotypes into different clusters. The amount of variability detected when the DNA sample was subjected to repeated RAPD analysis was the same, confirming the reproducibility of the analysis.

The two sites selected each in Ennore and Bombay showed considerable variations (Figure 1). All the primers except primers 4 and 8 detected variations within these sites and the dendrograms showed their relatedness (Figure 2). Genetic distance map was also constructed based on the RAPD data using SMC (Figure 3) to identify the distances. It was found that all the genotypes were distinctively different and separate based on amplified products.

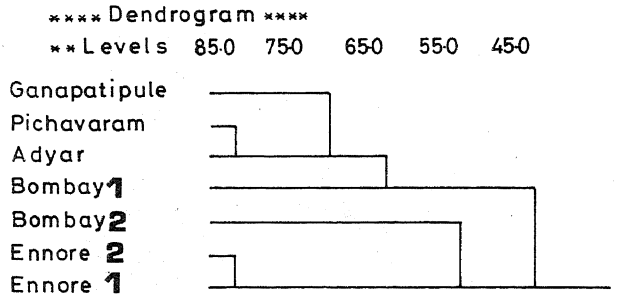

Figure 2. Dendrogram showing genetic relationships between *A. marina* populations constructed using simple matching coefficient analysis based on RAPD analysis.

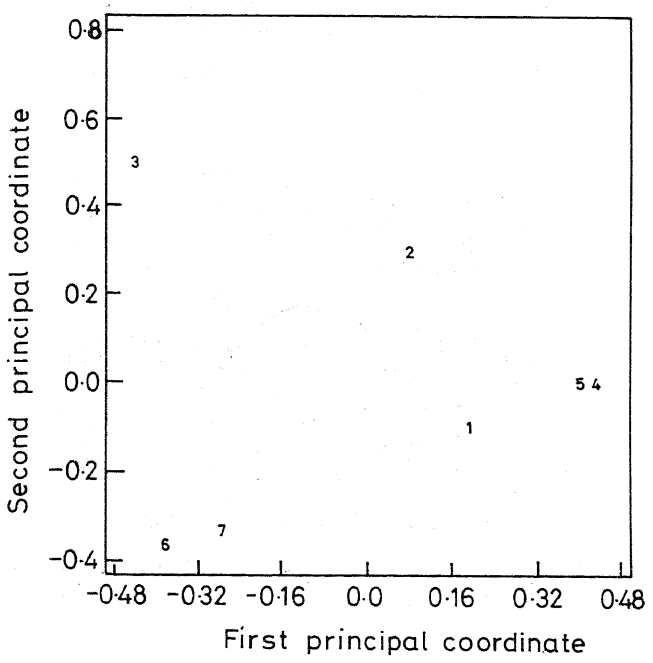

Figure 3. Genetic distance analysis of *A. marina* revealed by RAPD markers and analysed using simple matching coefficient analysis. 1 & 2, Populations from Bombay; 3, Ganapatipule; 4, Pichavaram; 5, Adyar; 6 & 7, Ennore.

With an aim to understand the genetic diversity and the relatedness of mangrove species, *A. marina* was taken as a model. This is because of its several and varied adaptational and distributional patterns. RAPD was analysed on seven populations and the variability patterns were scored on the basis of amplified products. The analysis was carried out not only on a pairwise combination of variability but also accounted for the entire information given by all the genotypes against all the primers used. This comparison is based on the presence or absence of a band (amplified product) and give weightage as a shared presence in calculating similarities[16].

The distribution of the genotypes observed on the dendrogram is represented in Figure 2 and shows that the RAPD data can be a powerful tool in assessing the genetic diversity. With regard to intra-site variability, there is variability within *A. marina* collected from the same sites. This is surprising because the species have evolved from the same habitats for a long period of time. The frequent inundation of seawater might have helped cross pollination to account for this polymorphism. Though the dendrogram is quite revealing the groups are considered different with respect to sites. The similarity between the material collected from Bombay and Ennore may be due to similarities in soil conditions like hypersalinity and the type of pollution[17]. Ganapatipule and Pichavaram are considered to be reasonably less polluted and also received copious amounts of freshwater inflows, while Adyar falls between these two groups. This relatedness is also established in the genetic distance and similarity analyses.

The RAPD technique contributes to a better understanding of genetic characterization than the analysis of isozymes. For developing conservation methodologies it is important to evaluate the genetic diversity within a given species. Intra-populational level variation helps to identify suitable genetic material also. This kind of data *vis-à-vis* the other physiological, edaphic factors are taken into account when identifying suitable clones for introduction into different areas. Also, this study proves the utility of RAPDs in biodiversity measurement.

Carbon and oxygen isotope trends in late Precambrian–Cambrian carbonates from the Lesser Himalaya, India

B. Kumar and V. C. Tewari*

National Geophysical Research Institute, Hyderabad 500 007, India
*Wadia Institute of Himalayan Geology, Dehradun 248 001, India

$\delta^{13}C$ and $\delta^{18}O$ records of the Late Precambrian–Cambrian (Pc–C) carbonates from the Lesser Himalaya are reported here. The data depict two distinct cycles of ^{13}C maxima–minima and one distinct ^{18}O maxima for these carbonates. We suggest that isotopic variations across Pc–C stages relate to marked changes in the carbon and oxygen fluxes.

CARBON isotope signatures of the Precambrian–Cambrian boundary carbonates have been studied from a number of localities of the world[1–6], but their implications are still controversial. The preservation of original $\delta^{18}O$ records[3] in Pc–C boundary carbonates has also been questioned. We present here the result of a carbon and oxygen isotope study of two marine carbonate successions of Late Precambrian–Cambrian age from the Lesser Himalaya. The isotopic data are evolved in relation to sedimentary carbon budget and atmospheric oxygen level (?) changes etc.

In the northwestern Himalaya, two major carbonate-bearing successions, namely, the Deoban Formation of Lower to Middle Riphean age and the Krol Formation of Late Vendian (Ediacaran) age are present[7–9] (Figure 1). The Deoban Formation contains an approximately 1000 m thick succession of carbonate rocks (stromatolitic dolomites, dolomitic limestones, cherty limestones an oolitic limestones) with intercalated beds of shales. It is followed by a shallow marine sequence of the argillo-siliciclastic deposits known as the Simla/Jaunsar Group which comprises of Mandhali, Chandpur and Nagthat formations. The Simla/Jaunsar Group is overlain by the Blaini Formation of early Vendian (Varanginian) age, consisting of diamictite beds and minor deposits of microbial dolomites, siltstones and shales. The Krol Formation of Vendian age includes an ~2000 m thick succession of stromatolitic dolomites, cherty limestones, shales, sedimentary breccia, oolites and grainstones. It

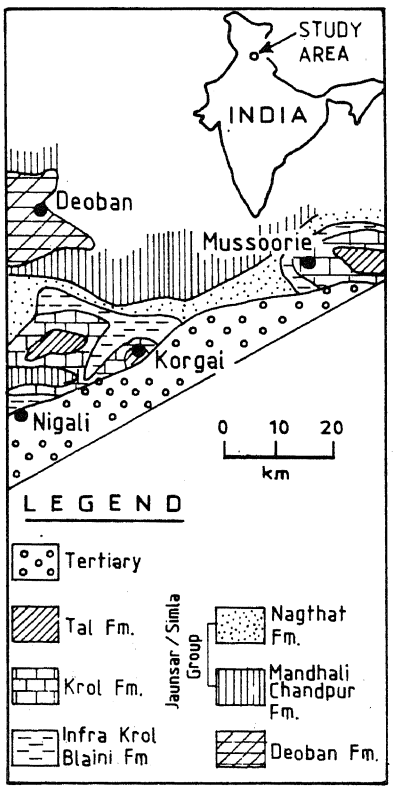

Figure 1. Geological sketch of the Deoban, Blaini and Krol–Tal sedimentary succession of the Lesser Himalaya, showing location of the study area. (map after Chaudhri and Kaltia[22]).

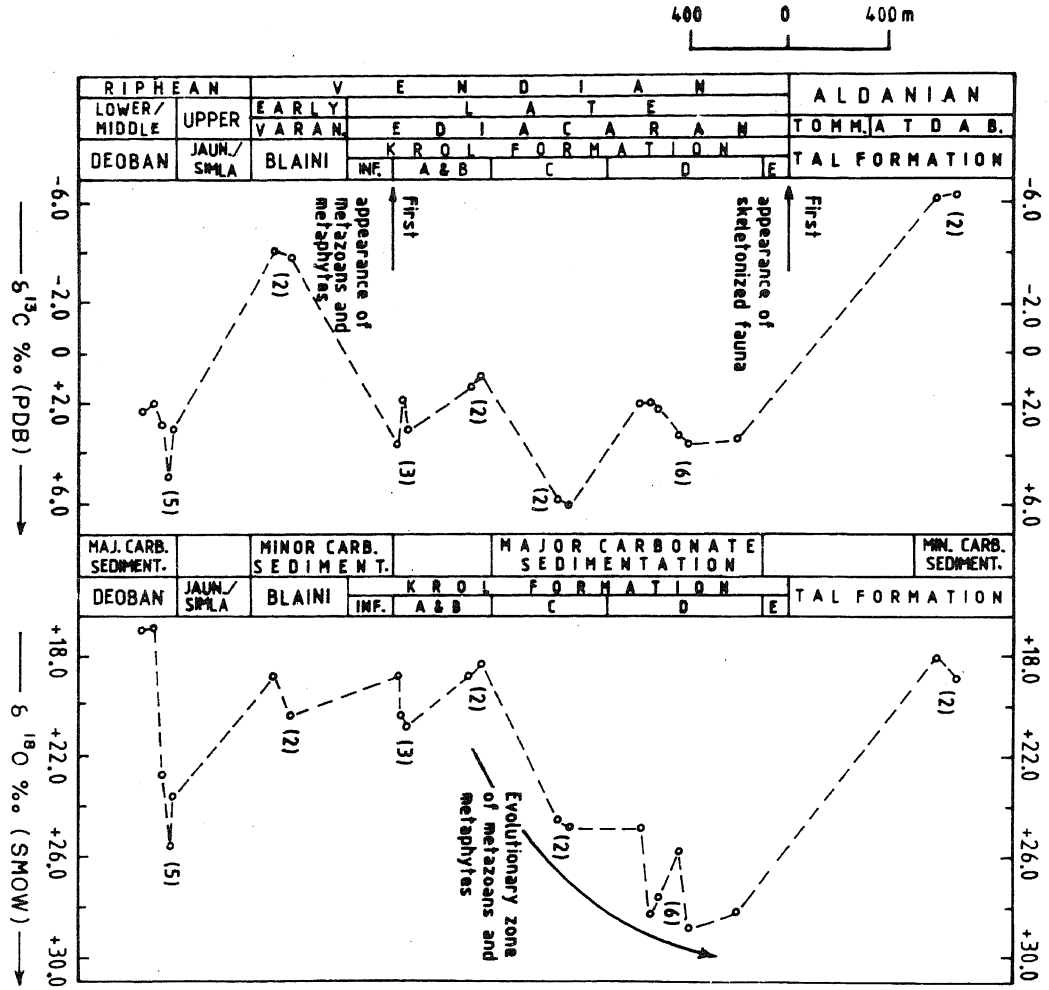

Figure 2. $\delta^{13}C$ and $\delta^{18}O$ records of the Deoban, Blaini, Krol and Tal carbonates in relation to their stratigraphy (the numbers in the bracket refer to number of samples analysed from each formation).

is followed by the Tal Formation (Early Cambrian) which consists of a Chert Phosphorite Member of Tommotian age and argillo–calcareous and siliciclastic member of Atdabanian–Botomian age. The carbonate sedimentation in the Tal Formation is minor. A late Precambrian to early Cambrian age for these formations has recently been established by biostratigraphic studies based on: i) discovery of microfossils of Late Precambrian age[7]; ii) identification of stromatolites of Late Precambrian affinity[8,9]; iii) documentation of Ediacaran metazoans and metaphytes[10,11] in the Lower Krol Member; and iv) records of the early Cambrian small shelly fauna[12,13], trilobites[14], brachiopods[15] and trace fossils[16].

The carbonates investigated in this study have been sampled from the Deoban Formation developed in the Deoban Mountains (30°45′ 77°54′) and those from the Blaini, Krol and Tal formations in the Korgai and Nigalidhar synclines (30°34′50″, 77°39′15″, cf. Figure 1).

$\delta^{13}C$ and $\delta^{18}O$ trends of the Deoban, Krol and Tal carbonates are plotted in Figure 2 in relation to stratigraphy of these carbonates. The isotope trends are drawn through the 'δ' values. $\delta^{13}C$ values become generally more positive from the Middle Deoban reaching ^{13}C maximum of +4.9‰ (PDB) in the Upper Deoban. This is followed by a decline of ^{13}C to a minimum of –4‰ in the Blaini. The carbon isotope profile shows a second rise in the Krol-C depicting a ^{13}C maximum of +6‰ which drops to a minimum of −6.2‰ within the Tal. $\delta^{18}O$ varies from +17.2 to +29.2‰ (SMOW) and exhibits a marked positive shift in the Upper Krol.

The previous workers[5] have opined that the carbon

isotope variations of Krol–Tal sedimentary carbonates of the Lesser Himalaya represent pristine isotopic signatures as these successions have not been subjected to any metamorphism, deformation and excessive burial. We therefore consider that the $\delta^{13}C$ data reported here represent unaltered signatures.

The isotopic trends presented in Figure 2 show that ^{13}C maxima of +4.9‰ and +6‰ (PDB) relate to the major carbonate successions of the Deoban and Krol, and that the ^{13}C minima of −4‰ and −6.2‰ (PDB) are associated with terrigenous clastic deposits with minor carbonates of the Blaini and Tal formations, respectively. The marked increase in carbonate sedimentation during Deoban and Krol times would imply increased fixation of carbon dioxide in the form of carbonate carbon (C_{carb}). Deoban and Krol carbonate sedimentation represents a time span of Riphean to Vendian[7–17], a time interval much larger than the residence time of carbon (~ 10^5 years)[18] in the exogenic cycle. The increased fixation of carbon dioxide in the form of C_{carb} will therefore mean increased availability of CO_2 in the environment existing during Deoban and Krol times. The Deoban and Krol carbonate formations are mainly microbial in nature and their large-scale deposition indicates a relative enhanced build-up of microbial communities which preferentially fixed ^{12}C in the form of organic carbon (C_{org}), this resulting in ^{13}C enrichment in carbonate carbon. ^{13}C maxima thus relate to overall increase in sedimentary carbon ($C_{carb} + C_{org}$) budget, increased availability of carbon dioxide in the prevailing environment, enhanced rate of photosynthesis and possibly warmer climates. Conversely, ^{13}C minima associated with the Blaini and Tal formations may go along with decrease in the total sedimentary carbon budget (as evident from field observations and marked negative $\delta^{13}C$ signatures), reduced rate of photosynthesis, lower concentration of CO_2 in the prevailing environment and possibly colder climates. The colder climates during Blaini times is envisaged by its possible association with the Varangian glaciation event[4]. There is no evidence of colder climates during Tal times.

The $\delta^{18}O$ records of Late Precambrian–Cambrian carbonates are considered to be artifacts of diagenetic alterations[3] or post-depositional isotope exchange equilibration processes[19], but we suggest that this may not be the only possible reason. The Krol carbonates depict a distinct ^{18}O maxima that associate with carbon isotope maxima (Figure 2). ^{13}C maxima has been interpreted in terms of increased carbon burial and enhanced rate of photosynthesis which has been the main source of oxygen build-up in the atmosphere. Further, the Krol sedimentary succession exhibiting distinct ^{13}C and ^{18}O maxima may be related to the evolutionary transition from unicellular life forms to multicellular metazoans and metaphytes, these must have originated in high oxygenated environment[4,20,21]. Therefore, we associate ^{13}C and ^{18}O maxima with intervals of high environmental oxygen level similar to or higher than the present one. However, the causative reason for link between ^{18}O maxima and higher oxygen levels still remains questionable.

It is concluded that $\delta^{13}C$ and $\delta^{18}O$ variations across Pc–C stages relate to the marked changes in the carbon and oxygen fluxes.

Hypoglycaemic and antihyperglycaemic effects of *Aegle marmelos* leaves in rabbits

V. V. Rao, S. K. Dwivedi, D. Swarup and S. R. Sharma

Division of Medicine, Indian Veterinary Research Institute, Izatnagar 243 122, India

Hypoglycaemic and antihyperglycaemic effects of an aqueous extract of *A. marmelos* leaves were studied in normal and alloxanized-rabbits respectively. In normal rabbits, the highest decrease (35.3%) in blood glucose level was recorded with 1 g equivalent dose after 4 h of administration. The hypoglycaemic effect at 12 h was moderate but no effect was observed at 24 h of drug administration. In diabetic rabbits, the extract produced significant ($P < 0.01$) antihyperglycaemic effect within 3 days when given at the dose equivalent to 1 g powder/kg/day.

AEGLE marmelos Linn. (Rutaceae; Bael) is a widely distributed plant in India and the leaf juice of this plant is used orally by Indian Ayurvedic practitioners for the management of diabetes mellitus[1,2]. However, scanty scientific information is available on the hypoglycaemic activity of *A. marmelos* leaves. We report here the role of an aqueous extract of *A. marmelos* leaves as a hypoglycaemic agent in normal and alloxan diabetic rabbits.

Fresh green leaves of *A. marmelos* procured locally were dried in the shade, powdered and boiled with distilled water. After filtration through Whatman filter paper No. 40, the extract was dried by slow heating and continuous stirring. The yield of the extract was 32%.

Adult albino rabbits of either sex and weighing 1.5–2 kg were used in these experiments. The animals were maintained on standard feeding and managemental condition[3].

Hypoglycaemic effect of the extract was evaluated in 24 fasted albino rabbits divided into four groups of 6. The animals of group-I received 20 ml of distilled water *per os*, while the other three were treated orally with an aqueous extract equivalent to 0.5, 1.0 and 1.5 g powder/kg respectively. Blood glucose was estimated[4] at 0, 4, 12 and 24 h following administration of the test drug and the percentage glycaemia variation was calculated for each group. A comparison was also made between 0, 4, 12 and 24 h values of different groups.

Antihyperglycaemic effect was evaluated in alloxan-diabetic rabbits[5] divided into three groups of 6. Group-I received extract equivalent to 1 g powder/kg/day, group-II was given reference drug (Phenformin @ 125 mg/rabbit) while group-III (untreated control) received 20 ml of distilled water. Treatment schedule was continued for 10 consecutive days. The diabetic blood glucose value (day 0) was compared with post-treatment values on days 3, 5 and 10 in all the groups. Comparison was also made between glucose values of different groups at different time intervals. The data were analysed statistically using analysis of variance and paired '*t*' test[6].

Result of the effect of aqueous extract of *A. marmelos* leaves on blood glucose level of normal rabbits is presented in Table 1. The test drug in all the three doses produced significant ($P < 0.01$) hypoglycaemic effect after 4 h of administration. However, it was more marked in animals receiving aqueous extract equivalent to 1 g powdered leaves (group-III). The hypoglycaemic effect was moderate with all the three doses at 12 h

Table 1. Effect of an aqueous extract of *A. marmelos* leaves on blood glucose level of normal rabbits (mean ± SE)

Treatment	Dose equivalent to g powder/kg	Blood glucose levels (mg/100 ml)			
			Post-treatment (h)		
		0	4	12	24
Distilled water	20 ml	97.1 ± 0.8^{A}	96.0 ± 0.9^{A} (1.1)	93.3 ± 0.7^{A} (3.9)	89.7 ± 0.6^{A} (7.6)
Extract	0.5	95.8 ± 1.0^{A}	74.3 ± 1.2^{B} (22.4)	85.5 ± 1.0^{B} (10.7)	89.8 ± 0.4^{A} (6.2)
Extract	1	96.2 ± 1.3^{A}	62.2 ± 0.8^{C} (35.3)	81.4 ± 0.7^{C} (15.4)	88.0 ± 1.5^{A} (6.2)
Extract	1.5	94.4 ± 1.2^{A}	73.1 ± 1.4^{B} (22.6)	78.8 ± 0.8^{C} (16.5)	86.4 ± 1.6^{A} (8.4)

Table 2. Effect of an aqueous extract of *A. marmelos* leaves and phenformin on blood glucose levels of diabetic rabbits (mean ± SE)

		Blood glucose levels (mg/100 ml)			
		Diabetic level	Post-treatment (days)		
Treatment	Dose	0	3	5	10
Extract	Equivalent to 1 g powder/kg	263.1 ± 4.7^{A}	201.6* ± 5.3^{C} (–23.4)	184.7* ± 5.9^{B} (–29.8)	129.4* ± 3.4^{C} (–50.8)
Phenformin	@ 125 mg per rabbit	278.7 ± 6.0^{A}	239.9* ± 8.2^{B} (–13.9)	186.1* ± 5.5^{B} (–33.2)	114.6* ± 2.1^{B} (–58.9)
Distilled water (untreated control)	20 ml	276.1 ± 4.8^{A}	292.7* ± 4.0^{A} (+ 6.0)	314.2* ± 4.2^{A} (+ 13.8)	333.8* ± 4.0^{A} (+ 20.2)

Figures in parentheses indicate % reduction (–), or increase (+) over diabetic level.
*Significantly different from diabetic level ($P < 0.01$).
Capital letters indicate between group comparison.
Means having different letters are significant ($P < 0.01$) but same letters are non-significant.

and no significant difference in blood glucose level between treated and control group was observed at 24 h.

Table 2 summarizes the effect of an aqueous extract of *A. marmelos* and phenformin on blood glucose level of diabetic rabbits. Both phenformin and aqueous extract of *A. marmelos* were found to have significant ($P < 0.01$) antihyperglycaemic effect after day 3 of treatment. It is interesting to note that on day 3, aqueous extract of *A. marmelos* had comparatively higher antihyperglycaemic effect, while phenoformin was found more effective in reducing blood glucose level on day 10. In untreated diabetic rabbits there was a significant ($P < 0.01$) rise in blood glucose levels from day 3 onward.

These findings indicated that an aqueous extract of *A. marmelos* had a significant hypoglycaemic effect in normal rabbits which lasted for 12 h and the effect was dose-dependent up to 1 g equivalent of powder. However, the response decreased at 1.5 g/kg dose. Such a phenomenon of less hypoglycaemic response at higher doses is not uncommon with indigenous plants and has been observed with *Vinca rosea*[7] and *Cinnamomum tamala*[8]. The extract also produced marked decrease in blood glucose level in diabetic animals. The possible mechanism of the hypoglycaemic effect of *A. marmelos* in normal and diabetic rabbits is not clear. It may be supposed that in normoglycaemic rabbits, the extract exerted hypoglycaemic effect similar to phenformin by stimulating β-cells to release insulin. However, in diabetic rabbits the extract could not have acted by stimulating the β-cells as the alloxan treatment causes permanent destruction of the β-cells. *Ocimum sanctum* leaves[9] and seeds of *Cajanus cajan*[10] have been reported to produce an antidiabetic effect by inhibiting absorption of glucose from the intestine. The possibility of reduced absorption of glucose from the intestine after *A. marmelos* administration cannot be ruled out. A similar explanation has been put forward for antidiabetic activity of *Musa sapientum*[3] and *Caesalpinia bonducella*[5]. Aqueous extract of *A. marmelos* was, therefore, found to have antihyperglycaemic activity in normal as well as alloxanized rabbits, but the precise mechanism whereby this effect is mediated warranted further investigations.

Do dholes (*Cuon alpinus*) live in packs in response to competition with or predation by large cats?

Arun B. Venkataraman

Department of Entomology, University of Agricultural Sciences, Bangalore 560 065, India and
Indian Institute of Science Field Station, Centre for Ecological Sciences, Masinagudi 643 223, India
*Centre for Ecological Sciences, Indian Institute of Science, Bangalore 560 012, India

Interactions between carnivores during the defence of kills may be one reason why certain carnivores live in groups. This is especially true of lions, hyaenas and the African wild dog. The dhole or the Asiatic wild dog, primarily a pack living animal, has been observed to regularly interact with both tigers and leopards. Such interactions have taken place over kills and otherwise. In this report, five such interactions are described. It was found that the pack's behaviour of surrounding bushes and trees on which the cat was confined precluded immediate escape. The presence of sentinels, while the pack was resting, warned the pack of the presence of a big cat and the pack grouped when a big cat appeared. Costs to both individuals within the dhole packs and the cats involved in the encounters were found to be slight. The reasons for such potentially costly encounters could be competition for finite food resources or thwarting predation. Dholes have a significant diet overlap with both leopards and tigers and aggressively encounter with leopards but not with tigers. Differences between diet overlaps may not be the basis behind the differences in aggression. It is more likely that, the small size of leopards and the fact that they predate more often on dholes, cause dhole packs to be more aggressive to leopards than to tigers. The size of carnivore groups may thus pose an advantage during competitive interactions among carnivore species.

AGONISTIC interactions between carnivore species have been observed during the defence of kills. Lions (*Panthera leo*) regularly defend their kills from the spotted hyaena (*Crocuta crocuta*)[1]. One of the adaptive forces moulding the formation of packs in the African wild dog (*Lycaon pictus*) may be the advantage in numbers for the defence of kills from other species such as the spotted hyaena and for appropriation of kills from other carnivores. In the Selous National Park, Tanzania, wild dogs co-operated in the defence of kills from spotted hyaenas which managed to appropriate only 2% of wild dog kills (Creel and Creel, unpublished manuscript). In contrast, in the Serengeti National Park where hyaenas live in larger groups, the duration that wild dogs retained their kills depended on the ratio of individuals of the two species present[2]. Selous wild dogs often appropriated kills from other carnivores. Very pertinent to this report were the observations that leopards were driven up trees on two occasions and on one of these occasions a kill was appropriated (Creel and Creel, unpublished manuscript). Hyaenas and lions were also occasionally driven off kills which were later appropriated (Creel and Creel, unpublished manuscript).

Accounts of interactions between dhole or Asiatic wild dog packs (*Cuon alpinus*) (for a description of dhole biology, see refs. 3 and 4) and other major carnivore species do occur, with most of the accounts concerning those with the tiger (*Panthera tigris*) and the leopard (*Panthera pardus*)[3,5–13]. The outcome of these encounters though more often favouring the dhole packs involved (when tigers or leopards were killed or driven off), did on occasions result in members of dhole packs getting wounded or killed.

Here I report five separate instances of a dhole pack interacting with four leopards and one tiger (Table 1). One encounter involved one of our study packs and four, the other. The two dhole packs involved in the encounters have been monitored since 1988 and have their home ranges within the Dr J. Jayalalitha sanctuary (formerly Mudumalai sanctuary), Nilgiris District, Tamil Nadu, India[4]. Corroborating the above observed encounters are three other encounters (dhole packs interacting with two leopards and one tiger) which have been reported to the author by other observers. Based on this evidence I feel that such encounters are at the least, not infrequent and have a strong basis behind them. This paper therefore describes the above five encounters and attempts to look at two hypotheses as to why such encounters take place. The first hypothesis is that dhole packs aggressively encounter with leopards and prefer not to with tigers, as the former's prey may significantly overlap with that of dholes while the latter's does not. Coupled with overlap in prey are the relative differences in body weights between the two cats in question and a pack of dholes. Leopards weigh 2–3 times less than tigers do and are an easier adversary for dholes to take on[14]. Even if tigers' prey overlap significantly with those of dholes, the greater body weight differences may result in a high cost of interaction causing the interacting dhole pack to avoid tigers. The second hypothesis is that leopards may prey on single dholes and the aggressive encounters occurring within common hunting areas may drive away leopards, at least temporarily, thwarting sneak attacks on single dholes separated from the pack while hunting.

Table 1 summarizes the details of the above encounters. In all cases where dhole packs encountered leopards, a considerable amount of effort was deliberately put into

Table 1. Details of dhole–large cat interactions

Date	Cat	Estimated wt. of cat (kg)	No. of adults	No. of pups ≤ 1 yr	Context	Behaviour of cat	Behaviour of pack	Time spent in interaction (min)	Consequence
21.8.93	Leopard	50	8	6	None	Climbed 4 separate trees	Entire pack surrounded all 4 trees on which cat climbed and initially prevented cat from climbing down	50	Leopard escaped without wounds or wounding any dhole
9.1.94	Leopard	80	5	1 (1 yr 1 month)	Den	Climbed bush	Entire pack surrounded bush on which cat climbed and prevented cat from climbing down	96	Leopard escaped without wounds, inflicted scratches on 2 dholes
23.5.94	Leopard	50	11	6	None	Climbed tree	Entire pack surrounded tree	20	Leopard escaped without wounds or wounding dholes
16.9.94	Tiger	> 200	10	8	None	Initially approached pack and then moved away	Single dhole gave alarm calls after seeing tiger. Single dhole confronted tiger and then moved away. Pack moved away and bunched up.	5	Mutual avoidance resulting in no wounds to tiger or dholes
18.1.95	Leopard	50	8	2	Chital kill	Leopard driven from its kill and then driven up tree	Dholes kept leopard up tree after hunting sambar unsuccessfully and consumed entire carcass	30	Leopard left after dholes finished eating carcass and left

harassing the carnivore. The encounter with the tiger suggests, in contrast to the literature, that dholes may prefer not to engage directly with a larger adversary. An earlier account, reported by an observer to the author, which occurred during the study period, confirmed this speculation. A pack of six animals was enough to engage a leopard for 1 h 35 min with a small cost to pack members. Ten dholes were sufficient to deter a tiger from confronting with the pack. Nine dholes could appropriate a kill from a leopard, after hunting unsuccessfully for at least the last 24 h, thereby providing an alternative source of food.

The first hypothesis tested is that such interactions arise over competition for finite food resources. Out of 12 species the three carnivores feed on[15], we have chosen 5 for subsequent analysis. The hair of 5 species have been identified in the scats of the three carnivores, collected from the study area (Arumugam, unpublished). Because of the lack of density estimates, data from black naped hair (*Lepus nigricollis*) has been deleted from any analysis involving density estimates. Observed values of the 4 prey species for each predator are the occurrences of hair of each prey species among the total scats collected from that predator. In a chi-square test for independence, expected values are obtained by assuming that hair occurs among scat in accordance to the number of scats produced from a kill of each prey species and the densities of the 4 prey species within the home ranges of the 2 study dhole packs[15]. From a 3×4 contingency table (Table 2), with the 4 prey species as rows and the three carnivores as columns, we obtain a chi-square value of 1158 (d.f. = 6, $P < 0.01$). All three carnivores kill far more chital and sambar than expected but less gaur and cattle which gives rise to the highly significant result. A niche overlap index was also calculated[16]. Black-naped hare and another class called 'others'[4] has been included in the analysis. The values obtained are dhole–leopard: 0.922, dhole–tiger: 0.915, leopard–tiger: 0.939. This analysis indicates that there is considerable over lap between the diets of each of the three carnivores and the overlap is similar for all carnivore pairs. Therefore, if prey overlap is the reason behind the dholes aggression towards carnivores, they should be equally aggressive to leopards and tigers.

The other hypothesis tested is that leopards may predate on single dholes and such encounters deter them from doing so, by driving them away, at least temporarily, from common hunting areas. Predation on dholes by leopards, though not observed during the study period (October 1990–March 1995), has been reported in the literature[11]. Dhole hair occurred in 2% of leopard scat (as compared to 0.6% of tiger scat)[15]. Dholes while resting, always have a sentinel and are alerted by alarm

Table 2. Observed and expected numbers of occurrences of hair of 4 prey species found in scat of dhole, leopard and tiger

	Dhole		Leopard		Tiger

calls of other mammals such as the common langur (*Presbytis entellus*), chital (*Axis axis*) and sambar (*Cervus unicolor*) (Venkataraman, unpublished). Furthermore, in the second encounter described, the leopard was in the proximity of a den containing young pups. It is very likely that harassment may deter sneak attacks on single dholes and pups. Dholes often separate during hunting and have elaborate acoustic communication for reassembling[3]. As mentioned earlier, packs have vigilant members who may thus deter attacks on the group.

In the Bandipur National Park, Karnataka, India, leopards and dholes competed for similar-sized prey but competition was reduced by the leopard's ability to climb and cache prey in trees. Moreover dholes killed more fawns and aged chital, while leopards killed chital of all ages. Tigers may coexist with dholes because of several factors such as spatio-temporal use of habitat and sex and size of prey[17]. Leopards and dholes killed prey of the same weight class while tigers killed prey of a higher weight class. Dholes, however, had a preference for male chital, while leopards did not. Tiger predation was biased towards adult males in chital, sambar, wild pig and towards young gaur[15]. Even though a significant diet overlap has been reported in this paper, competition may be reduced by niche partitioning based on age and sex differences of the prey species and spatio-temporal use of the habitat and prey. This may still cause a reduction and consequent difference in the overlap between the diets of dholes, leopards and tigers. However it is more likely that because leopards are smaller in size and predate more frequently on dholes, they are more aggressively dealt with than tigers are. Even though the ultimate reasons for such confrontations cannot be elucidated with certainty, it is quite evident that a pack could successfully accomplish what a single dhole or even a pair may not. Pack members successfully kept leopards on trees and bushes by surrounding them. A pack could obtain food by driving a leopard away from its kill. A single dhole detected a tiger and warned the pack. The pack bunched up invoking ideas of the selfish herd paradigm[18]. The tiger did not directly confront the pack avoiding a major cost to the pack.

Speculations about the evolution of group size in carnivores have hitherto concentrated primarily on the benefits of numbers while hunting[19]. This report brings to light another advantage of numbers in geographical regions where conflicts between major carnivores may be a definite selective force for the evolution of groups.

Estimates of global methane production from rice paddies based on substrate requirement

Sabyasachi Ghosh, M. C. Jain and Suresh K. Sinha

Division of Environmental Sciences and Water Technology Centre, Indian Agricultural Research Institute, New Delhi 110 012, India

Estimates of methane emission from rice paddies are highly variable and hence debatable. Most of the estimates were made without consideration of the substrate requirements. A mole of glucose should normally produce 2 moles of methane yielding 178 mg methane from 1 g of glucose. In our incubation experiment only 10–11% of this potential efficiency was realized. Estimates of biomass of globally produced rice were made from the yield of rice and thus of the potential leaching of the organic substances which gives an upper limit of 13 Tg global methane production from rice paddies.

RICE paddies have been identified as an important source of methane[1]. This was based on some experiments which did not simulate rice-growing conditions of Asia where 92% of the world's rice is grown. The experiments in Europe and US had high organic matter and nitrogen in the soil (200 kg N ha^{-1}) and continuous standing water with an yield of 7000 kg ha^{-1} as against Asian soils with low organic matter and low fertilizer input, which varies from none to 150 kg N ha^{-1} with an yield average of hardly 2000 kg ha^{-1}. In most of the experiments the emphasis was on developing suitable techniques of sampling and gas chromatography. However, the important observations on diurnal variation in methane emission, and the maximum flux of methane coinciding with the maximum biomass of the crop were not utilized for understanding the limits of methane production. The microbial and biochemical basis of methane production has been known[2], according to which a source of carbon is essential for methane production. Here we report the estimates of methane emission from rice paddies on the basis of requirement of carbon source.

Rice-paddy soils are the source of methane, for which there ought to be a source of carbon. This could be either organic carbon or constant supply of carbon source (carbohydrate or organic acids) from the crop itself[3]. Since soil organic carbon is apparently not a major source of methane because about no methane is produced from soils without a rice crop, hence, it was assumed that a carbohydrate such as glucose would simulate rice-paddy soil for methane production.

Soil samples were taken at random from a depth of 0–15 cm from a plot of 500 m^2 after the rice harvest. The samples were air-dried and sieved through 2 mm mesh screen. The soil samples were incubated at 30± 1°C and 35± 1°C temperature in conical flasks of 1 l capacity each. This range of temperature was chosen because at this temperature rice cultivation in India takes place and methanogenic activity is maximum. Provisions were made in the flask for measurements of pH and Eh, collection of gas samples for methane estimation and collection of liquid samples for estimation of acetate content.

Two hundred and fifty grams of air-dried soil was taken in each flask and distilled water was added to cover the soil with a 5 cm deep layer of water. Nitrogen gas (99.998%) was flushed every 3 days for 5 min to ensure complete anaerobic conditions. Two treatments, viz. control (no glucose) and 1 g glucose, were given to the soil (250 g) in different incubation flasks in three replicates.

Gas samples were collected using 1 ml gas-tight syringe through a three-way valve at a regular interval of 24 h for 30 days. Supernatant water samples were also drawn from the side port of the flask to estimate acetate content. Volume of samples was replenished by equal amount of water.

Gas samples were analysed for methane on a Packard Gas Chromatograph (Model 438) using flame ionization detector (FID)[4]. Stainless steel column packed with molecular sieve 5 Å 60–80 mesh at a temperature of 80°C was used for methane analysis. The injector and detector were kept at 100°C. Nitrogen at a rate of 15 ml min^{-1} and H_2 at a rate of 25 ml min^{-1} were passed through as carrier and fuel gases respectively. The equipment was calibrated and frequently checked against the standard gas samples.

Five ml sample of supernatant aqueous phase above the soil was obtained using a syringe through a side port and was passed through Whatman No. 1 filter paper. The acetate concentration was measured using an Ion Chromatograph (Dionex, Dionex Corporation, USA) fitted with a suppressed conductivity detector and integrator. The column used was 4S 4A-5C. The eluent was a mixture of 1.7 mM sodium bicarbonate and 1.8 mM sodium carbonate in the ratio of 1 : 1 with a flow rate 2 ml min^{-1}. The pump pressure was 1160 psi. Samples were injected through a loop of 25 µl automatically by a pneumatic pressure-operated injector and the excess volume was flushed out. The anions were separated in the column and detected by the conductivity detector and the chromatograms were recorded by the integrator. The acetate concentration in the samples was determined with reference to a standard solution of 30 ppm acetate prepared from ammonium acetate (AR grade).

The pH was measured using the combined electrode in the soil solution through the side port of the flask using digital pH meter, Century-model CP 901. Eh (redox potential) was recorded using the same pH cum mV meter. A platinum micro electrode prepared in the

laboratory was installed permanently in the flask and a calomel electrode through side port served as a reference electrode.

Methane production from control (absence of glucose) at 30°C showed a steep rise from day 7 onwards and reached a maximum value of 0.07 $\mu g\ g^{-1}\ day^{-1}$ by day 18. The production then declined to 0.01 $\mu g\ g^{-1}\ day^{-1}$. The pH during the experimental period varied between 7.1 and 7.9. However, Eh reached – 157 mV by day 13 and then remained between – 183 and – 234 mV from day 17 onward (Figure 1). The correlation coefficient between methane emission and Eh and pH independently was – 0.90 and 0.16 respectively (Table 1).

The incubation of the soil with 1 g glucose gave an emission of 8.88 $\mu g\ g^{-1}\ day^{-1}$ on day 15, being 130 times higher than the control (Figure 1). The Eh also declined sharply to – 480 mV by day 10 and reached – 498 mV by day 25. Initially, the pH was reduced to 6.2 but with the decline in methane production it increased and reached a value of 7.9. The correlation coefficient between emission and Eh was – 0.82, and between methane emission and pH it was – 0.14. Table 1 gives the correlation coefficient between methane emission with Eh and pH. At 35°C, the maximum production of methane (9.03 $\mu g\ g^{-1}\ day^{-1}$) was observed on day 10. The Eh of the system declined below –200 mV by day 12 and reached –410 mV on day 14. The production of methane declined to 0.154 $\mu g\ g^{-1}\ day^{-1}$ by day 30.

Acetate accumulation started by day 5 and day 6 when the Eh was still above –100 mV. In the treatments of 1 g glucose at 30 and 35°C acetate accumulation preceded methane emission. Figure 2 shows this relationship at 35°C.

Methane production from rice paddies has been estimated considering microbiological processes and also the potential requirements of substrate for methane emission[3]. Since plants do release organic substances, such as, sugars and organic acids, these substances would serve as substrates for methane production and other microbial activities such as growth, multiplication and production of metabolites. Assuming that eventually glucose is the substrate, then 32 g methane would be produced from 180 g glucose if there was no reduction of CO_2 to methane or 178 mg methane would be produced for 1 g of glucose. In our experiment the maximum amount of methane production was 17.49 mg and 19.16 mg from 1 g glucose at 30 and 35°C respectively. This means that the substrate utilization efficiency was only 10% and 11% at 30 and 30°C respectively.

The cause of such low efficiency of the conversion of glucose to methane may be due to the following reasons: a) A part of the glucose may be converted to carbon dioxide or got bound in clay organic matter complexes, thus reducing efficiency; b) Inhibitory nature of some of the end product in the process of methane formation may reduce efficiency; c) Methane oxidation in the upper layers of the soil by methanotrophic bacteria may reduce efficiency.

These data can now be used for assessing the carbo-

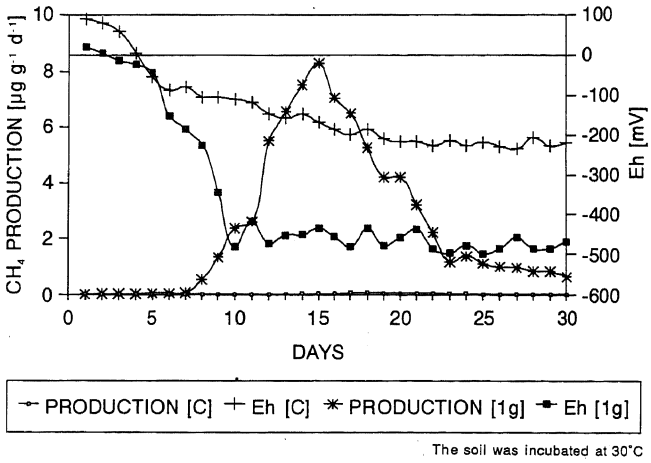

Figure 1. Time-course of redox and methane production with or without glucose amendment.

hydrate requirements for methane production. According to the IPCC (1992), the annual average production of methane from rice paddies is 110 Tg. If the efficiency, as experimentally observed, is taken into consideration, it would require 1100 million tonnes (10% efficiency) or 1000 million tonnes (11% efficiency) of glucose or glucose equivalent for producing 110 million tonnes of methane. Assuming the harvest index of 40%, with an annual rice paddy production of 527 million tonnes, the maximum biomass would be 1300 million tonnes. All estimates made so far suggest that plants can release organic substance up to 10% of their weight through roots[5]. Thus, a maximum amount of 130 million tonnes may be available as substrate for methane production. From this amout only 11 to 13 million tonnes of methane can be produced. Thus an upper limit of 13 Tg methane production from rice paddies can be expected. Any assessment ignoring biological aspects of the mechanism of methane production is an artifact of methodology.

Bacillus thuringiensis, a biocontrol agent for major tea pests

N. Unnamalai and Vaithilingam Sekar

School of Biotechnology, Madurai Kamaraj University, Madurai 625 021, India

A preliminary screening was carried out to determine the efficacy of crystal proteins of nine strains of *Bacillus thuringiensis* to control two lepidopteran pests of tea plants. Among these strains *B. thuringiensis* var. *kurstaki* HD1 and HD73 were highly toxic, *B. thuringiensis* var. *thuringiensis* HD2 was moderately toxic, *B. thuringiensis* var. *aizawai* HD133 showed low toxicity, while the other strains showed no toxicity towards these pests. The LC_{50} values of the three toxic strains and that of the purified crystal protein of the highly toxic strain HD1 were determined by laboratory bioassays.

TEA is an important plantation crop of India and is affected by many pests. The two most economically important lepidopteran insect pests of tea are the leaf-feeding caterpillars, *Caloptilia theivora* (leaf roller) and *Cydia leucostoma* (flushworm), belonging to the family Gracillariidae and Olethreutidae respectively. They cause considerable damage to young leaves of the tea plant by destroying the apical bud and tender leaves, thereby arresting the shoot growth.

The choice of conventional insecticides to be used on this crop is limited because of concerns related to consumer protection and environmental safety. Hence the search for effective biopesticides for the management of tea pests becomes appropriate. We undertook a study on the feasibility of the use of *Bacillus thuringiensis*, a well-known entomopathogen, as a biopesticide in tea plantations.

We carried out a preliminary screening for the efficacy of the crystal proteins of various *B. thuringiensis* strains belonging to class I which are known to be toxic to lepidopterous insects (Table 1). These strains were cultured on nutrient agar plates (peptone, 5 g; NaCl, 5 g; yeast extract, 1.5 g; beef extract, 1.5 g; distilled water, 1000 ml; pH 7.4) for four days at 30°C. One plate was used for each strain. The resultant spore–crystal mixtures were scraped off the plates, washed once in 0.5 M NaCl, followed by three washings in sterile water and resuspended in 1 ml of sterile water containing a protease inhibitor phenylmethylsulphonyl fluoride, at a concentration of 1 mM. These crude preparations were stored at –20°C until further use.

The pure crystal protein preparation was made from the spore–crystal mixture of HD1 (ref. 1). The purity of the crystals was 95% as determined by light microscopy. The level of purity of crystals was also confirmed by SDS–PAGE analysis[2]. Protein concentration of the spore–crystal mixtures of all nine strains and the purified crystal fraction of the strain HD1 were estimated by the dye-binding method[3] after solubilizing the crystal inclusions at 37°C in 10 mM NaOH (pH 10.5) containing 25 mM dithiothretol.

Prior to setting up bioassays, the surface area of the leaves was measured. Preliminary bioassays were conducted using crude spore–crystal samples obtained from the nine strains of *B. thuringiensis* towards larvae of flushworm and leaf rollers. Assays were done at 28°C

Table 1. Various strains of *B. thuringiensis* used in the study

Strain	Serotype
B. thuringiensis var. *kurstaki* strain HD1	3a 3b
B. thuringiensis var. *kurstaki* strain HD73	3a 3b
B. thuringiensis var. *thuringiensis* strain HD2	1
B. thuringiensis var. *aizawai* strain HD133	7
B. thuringiensis var. *indiana* strain HD521	15
B. thuringiensis var. *dakota* strain HD551	16
B. thuringiensis var. *pakistani* strain HD395	13
B. thuringiensis var. *morrisoni* strain HD12	8a 8b
B. thuringiensis var. *galleriae* strain HD207	13

Table 2. Bioassays using the spore–crystal mixtures of various *B. thuringiensis* strains[a]

Strain	Percentage mortality after 72 h[b]	
	Flushworm	Leafroller
HD1	70	60
HD73	60	65
HD2	45	45
HD133	30	25
HD521	0	0
HD511	0	0
HD207	0	0
HD12	0	0
HD395	0	0
Control*	0	0

*Water-coated leaves were used as control.
[a]Leaves coated with 200 ng cm^{-2} of crude crystal protein were used.
[b]Average of three replicates.

Table 3. Toxicity of selected crude/purified crystal proteins against flushworm and leafroller

Strain	Flushworm*		Leafroller*	
	LC_{50}** (ng cm^{-2})	95% fiducial limits	LC_{50}** (ng cm^{-2})	95% fiducial limits
HD1	185.36	151.39–226.95	174.97	143.84–212.82
HD73	208.95	171.70–254.28	184.05	150.31–225.35
HD2	221.79	184.39–266.78	296.67	178.60–492.80
Purified HD1	40.97	37.02–45.35	33.93	30.07–38.28

*Larval mortalities scored after 72 h.
**LC_{50} values were calculated from three independent bioassay tests.

by coating fresh individual tea leaves with 200 ng cm^{-2} of protein from crude spore–crystal preparation and placing the 2nd instar larvae over it. In all bioassays, a total of 20 larvae/treatment (5 larvae/leaf) were used. The percentage mortality was scored after 72 h. A control was maintained by coating sterile distilled water on the leaves. All bioassays were repeated three times.

LC_{50} values of crude spore–crystal samples of the three toxic strains were estimated by conducting larval bioassays. Different concentrations of crude samples (100, 150, 200, 250, 300 ng cm^{-2}) and the pure crystal protein of the most toxic strain (20, 30, 50 and 75 ng cm^{-2}) were used in the bioassays. The data were subjected to probit analysis[4].

The results of preliminary bioassays showed that *B. t.* var. *kurstaki* HD1, HD73 and *B. t.* var. *thuringiensis* HD2 were toxic to the pests. *B. t.* var. *aizawai* showed some toxicity, while the other strains showed no toxicity towards these pests (Table 2).

Among these three strains, HD1 and HD73 were most toxic to both flushworms and leafrollers. The LC_{50} value of HD1 towards flushworms was 185.36 ng cm^{-2} with a 95% fiducial limit (FL) of 151.39–226.95 and that of HD73 was 208.95 ng cm^{-2} (FL = 171.70–254.28). The LC_{50} value of HD1 towards the leaf rollers was 174.97 ng cm^{-2} (FL = 143.84–212.82) and that of HD73 was 184.05 ng cm^{-2} (FL = 150.31–225.35) (Table 3). The LC_{50} value of the purified crystal protein of HD1 was 40.97 ng cm^{-2} and 33.93 ng cm^{-2} respectively for flushworms and leafrollers (Table 3). The low LC_{50} values observed for the purified crystal proteins when compared to the crude preparations may be due to the presence of significant amounts of the spore proteins in the crude samples.

Attempts to control pests of tea plant using *B. thuringiensis* were made by Kariya[5] in 1977. Recently, CryIA(a) protein of Fu-2-7 strain was reported to be about half as toxic against smaller tea tortrix as the strain HD1. It is known that *B. thuringiensis* var. *kurstaki* strain HD1 produces several lepidopteran toxic proteins such as CryIA(a), CryIA(b), CryIA(c), CryIIA and CryIIB while, HD73 produces only CryIA(c) protein[7]. Since the LC_{50} values for the strain HD73 (containing CryIA(c) protein only) and HD1 (containing several Cry proteins) were quite similar, it is likely that CryIA(c) may be more toxic. Other CryI proteins such as CryIA(a), CryIA(b) and CryIB produced by the strains HD1 and HD2 may also exhibit some toxicity. Studies to establish the relative efficacy of individual Cry proteins to control leafrollers and flushworms are underway.

Morphology of zircons in massive and incipient charnockites of southern Kerala: Their bearing on the origin

G. R. Ravindra Kumar and Narayanaswamy
Centre for Earth Science Studies, Akkulam, Trivandrum 695 031, India

Morphological characteristics of zircons in massive and incipient charnockites show contrasting features between the two types. Significantly greater length/breadth ratio in massive charnockite suggests crystallization in igneous environment, whereas zircons of incipient charnockites point to extended transport, eventual rounding and deposition in sedimentary environment. Further, morphological data agree with the petrological and geochemical observation that the incipient charnockites are probably the highgrade (granulite facies) reaction products of metasediments (argillaceous and arenaceous) whereas massive charnockites developed from igneous protoliths.

ZIRCON is an accessory mineral of great interest in many rocks. The relative abundance, colour, elongation ratio, degree of rounding of zircons can give positive expression as to the nature of origin of the host rock. In the past, several attempts have been made to resolve some controversial petrogenetic problems of distinguishing igneous rock types, origin of granite, metasomatized rocks, different igneous intrusions in an igneous complex, ortho/para nature of gneisses[1–5] using the statistical parameters of zircons. Zircon study has been found especially significant in the study of granite.

We have attempted here the morphological study of zircons to address the mode of origin of two types of incipient and massive charnockites. The incipient charnockite is seen as foliation-blurring discordant coarse-grained patches and the massive charnockite occurs as, occasionally banded, large units in southern Kerala. Our interpretation of statistical data is based on the knowledge of field relationships and the observation of several workers[6–8] that zircons retain a large extent of their premetamorphic characteristics through higher grade of metamorphism and can survive crustal melting events and remain unrecrystallized even under granulite facies conditions.

Southern Kerala is essentially a granulite-facies terrain. A major shear zone called the Achenkovil shear zone separates the high-grade terrain into a northern region dominated by garnet- and graphite-free massive charnockites, from the southern region dominated by metasedimentaries. The metasedimentary unit, also known as Kerala khondalite belt (KKB) consists of graphitic garnet–sillimanite–biotite–cordierite gneiss with less abundant calc-silicate and quartzites. Widespread occurrences of incipient charnockites are noted within the supracrustal assemblages of the KKB. Rb–Sr and U–Pb dating of khondalite group suggest the age of khondalite to be 1900–2200 my (ref. 9–11). It has been suggested by Chacko *et al.*[10] that the khondalite belt may be representing Proterozoic fault-bounded basin that received much of its arkosic sediments from granitic high lands and deposited over the pre-metamorphic equivalent of massif charnockites (tonalitic orthogneiss). The incipient charnockite-forming event appears to be a late Proterozoic event (540 my (ref. 9)). Previous morphological study of zircons of khondalites and massive charnockites suggested respectively sedimentary and magmatic origin for the rock types[12]. In this study we have selected an incipient charnockite from Nedumangad (Lat 8°42″; Long 77°02″) and a massive charnockite 2 km east of Vadasserikara (Lat 9°21″; Long 76°50″) to study the morphological characters of zircons and to verify the data against the prevailing views that (a) charnockites in southern Kerala are magmatic[13] and (b) the massive charnockites are igneous and incipient charnockites formed from metasediments[9,10,14].

The massive charnockite was collected from the northern margin of the Achenkovil shear zone and at the northern terminus of the KKB. The rock is medium grained with greenish to greyish black colour. It occurs as a large massive body with no diagnostic structural element in quarry exposures but the weathered portions reveal gneissic layering. The rock is made up of a typical granulite facies assemblage of quartz + alkali feldspar + plagioclase (An_{40}) + hypersthene + hornblende + magnetite and zircons, set in a hypidiomorphic texture. Graphite and garnet are absent.

The incipient charnockite was collected from a fresh active incipient charnockite quarry near Nedumangad. The charnockite is interlayered with graphitic garnet biotite gneiss. Sillimanite-bearing pelitic gneiss (khondalite) occurs few metres away but in the same interlayered sequence. Distinct planar fabric defined by garnet and biotite is present in the charnockite. No cross cutting relation between gneiss and charnockite, which could be assigned to an igneous process was observed. The field relationships between gneiss and charnockite are similar to those seen in incipient charnockite localities of south Kerala[9,14]. The rock is coarser grained with a mineralogy of quartz + K-feldspar + plagioclase (An_{35}), garnet + biotite + hypersthene + graphite + ilmenite and zircon set in a homogeneous granoblastic texture.

Zircon was separated following the method of Murthy *et al.*[15]. The work involved crushing of samples to –60 mesh, washing to eliminate fine powder fraction and heavy mineral separation at 1.4 amperage with forward slope of 15° and side tilt of 20° using isodynamic separator. The nonmagnetic concentrate containing zircon was treated in methylene iodide and clericii solution.

Table 1. Morphological data of zircons

Charnockite	Colour	Euhedral/ terminally rounded	Rounded	Over growths	Metamict	Inclusions
MC 278: Massive (ortho)	Colourless	97.5	2.5	8	1.5	53.5
IC 279: Incipient (para)	Colourless to light brown	75	25	3.5	2	34.5

Table 2. Statistical data on zircons

Charnockite	$\bar{X}$	$\bar{Y}$	N	SX	SY	r	a	θ	σa	Dd
Massive	0.3027	0.1162	200	0.1185	0.0376	0.5345	0.3173	17°36″	0.0189	13.69
Incipient	0.2009	0.1137	200	0.0891	0.0429	0.0457	0.4815	25°46″	0.0340	35.51

Final purification was made by hand picking under stereobinocular microscope. Two hundred unbroken zircons were used for statistical morphological studies (Tables 1 and 2). Statistical computations are based on the measurement of mean length ($\bar{X}$), mean breadth ($\bar{Y}$), standard deviation of length (SX) and breadth (SY), standard error of slope (σa), coefficient of correlation (r) and relative dispersion (Dd).

Zircons generally occur as tiny crystals in very minor quantities in both the rocks. They are translucent and colourless, which are characteristic of granulite-facies varieties[16,17]. Minor occurrence of hyacinth coloured varieties is noticed. Four types of zircons are noted in both the rock types, viz. euhedral, terminally rounded, subrounded and rounded. Globular and rod-like inclusions are fairly common in zircons but overgrowths and zoning are uncommon.

The statistical parameters of zircons are given in Table 2. In massive charnockite, zircons vary in length from 0.11 to 0.8 mm and breadth from 0.05 to 0.29 mm. Up to 73% is terminally rounded and does not show any angle between length and C-axis. 25% of zircon population is made up of euhedral crystals (Figure 1 *a*). Overgrowths are negligible. The size–frequency study, following the method of Larsen and Poldervaart[6] suggests length maxima, depicting polymodal prominent peak at 0.225 mm and breadth maxima depicting a monomodal, prominent peak at 0.1 mm (Figure 2 *a, b*). The elongation curve is sharp monomodal with a maxima at 2.5 mm (Figure 2 *c*).

In incipient charnockite a high percentage of rounded zircons (~ 25%) was noted (Figure 1 *b*). Euhedral and terminally rounded zircons make about 18% and 57% respectively. Overgrowths are seen in about 4% of the zircons. Variable angle between length and C-axis is noted in the rounded zircons.

The data of length (0.08–0.54 mm) and breadth (0.05–

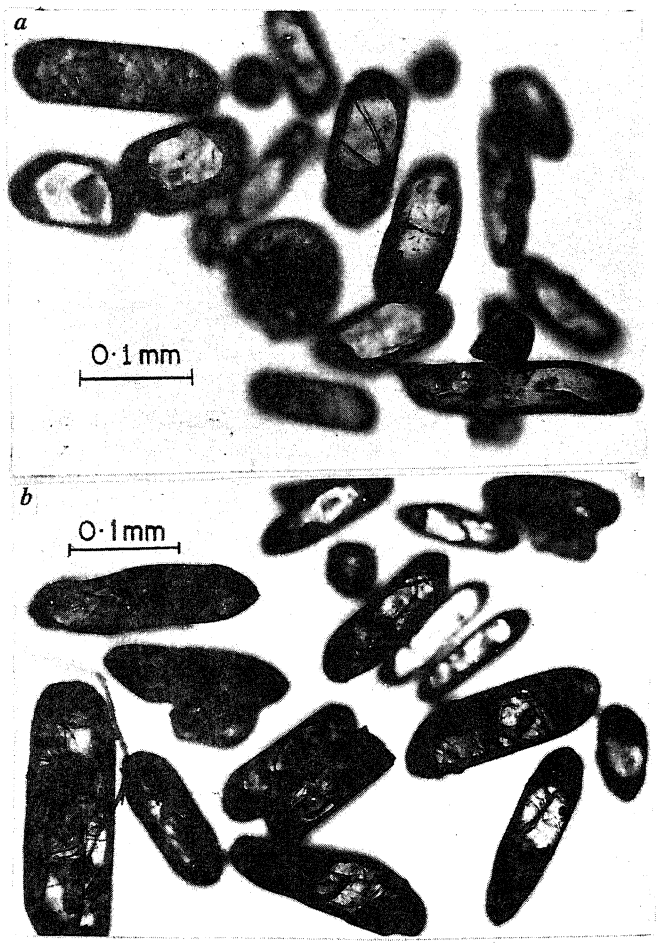

Figure 1. *a*, Zircon crystals from massive charnockite. Note the corroded and terminally rounded margins and euhedral shape. *b*, Zircon crystals in incipient charnockite. Observe that a majority of zircons show rounded and a few show euhedral shapes.

0.32 mm) analysed according to Larsen and Poldervaart[6] suggest polymodal length maxima at 0.175 mm, and sharp monomodal prominent peak with a breadth maxima at 0.75 mm (see Figure 2 *a, b*). Elongation curve is sigmoidal (Figure 2 *c*).

A statistical method of treating zircon by reduced major axes (RMA) technique was developed and tested by Larsen and Poldervaart[6]. It is considered to depict the growth trend line of zircon. This trend line also provides a means of evaluating any differences between the rock types. This method follows a simple principle that zircons crystallized from the same magma will have similar physical properties and follow a linear distribution in length–breadth scatter diagram. To test the differences between the incipient and massive charnockites, the reduced major axes of these rocks have been plotted (Figure 3) following the method of Larsen and Poldervaart[6]. The visual comparison of RMA shows significant variation with different slopes for incipient and massive charnockites. The variation in the slope decreasing with increase in elongation of zircons shows that these rock

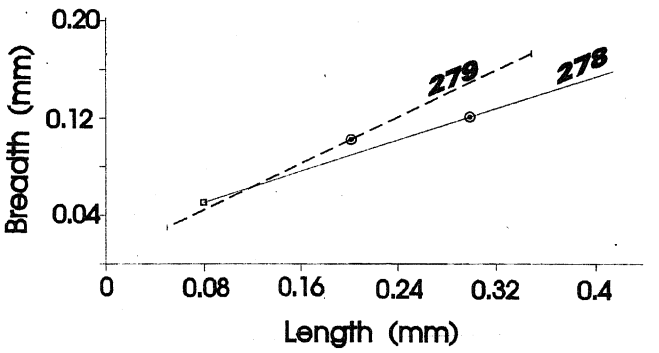

Figure 3. Reduced major axes of length (mm) and breadth (mm) measurement of massive (unbroken line) and incipient charnockite (broken line).

types belong to diverse source region and have entirely different nature of origin. The noncomparable RMA slope position of euhedral and rounded zircons of incipient charnockite suggests dominant detrital nature and the rounding of zircons as due to sedimentary processes. However, similar tests on the zircons of massive charnockite suggest a comparable RMA slope, suggesting the rounding of zircons of these charnockites to be due to corrosion[18].

From the present study it is clear that the characteristics of zircon in massive charnockite are in contrast to those in the incipient charnockites. Higher percentage of euhedral zircons is seen in massive charnockite whereas the zircons of the incipient charnockite are detrital in character and have relatively greater percentage of rounded zircons. This suggests that the precursor rocks of incipient and massive charnockites may have formed in different environments. Terminally rounded nature of zircons ascribed to corrosion, and relatively higher euhedral zircons in massive charnockites favour igneous origin. Moderately well rounded and a few terminally rounded zircons in incipient charnockites suggest diverse source and some of them to be reworked. Further, the zircons from massive charnockite have significantly greater length/breadth ratios than the incipient charnockite zircon varieties. The low length/breadth ratios of zircons of incipient charnockite are consistent with a sedimentary protolith for this rock type. Although less, significant presence of euhedral zircons and terminally rounded zircons in incipient charnockite supports the contention that the immediately adjacent high land areas where massive charnockite are abundant[10] provided the detritus to the depositional basin, whereas the rounded zircons suffered a long distance transport.

INDIAN INSTITUTE OF SCIENCE
BANGALORE 560 012

Post Doctoral Research Associateships in Life Sciences and Biotechnology
(A DBT-sponsord programme)

Applications are invited from candidates with Ph D in Biological, Chemical or Physical Sciences, or MD, for the award of temporary Research Associateship (maximum duration – 2 years) to carry out research in frontier areas of Biology in the Division of Biological Sciences at IISc under the DBT-sponsored postdoctoral programme. Candidates *who have submitted their theses* (awaiting award of degree) are also elibigle to apply, but they may be appointed as Research Associates (Provisional) till they obtain the degree. Minimum consolidated emoluments for Research Associates will be around Rs 4,000 p.m. This is an ongoing programme and the PDFs award will be operative from 1 April or 1 October of every year.

Candidates should apply on plain paper giving: (1) Biodata; (2) Summary of Ph D work including list of publications (reprints if any); (3) Two reference letters, from supervisor and persons familiar with their scientific work; and (4) An undertaking that they will continue with the training programme for its duration.

After initial screening, candidates will be called for an interview at IISc., Bangalore in the first/second week of March/September 1996. The PDF programme will start from 1st April/October 1996. Send applications to Prof. K. P. Gopinathan, Chairman, Department of Microbiology and Cell Biology, Indian Institute of Science, Bangalore 560 012 to reach him before **31 January 1996/15 August 1996.**

Annual Review of Immunology 1995. William E Paul, ed. Annual Reviews Inc., 4139, El Camino Way, Palo Alto, California, 94303-0139, USA. Price: USA $ 48, elsewhere $ 53. Vol. 13. 729 pp.

The first 'personal essay' in the first volume of the *Annual Review of Immunology* in 1983 was written by Elvin Kabat, who watched over the progress of immune phenomena from physiology to biochemistry. The first actual review in that volume was written by Gustav Nossal, who writes, a dozen years later, the personal essay for this volume, and documents the progress of immune phenomena from the cellular to the molecular level. The difference between those two transitions is central to what has happened in immunology over the past decade, as a shift from the organism to its cells, and from biochemical to molecular events.

However, before examining this volume further—what are the *Annual Reviews* supposed to do, anyway? According to the editors, they keep those not directly working in the area 'up-to-date'. This is meaningful only if the 'updating' involves concepts, since few who do not work in an area are interested in its experimental facts. But, since the existence of the *Annual Review of Immunology* was justified in 1983 for its editors [who are still at its helm] by the sheer bulk of work in immunology, it is more likely that the reviews would be collections of technical facts rather than ground-breaking conceptual arguments, which is what happens, albeit with rare honourable exceptions. The reviews are compendia more than commentaries, and they seem to be content to be that, especially given, one supposes, the number of other 'review' periodicals in immunology that are pithier, shorter and 'laity-friendly'.

One result of this is that 'comprehensiveness' has become a special virtue for these volumes. This has led to two things. One, they simply tend to document the changing faces of experimental systems or 'phenomena' in immunology. This is aggravated by the fact that immunology is still a science that is frequently shifting its basic paradigms as the result of major experimental discoveries of 'phenomena', so that 'theories' seem more ephemeral to immunologists than they do, perhaps, to professionals in other, more 'established' sciences, although the allure of immunology also lies in that uncertainty. Two, this virtue of comprehensiveness has led the editors of the *Annual Reviews of Immunology* to declare [in the first volume itself] that appropriate scientists would be asked to write reviews on a broadly representative range of topics in immunology. This has meant that reviewed areas have not necessarily seen any major recent changes fundamental enough for the reviews to be anything but compendia of technical facts. All this makes the *Annual Reviews of Immunology*, and this volume no less than previous ones, boring to the casual reader from sister disciplines, and of utility mainly to workers looking for an easy survey of their field, with the pitfall that, since these are still reviews written by individuals, the 'comprehensiveness' may after all be idiosyncratic and less than all-embracing.

In judging the success of such a volume, therefore, all the poor reviewer can do for the lay reader is to survey what the volume does review, and, maybe, what possible lacunae there may be. But the latter is made difficult by the fact that the process of selecting topics and reviewers begins about two years before the publication of an Annual Reviews volume. Results of recent days that may, one thinks, merit a mention, such as the DM gene products, will therefore find space only in later years. This means that the wish of the editors of *Current Science*, that the book reviewer should essay a short review of the state of the art, would create an untenable situation where the book reviewer discusses issues that the volume itself does not mention.

After all this, what DOES this volume actually contain? Well, one can perhaps divide work that passes under 'immunology' into four broad areas: one, issues of interest uniquely to immunologists and for the moment to few other people, which usually means the generation and consequences of the clonally diverse recognition mechanisms that are the mainstay of the vertebrate immune system and are what classical immunologists mean by 'adaptive' immunity; two, issues that deal with a broader notion of 'defense' in eukaryotic organisms or what classical immunologists call 'innate' immunity; three, analyses that simply use the immune system to answer questions of general interest to all biologists such as in developmental regulation and signal transduction; and four, what everybody is interested in, how immunology explains, treats, prevents, or cures diseases. The present volume has a reasonable selection of subjects representing this entire range, in the proper tradition of 'political correctness'. In fact, it is instructive to look at how much of the present volume is dedicated to diseases—almost a half of it as opposed to barely a fifth in the first volume in 1983. This reflects both the fact that immunology has matured enough to be able to look at diseases without looking foolish, as well as the changing political climate for research funding everywhere, which has, in this era of post-modern conservatism, come to insist on immediate delivery of usable value for every penny spent on research.

Thus, adaptive immunity is represented by discussions about selection of the T cell repertoire, the effects of deletion of the MHC class II molecules in engineered mice, the basis of immune reactivity to so-called type 2 T-independent antigens, interleukin-12, and the relevance of CD19 in generating B cell responses. Innate immunity is represented by peptide antibiotics of mammalian origin, by the transcriptional regulation of complement genes, by the interactions of bacterial lipopolysaccharide with the immune system, and more dubiously, by a discussion of the effects of the neuro-endocrine axes on 'autoimmunity'. Issues of general interest in biochemistry and molecular biology discussed include the role of the *bcl-2* gene product in cell survival and death, signalling through cytokine receptors in haemopoietic cells, and potassium and calcium channels in lymphocytes. Reviews that purport to deal with diseases in the context of the immune system cover a very wide range, from situations where the disease is simply a tool for fundamental questions in adaptive immunity such as the essay on retroviral superantigens, through 'softer' issues such as the immune responses to *Leishmania major*, hepatitis B virus and HIV, via a discussion of the genetics of a so-called autoimmune disease animal model in the non-obese diabetic mouse and an attempt to link another disease 'model', reactive arthritis, to a more baffling disease, rheumatoid arthritis, finally to pieces that deal with therapeutic possibilities. These last possibilities reviewed are mostly conceptual right now, and even there many

of them are vague. They range from cytokine adjuvants for cancer immunotherapy to T cell therapy for human viral diseases and the possibilities in xeno-transplantation of organs, and they could be said to end in a notable review of the politics and mechanics of immunodiagnostic tests, in the example of HIV. This is an eclectic collection by any standards, and as would be expected, the quality varies, although few fall below the minimum required for coherence and 'comprehensiveness'. There is, in fact, a reassuring air of 'solidity' about the latter virtue.

There is, however, a sense of rote about many reviews despite being well-written, because they do not seem to stem naturally from exciting new breakthroughs in their area, but rather come as though an *a priori* decision had been made to include them for extraneous reasons. The sterling exception to that, and arguably the best review in the volume, is the review by Bevan and his colleagues on the selection of the T cell repertoire. It provides a terse and succinct background, sets up the theoretical paradox—that T cells need to recognize something during their development in order to be identified as useful and allowed to survive, but if they do recognize anything in the body at this time they are killed off in order to avoid the dangers of autoreactivity. Having stated the dimensions of the problem, the review then looks at the periphery of the problem, so to say, and examines the current status of ideas and data on, for example, the role of co-receptors in such selection and how these co-receptors are regulated during selection, before plunging into the genesis and testing of the various possible hypotheses that can explain the interactions between T cell receptors and their ligands that has made this so fermenting a field in recent years. The demonstration that peptides have a significant role to play in positive selection rather than only in negative selection of T cells, of landmark value enough by itself, is thus set in context and taken further to bold predictions of what may be happening *in vivo*—a peroration that fits well at the end of a rattling good read. Would that more reviews in this commodious compendium were as riveting.

Annual Reviews of Medicine 1995. Cecil H. Coggins ed. Annual Reviews Inc, 4139, El Camino Way, Palo Alto, California 94303-0139, USA. Vol. 46. Price: USA $ 47, Elsewhere $ 52. 549 pp.

Medical literature has become a big jungle these days, what with more than 30,000 biomedical journals pouring in data at a phenomenal pace. A novice in the field will find it difficult, if not impossible, to get at the rose wood and the teak wood in the jungle, instead he may get lost in the midst of the dead wood. Books like the medical annual will go a long way in helping people to know the useful research data and the milestone developments in their respective fields. This kind of book also could give the distilled wisdom in the field. 'Where,' said T. S. Elliot, 'is the wisdom we seem to have lost in knowledge?' and 'where,' he asked, 'is the knowledge we seem to have lost in information?' To convert the whole lot of information from the ordinary journals one needs to have a system whereby the juniors could get at the truth.

The editors of the medical annual have a very difficult task to pick and choose only a small fraction of the new knowledge generated during the year under review. The chapters in this book will, perforce, have to be patchy and choosy. However, this edition has been more than fair to the subjects under review. They have also selected the right people to do the reviews. People like Norman Kaplan, Erik Mogenson and Mark Pfeffer are all giants in their own fields, to mention only a few whose work I have direct experience of.

Molecular biology, new face of tuberculosis, brain imaging in schizophrenia, newer viruses, ventricular remodelling and organ transplantations are all the hot topics of the day and have all been judiciously reviewed. The index is a pleasure for the reader.

As in the previous issues of the medical annual which I have been following ever since 1964, the present one has kept up its high standards of the contents and the contributors. I had the pleasure of reviewing this good book two years ago for the *British Postgraduate Medical Journal* where I had expressed similar sentiments.

The book has been produced well, the print and the paper are also good. Overall this book should get very high marks and I have no hesitation to recommend it strongly. This must be compulsory reading for all the postgraduates and others in practice. I would have been happier if they had included a review of the newer problems in the field of tropical diseases, as some of them like malaria, have come back with a vengeance, and do not follow the old time pattern at all; as also the dangerous scenario of nosocomial infections.

The research into malaria and its molecular biology is more than just of practical importance. It has more to it than what meets the eye. An important current topic is the localization of genes implicated in the susceptibility to common chronic diseases. This has been greatly facilitated by the use of polymerase chain reaction. An interesting recent observation has been the apparent protection against autoimmune diseases like rheumatoid arthritis and systemic lupus erythematosus in areas of west Africa where malaria is endemic, in contrast to the high incidence of these in west African-origin Americans. If this is correct, it would be a good example of the old saying that 'autoimmunity is the price paid for eradicating infectious diseases'.

The book is highly recommended despite these remarks.

Tropical Diseases: Molecular Biology and Control Strategies. Sushil Kumar, A. K. Sen, G. P. Dutta and R. N. Sharma, eds. CSIR, New Delhi. 1994. 773 pp.

The prevalence of tropical diseases in India has some very impressive statistics: Forty million people are chronically infected with filariasis, 4 million with leprosy, 0.25 million with Leishmaniasis, 1.5 million tuberculosis cases, 1.0 million malaria cases and equally dreadful number of people with diarrhoeal infection in a year. Rough, probably conservative, estimates these are. As if these diseases are 'inseparable but terrible companion of man' in this country. The urgency to control these diseases cannot be over-

emphasized. Paradoxically, guidelines to control programmes are rather well known. These are chemotherapy, early diagnosis, development of vaccines, eradication of vectors and imparting health education to the community. But nothing could be easier said than done. Effective eradication of tropical diseases poses formidable challenges. There are 'friendly' vectors (mosquitoes, flies) to transmit some 'deadly' diseases like malaria, filaria, kala-azar, encephalitis, etc. Poor hygienic and socio-economic condition add to the misery and severity of the disease. (Parasitic diseases are unfortunately diseases of poor people.) In addition to a plethora of such problems, one is faced with pathogens getting resistant to drugs and vectors to insecticides. The organisms have developed sophisticated survival mechanisms to neutralize host's immune response, to act as 'smoke screen' so that host is unable to elicit protective immunity against the organism. (The process of parasitism is as old as life itself.) Answers to these problems can be found in understanding the fundamentals of host–parasite interactions. It is the belief of many researchers including the present reviewer that new strategies to control tropical diseases can be developed by the application and resources of biomedical sciences to pinpoint new drug targets, to develop diagnostics, to identify and clone protective antigens. It is indeed appropriate that CSIR, as a part of its Golden Jubilee celebration, brought together 250 scientists and research scholars working in tropical diseases for a national symposium held at Central Drug Research Institute, Lucknow (February, 1992), India. *Tropical Diseases—Molecular Biology and Control Strategies* is the title of the book, which consists of 93 papers presented at this symposium.

About half of the book is on filariasis and malaria. Discussion on filariasis begins with a paper on the natural history of infection followed by two papers on immunodiagnosis. The natural course of filariasis, which is a chronic disease, spanning decades needs to be established. The natural course of events starting from infection (bites of mosquitoes carrying infective larvae of the parasites) to the onset of clinical symptoms in humans will undoubtedly be complex, and needs to be studied. A good diagnostic should be able to 'detect' target population (be it asymptomatic microfilaraemic individuals or clinical filarial patients or even individuals 'exposed' to the infection). Early diagnosis of filariasis is a key area linked to control. Present efforts are directed in developing assay systems to detect microfilaraemic carriers. The two papers sum up the progress employing antibody and antigen assays. The latter system detects active infection (presence of parasite) in contrast to antibody assay which in principle cannot differentiate present from past infection. The last words on this difficult subject definitely have not been said. Two papers deal with protective mechanisms in filariasis using animal models. Extension of such studies to humans needs to be initiated. The drugs available for treatment and control of filaria are unsatisfactory and limited. The widely used Diethylcarbamazine lacks adult worm-killing activity, produces adverse reactions in humans, thereby limiting its use for mass therapy. The alternative, Ivermectin, is no better. There is thus a need to synthesize interesting molecules or to identify plant products that could be used as drugs in filariasis. Five chapters are about this subject. Vector control measures either for malaria, or filaria or kala-azar constitute a vital component in tropical diseases research. Four papers discuss this topic. The contents range from application of anti-vector agents in plant extracts, larvivorous fish (*Gambusia affinis*), insecticide impregnated bed nets, insecticides, to even physical removal of weeds (breeding sites) by community participation.

The ability of *Plasmodium falciparum*, the major parasite for human malaria, to overcome anti-malarial drugs is a major hindrance to the control of malaria both in individual and community levels. There are nine papers on the synthesis and mode of action of anti-malarial drugs. Efforts are made from CDRI, Lucknow, to synthesize better derivatives of Chinese drug Quinghasou (Artemesin) against cerebral malaria and new 8-aminoquinoline derivative (CDRI 80/53) against *P. vivax* infection. The biochemistry of malarial parasites and parasitized erythrocytes is a subject of extensive research. A set of eight papers addresses this issue. Enzymes of the parasites have been proposed to be the target of drug design, diagnostic and protective antigens. These assumptions rest on the premise that parasitic enzymes should differ substantially from host (mammalian) enzymes in structural and immunochemical properties. In most cases they are. Antibodies to lactate dehydrogenase of *P. falciparum* were demonstrated as serodiagnostic marker in malaria, polyamine oxidase as potential target for chemotherapy of protozoan diseases. The characterization of lactate dehydrogenase as a possible immunodiagnostic agent indicates an important finding. The production of reactive oxygen species by phagocytic cells is known to be a general defense mechanism against various pathogens. The role of free radicals and lipid peroxidation in malaria has been discussed in two papers. Development of vaccines for malaria with the usual steps of antigen identification, immunogenicity and adjuvant selection is fairly at advanced level compared to other parasitic diseases of man. Two papers report interesting work using synthetic peptides of RESA (ring infected erythrocyte surface antigen) and MSA (major

Microfilariae of human filarial parasite *Wuchereria bancrofti.*

merozoites surface antigens) of *P. falciparum*.

There are six papers on the visceral leishmaniasis or kala-azar. Immunodiagnosis will be highly useful in leishmania, diagnosis of which at present depends solely on biopsy materials. The procedure is painful and inconvenient. DOT-ELISA and direct agglutination tests have been recommended for immunodiagnosis and are discussed comprehensively in three papers. A paper describes the generation of monoclonal antibodies to *L. donovani* whose utility should have been explored. A set of thirteen papers discusses mycobacterial infections, tuberculosis and leprosy. Most of the papers are about the immunodiagnosis. A monoclonal antibody-based assay was described to be useful for diagnosing progressive form of leprosy. Paediatric population is the worst sufferer in any infection, tuberculosis is no exception. It is of interest to note that excretory secretory antigens of *M. tuberculosis* could be used as diagnostic antigen in detecting pulmonary and extrapulmonary tuberculosis in children. The diagnostic utility of ES antigen has parallel in the previous work of this group (Sevagram) in filariasis. A paper reported the lack of production of oxygen radicals from macrophages of leprosy patients and the consequent killing ability; which interestingly can be restored by delipidified cell component of *M. leprae*. Immunology of leprosy is often synonymous with poor delayed type hypersensitivity reaction and immune unresponsiveness. An easily cultivable mycobacterium, *M. habana*, has been reported to break this immunological tolerance. Development of vaccine has been a major focus in leprosy research. Immunotherapeutic potential of much known ICRC (Indian Cancer Research Centre) vaccine has been described in one paper. A single dose of vaccine can significantly upregulated *M. leprae*-specific immune responses in lepromatous leprosy patients.

Seven papers are about micro-organisms (*E. histolytica, Giardia lambia, Vibrio cholerae, E. coli*) that cause diarrhoeal disorders. Papers on the molecular biology of cholera and designing drugs based on molecular mechanism of diarrhoea are noteworthy. There are also two articles on 'ubiquitous' liposomes, as drug delivery vehicle specifically in malaria and in systemic fungal infections. As the role of liposomes in reducing the toxicity of drugs is now well known, its application at least in the later disease and kala-azar may well be accepted for humans in future.

A lone paper on Japanese encephalitis mention the generation of cytotoxic T lymphocytes and the nature of infected cell lysis. A paper on DNA probes describes the usefulness of the technology in detecting infections for *M. tuberculosis*. There are papers on the genetics of antibiotic resistance in pathogenic *A. cinetobacter*, a gram-negative bacteria capable of causing diverse infections and also on human oncogene expression.

The role of traditional medicines (Ayurveda) in the health care of a traditional country like India is very important. A paper describes the activity of plant extracts, selected on the basis of ethenobotanical information, against bacteria (*Klebsiella* sp., *E. coli*, *Shigella flexneri*) causing gastrointestinal and urinary tract infections. Clinical trial of 'Mahakhandaw churna' showed it to be very promising in intestinal amoebiasis compared to metronidazole.

There are some weaknesses which are inevitable perhaps in a book with such a broad range of topics with so many contributors. Some topics (disease) have been dealt reasonably comprehensively, some cursorily. I wonder if the editors could not have organized the papers under sections diseasewise for instance. The book is not free from printer's error either. Nevertheless the editors are to be congratulated for preparing the book which will be an useful addition to the libraries of all laboratories engaged in parasitic disease research. There is something for everyone here.

MEETINGS/SYMPOSIA/SEMINARS

Centenary Seminar on Applied X-Rays

Date: 18–19 December 1995
Place: Madurai

Topics include: Crystal growth and characterization; High-pressure X-ray diffraction; Crystal structures; Defect characterization; Imaging plate technique; Crystalline solid solutions; Other related topics.

Contact: Prof. S. K. Mohanlal
Convener, Centenary Seminar on Applied X-rays
Department of Physics, Madurai Kamaraj University
Madurai 625 021
Phone: 0452-85252
Fax: 0452-85239

DAE Homi Bhabha Chair for Distinguished Scientists/Professors including Engineers and Technologists

The Department of Atomic Energy has established the DAE Homi Bhabha Chair. There would be a total of not more than 8 such awardees of which 4 would be tenable at any of the research centres of the DAE and autonomous institutions aided by it and another 4 at Indian Universities or other academic and research institutions in the country.

Contact: Shri B. K. Saha
Joint Secretary (R&D)
Dept of Atomic Energy
Chhatrapati Sivaji Maharaj Marg
Bombay 400 039
Phone: 022-2022492 (O), 3631987 (R)
Fax: 022-2048476

International Workshop on Advanced Plastics and Rubber Composites (IWAPRC-96)

Date: 15–22 January 1996
Place: Kharagpur

In this workshop, a comprehensive discourse is envisaged on advanced polymeric composites comprising advanced plastics and elastomer matrices, newer fibres, manufacture of composites, mechanics of composites and structure-property, etc.

Contact: Prof. R. P. Singh/Prof. C. K. Das
Materials Science Centre
Indian Institute of Technology
Kharagpur 721 302, India
Phone: (03222) 2221-2224 extn.4792, 7792
Fax: 91-03222-2303
E-mail: rps.matsc.iitkgp.ernet.in

XIV All India Cell Biology Conference of the Indian Society of Cell Biology

Date: 23–25 February 1996
Place: Calcutta

Topics include: Cellular and molecular parasitology; Plant molecular biology and biotechnology; Human diseases: Diagnostics, mechanisms and therapeutic aspects; Animal reproduction and biotechnology; Structure-function of genes and chromosomes and cellular regulation.

Contact: Dr Dwijen Sarkar/Dr Pratap K. Das
Joint Secretaries
XIV All India Cell Biology Conference
Indian Institute of Chemical Biology
4 Raja S. C. Mullick Road, Calcutta 700 032

Fax: 033-473 0350/5197
E-mail: iicb%sirnetc@sirnetd.ernet.in

National Conference on Recent Trends in Vibrational Spectroscopy

Date: 26-28 February 1996
Place: Meerut

Topics include: Vibrational spectroscopy of molecules; Electronic spectroscopy of molecules; Laser and laser-based spectroscopy; Vibrational analysis and molecular structure; Spectroscopic studies and molecular structure; Theoretical methods; Spectroscopy of metal-complexes; New techniques; Other related topics.

Contact: Dr V. K. Rastogi
KC-68/1, Old Kavi Nagar
Ghaziabad 201 002
Phone: 0575-840374
Fax: 011-2413388

Contact Programme for Excellence in Diagrammatics and Cartography in Earth Sciences

Date: 22–29 February 1996
Place: Pune

Topics include: Various aspects of diagrammatics in earth sciences and principles of representations; Computer aided graphics and demonstrations.

Contact: Dr Vivek S. Kale (Local Coordinator)
Department of Geology
University of Pune
Pune 411 007
Phone: 0212-356061 ext. 2115
Fax: 0212-479 306
E-mail: Vivek@unipune.ernet.in

XVIII Conference of the Indian Association for General Relativity and Gravitation (Dedicated to Prof. S. Chandrasekhar)

Date: 15–17 February 1996
Place: Madras

The programme will consist of plenary sessions, special session and sessions for contributed papers covering topics from classical gravity, cosmology, gravitational radiation, relativistic astrophysics, quantum gravity (including strings), etc. There will be a session on the late Professor Chandrasekhar.

Contact: Dr G. Date
Institute of Mathematical Sciences
C.I.T. Campus, Tharamani

All India Institute of Medical Sciences

Ansari Nagar, New Delhi 110 029

Training in Electron Microscopy for Scientific Investigators for a period of 21 days w.e.f. 19.2.96 to 12.3.96

A training programme for a duration of three weeks will be held in the Electron Microscope Facility at the All India Institute of Medical Sciences, Ansari Nagar, New Delhi 110 029.

Applications are invited on plain paper stating the following:

(1) Name, (2) Age, (3) Postal Address, (4) Educational Qualification(s), (5) Name of the University/ Institution graduated from, (6) Positions held with current designation, (7) Whether Permanent/Temporary, (8) A brief write-up on the nature of work and why training in Electron Microscopy is considered necessary, and (9) Letter of recommendation from the present employer. Applications giving the above information should reach Dr A. K. Susheela, Officer-in-Charge, Electron Microscope Facility, All India Institute of Medical Sciences, New Delhi 110 029, **within 15 days of publication this Advertisement.**

A fee of Rs. 3000/- will be charged for the selected candidates. The mode of payment will be indicated in the Letter of Selection.

BIOINFORMATICS PROJECT

SCHOOL OF BIOTECHNOLOGY

MADURAI KAMARAJ UNIVERSITY

Applications are invited on plain paper for the following post in the Bioinformatics Centre, School of Biotechnology, Madurai Kamaraj University, Madurai.

Position: Junior Information Scientist (Technical)
Scale of pay: Rs 2200–4000, with usual allowances

Qualification and Experience

Candidates with a post-graduate degree in Computer Science or Physics or Electronics or Biophysics required. Basic qualification could be relaxed in the case of candidate with exceptional experience.

Knowledge of computer hardware and networking essential. Experience in VAX-VMS, Unix-operating systems and language programming preferred. Familiarity with biology-related software will be an advantage. The candidate will be required to manage the computer systems and maintain and extend the thick ethernet network connectivity VMS, DOS and Unix operating system. The job entails user service-related activities.

The appointment is for the scheme period ending 31 March 1997.

Five copies of the application along with the bio-data should be addressed to the Registrar and marked to the Scientist-in-Charge, Bioinformatics Centre, School of Biotechnology, Madurai Kamaraj University, Madurai 625 021 within fifteen days from the date of this advertisement.

REGISTRAR

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

you're sure to benefit by advertising here.

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers – students, doctoral scientists and professionals in virtually every field of scientific activity in India.

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

Write now, or send your copy to

CURRENT SCIENCE

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

In this issue

Solar photovoltaics

In India as soon as one hears the phrase 'solar energy' the mind slips into a well-oiled groove. Visions of 'appropriate technology' arise. Unwieldy structures of wood and galvanized iron covered with aluminum foil in which blackened vessels are kept to boil rice seem to dot the open countryside. Unfortunately, no low cost method of utilizing solar energy has succeeded commercially. The best way to use solar energy is to convert it to electricity. While cost of photovoltaics as such is a major deterrent worldwide, the lack of the basic technology itself is of major concern in India.

India now seems poised to take its place in the sun. The Central Electronics Limited (CEL) under the Department of Scientific and Industrial Research, Ministry of Science and Technology has made giant strides in the indigenous development of photovoltaic technology. CEL recently won a prestigious international tender against stiff competition from developed countries.

Ashok Parthasarathy has always been a champion of indigenous technology. Under his guidance, both the National Research Development Corporation and the CEL have done a lot to commercialize indigenous technologies for exploitation not only in India but abroad as well. Parthasarathy *et al.* describe in their article (**page 974**) how they traversed the thorny path from the Physics Lab to the state-of-the-art photo voltaics industry.

Amorphous silicon cells cost less but have a low efficiency. Polycrystalline silicon cells are much more efficient but at a much higher cost. Thin film polycrystalline silicon cells show great promise of combining high efficiency with a relatively low cost.

India has a vast potential for tapping solar energy. The efforts of CEL should further us considerably towards achieving this goal.

A. V. Ramani

Mushrooms: Science and myth

Mushrooms, a complex and advanced group of fungi, have been the centre of folklore, legends and magic from time immemorial. They have been a source of misconception and superstition in many a society, probably because of their association with putrescence and decay and because of their often unpleasant colour and fetid smell. As a group, they excel other plants in their sheer diversity of form, smell, colour and function. They have some of the most enviable names such as earth ball, the blusher, the false blusher, lawyer's wig, death cap etc. Botanically the mushrooms that we see soon after a rain, are the fruiting bodies of the fungi. While most of the mushrooms are saprophytic, a few form beneficial association with other plants and fewer still are parasitic.

Amanita muscaria, commonly known as the fly-agaric is one of the most colourful mushrooms and is known for its hallucinogenic property. This mushroom has entered into the folklore and ritual of all major religions. Our own 'soma rasa' is believed to be a cocoction derived from this fungus. In fact the Rigveda contains hymns in praise of this concoction and is said to accurately depict the morphological characteristics of the fly-agaric. However, not all mushrooms impart such intoxication. Many contain nearly fatal toxins, which have been used time and again in history to avenge defeat. Infact on this John Gerard, as early as 1597, warned as mildly as one could 'a few of them are good to be eaten and most of them do suffocate and strangle the eater!' In his article (**page 986**), C. V. Subramanian reviews the fascinating story of these mushrooms blending the science and the myths. A world of opportunity to ponder over and work in these exciting systems is thus unravelled.

R. Uma Shaanker

Current Science on the Internet

The contents pages of *Current Science* have been available on the World-Wide-Web for the last several months. They can be accessed from the home page of the Centre for Ecological Sciences, Indian Institute of Science, Bangalore, using

http://ces.iisc.ernet.in (or http://144.16.65.194).

To go directly to the home page of *Current Science*,

http://ces.iisc.ernet.in/Current Science

can be used. Contents pages for all the issues of *Current Science*, beginning with the 10 July 1995 (up to 10 November 1995) can be found at the site. Also shown are images of the cover pages of 25 August 1995 and 10 September 1995 issues.

There have been over 150 visits to the *Current Science* home page over the last couple of months (excluding those from the many departments within the Indian Institute of Science), for viewing both the contents pages and the cover pages. This includes accesses from Canada, Germany, Sweden, Netherlands, Japan as well as several educational, commercial, governmental and non-governmental organizations in the USA and other parts of the world.

If at all there are any installations which have only ftp access to the internet (and are unable to access the World-Wide-Web), the contents pages can also be downloaded from the anonymous ftp site of the Centre for Ecological Sciences (ces.iisc.ernet.in).

CORRESPONDENCE

A crisis in engineering education

There exists an acute shortage of high-quality teachers in engineering institutions, particularly in the high technology areas. Young talents are not attracted to teaching because of the long drawn process of acquiring the minimum required qualification (a Ph D for IITs, IISc, etc./M Tech for others) and then starting at the same or perhaps a lower salary than what he/she would have got had he/she chosen to join industry immediately after the first degree (B Tech). True, there are exceptions, but they are so insignificant in number that they do not count. Also, even if a young talent joins the teaching profession, the career prospects are rather limited, because the salary of the highest available position in the profession, viz. that of a full professor compares rather poorly with that of a comparable person in industry. This gap has widened, rather than shortened, over the years, particularly in areas like electronics and computers. The situation is such that most of the engineering institutions have to make do with whatever is available in the market, and this is far from being a happy situation. Moreover, adequate manpower, even of questionable competence, is not available so that there exists, always, a significant number of vacant positions in any institution. Obviously such manpower cannot produce high-quality graduates even if the entrants to the courses are of high quality. The process, if allowed to continue, will create, or has already created, a vicious circle. For the advancement of technology, and for technological progress of the country, effective and concrete solutions to the problem must be found and implemented – the sooner, the better!

What constitutes an effective solution? To retain high-quality retiring teachers for a few more years? This has been, and is being tried in many places. But then this is, at best, a temporary measure and cannot be a permanent solution. The obvious solution is to make the teaching profession a very prestigious one – in monetary as well as other terms so that the most talented young people are attracted to this profession, rather than to civil service or industry. Let the level of achievement demanded for the lowest position be high, but let it be justified not only on academic grounds but also in terms of monetary benefits. This will need a substantial change in the attitude of the Government and other funding agencies towards education to the extent that they are willing to allocate to education, a budget which compares not too unfavourably with that of some other important sector (like defence, for example?).

Shortage of good teachers in engineering education has reached a crisis point and this fact deserves serious concern and attention of all concerned.

Vitamin C: A vital nutrient

The review article published by Indu B. Chattejee and coworkers (*Curr. Sci.*, 1995, **69**, 747–751) on 'Vitamin C: A potential saviour against free radical-induced oxidative damage' is really a beautiful one, picturizing the story of an essential nutrient which has varied roles in human nutrition. The article has effectively pointed out the importance of vitamin C and how it functions in order to prevent the various degenerative diseases and aging. Vitamin C is one of the most neglected nutrients in our dietaries. The essential and rich sources of vitamin C are green leafy vegetables and fruits, which are often neglected. In a country like ours where cereal-based diet is the staple one, availability of this vitamin can only be through the inclusion of green leafy vegetables (GLV) and fruits, which has been drastically reduced compared to the earlier days due to the blind emulation of westernized diet patterns, where high-calorie diets play an important role, with relatively low vitamin C content. This is really a disappointing trend as we have rich edible plant diversity, with good vitamin C content. The recent tendency towards animal foods, which are low in vitamin C content, should be checked and ample thrust should be given to the inclusion of GLV and fruits, atleast a minimum of 50–75 g daily, in our food pattern. The best way would be the raw form as far as possible because vitamin C is heat labile and easily destroyed during prolonged heating, to reap the full potential of this vital nutrient.

Indeed the most important reasons for developing many degenerative diseases are improper diet pattern and sedentary life style. But inclusion of the essential nutrients can improve the situation to some extent.

NSU, Academy document and science education: Reflections and an operation model

India, as any other developing country, is passing through a transformation in all spheres of activity. Education, research and the society have much to suffer or get benefited by it. As NRIs, visiting regularly India and maintaining contacts with Indian Universities, we are aware that *suggestions and proposals need to be considered on their feasibility*. Otherwise, we continue debating eternally.

Perhaps our tone of discussion should change and a few specific questions addressed.

1) How competitive do we prepare our youth to face problems and seek solutions?

2) What are the expectations of the industry we are attending to?

3) How good is the output of our research to the society?

4) How much of time do we spend to prepare ourselves to update our own knowledge to pass it on with confidence to the students?

5) How often had we time for self-evaluation and self-criticism?

6) How well can we stimulate youth towards confidence in what they learn and in what they will face in the profession?

7) How much of time do we spend to guide and inspire a student to fetch exciting ideas, and encourage his ideas, without copying them and discouraging them?

8) How can we convince ourselves that we are part of a social upbuilding and that our contribution in our activity is important for the country?

9) How do we solve these problems?

There is no harm in having the input from people and Academies. Only it is necessary to see if they could be feasible *within the existing structure and without prejudicing the ongoing activities in the nation*. Expecting everything from the Government is unrealistic. Thus we also like to give some solutions to one of the ideas, with the hope that our country could forge ahead with its traditional high capacities of talents and creativity.

NSU is feasible

1) Indian science needs reshuffling to activate it further and promote environment for the generation of intelligent ideas and discoveries.

2) This is possible with the feeding in of some new brains and new ideas of action, proposed by an NRI. The spirit behind the idea is to stimulate a supposedly static system in operation and control over Indian science.

3) NRIs are spread all over the world. They love India as others in India do. They also want to contribute to Indian efforts to attain better goals in development. As we see, this is the spirit behind this NSU proposal.

4) Any increase in Universities or Institutes should not interfere in the priorities of the government towards the needs of the large mass of citizens. The fact that all the product of these new Centres of Excellence would revert its genius towards the benefit of the nation, is not doubted, though it is a question of time.

5) It is absolutely feasible to create a group of NSUs spread over India within a short period through the direct involvement of a NRI Foundation.

6) The NRI Foundation will be established in the USA. It will be fed and controlled by the NRIs. Its main activity is to promote the installation, operation and maintenance of the NSUs, one after another in India. Thus NSUs will be Foundation Universities, nonprofit organizations, but operate as Private Institutions. The surplus in the annual budgets will be reverted to NRI Foundation for its activities.

Modus operandi

We are sure that by making proposals within the parameters of their feasibility, all our discussions will be very constructive. Thus we believe that NSUs are absolutely possible and would be very successful. When they adopt a NGO structure, access to the NSUs will be through merit alone.

It is easy to make proposals and offer suggestions. When convinced, it is not difficult to take a lead in trying to make them a reality. (Sometimes theory and experiment are both correct but do not agree with each other; sometimes a wrong theory agrees with experiment. One must therefore be careful not to jump to conclusions[1].) This depends on the desire to succeed, and with a personal commitment. The authors on proposing this NRIF operational system are convinced of its success and thus announce their decision to be among the very first to become Supporting Members of the Foundations.

Nobel leptons

This is the year of the leptons. Of the six leptons of today's particle physics, Nobel Prizes were awarded earlier for discovering two of them: the electron and the muon-neutrino. This year it is the turn of two more leptons, the electron-neutrino and the tau lepton, to acquire 'Nobelity'.

Frederick Reines (University of California, Irvine), aged 77, reported the first direct evidence for the existence of the 'neutrino' in 1956. He performed the experiments jointly with Clyde L. Cowan, Jr., who died in 1974. The neutrino is a tiny neutral particle hypothesized by Wolfgang Pauli, Jr. way back in 1930, and was thought to be unobservable. Twenty five years later and with the invention of the nuclear reactor it was possible to verify the neutrino hypothesis.

Martin Perl (Stanford University, Stanford), aged 68, assisted by a 35-member team, discovered the 'tau lepton' in 1975. This particle carries a unit of electric charge and weighs approximately twice as much as the proton. It is characterized by a short life of only a fraction of a pico-second and has the distiction of being the heaviest and the shortest-lived lepton. It is interesting that while Reines's neutrino results were long hoped for, Perl's tau discovery came as a complete surprise – that too at a time when people were busy establishing the charm flavour around the same mass. The tau lepton heralded the existence of the 'third generation' of fundamental constituents of matter.

A brief history of the neutrino

> The neutrino is the smallest bit of material reality ever conceived of by man; the largest is the universe. To attempt to understand something of one in terms of the other is to attempt to span the dimension in which lie all manifestations of natural law. Yet even now, despite our shadowy knowledge of these limits, problems arise to try the imagination in such an attempt.
>
> F. Reines and C. L. Cowan, Jr.[1].

Neutrino 'was born' in a letter written by Pauli. This historic letter dated 4 December 1930 from Zürich, started with the unusual greeting 'Dear Radioactive Ladies and Gentlemen', and was read out at the Tübingen meeting. Pauli mentioned that he had hit upon the neutrino as a 'desperate remedy' to save, among other things, the principle of energy conservation in beta decay. The letter referred to the hypothetical particle as 'the neutron' (the nuclear constituent ~~neu~~tron was discovered later by James Chadwick in 1932). In Italian the word 'neutrone' means something like 'large neutral one'. It was Enrico Fermi who named the Pauli particle as the 'neutrino', meaning the little neutral one, and that name stuck on.

In 1931 Pauli visited Rome and discussed his proposal of the particle with Fermi who received the idea with 'a very positive attitude'. Official announcement of the neutrino by Pauli was made at the Solvay conference in October 1933, as a particle which possessed no electric charge but carried the missing energy and momentum and escaped the detecting equipment. The famous beta decay theory of Fermi appeared in 1934.

It is interesting that even the great Pauli did not fully recognize the implications of the neutrino, particularly in regard to its penetrating power. His own account of this early period, written sometime in 1957, is extremely fascinating and is now available in English translation[2]. Initially he thought he had done a 'frightful thing' as the neutrino was expected to have penetrating power similar to, or about 10 times larger than, a gamma ray. However in 1934 Hans Bethe and Rudolf Peierls argued that the neutrino had to be even more elusive as its interaction mean free path had to be astronomical in magnitude (note 1).

It was Bruno Pontecorvo who first suggested that the process of inverse beta decay could be used as a way to establishing the neutrino. In 1946 he proposed the celebrated Chlorine–Argon radiochemical method and suggested using the source of reactor neutrinos[2] for the experiment. The Cl–Ar method was taken up almost as a life-long project by the solar-neutrino pioneer Raymond Davis, Jr. (note 2).

Detection of the reactor neutrino

The first neutrino reaction observed (note 3) was the inverse nuclear beta reaction

$$\bar{\nu}_e + p \rightarrow e^+ + n, \qquad (1)$$

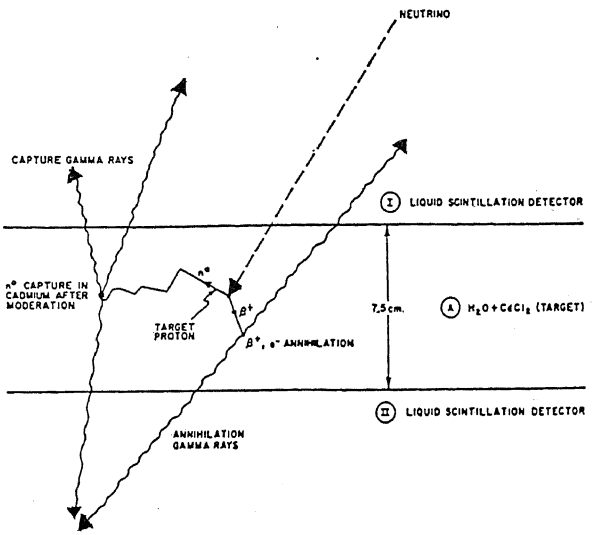
driven by the antineutrinos from the nuclear reactor. This reaction is essentially the reverse of the neutron decay $n \rightarrow p + e^- + \bar{\nu}_e$ from which it is obtainable by transposing the e^- to the left hand side as a e^+ and reversing the reaction arrow. The energy of the incident antineutrino could be deduced from the positron momentum:

$$E_{\bar{\nu}_e} = \frac{E_e + \Delta + [(\Delta^2 - m_e^2)/2M_p]}{1 - [(E_e - p_e \cos\theta)/M_p]} \qquad (2)$$

$$\simeq E_e + \Delta \qquad (3)$$

$$\geq 1.804 \text{ MeV}, \qquad (4)$$

where E_e is the positron energy, p_e is the magnitude of its 3-momentum, θ is the positron emission angle with respect to the antineutrino direction, and $\Delta = M_n - M_p = 1.293$ MeV is the neutron–proton mass difference; the second step ignores neutron recoil terms of order (E_e/M_p) and the last one gives the reaction threshold.



For MeV range of antineutrino energies, the positron angular distribution is nearly isotropic ($\langle\cos\theta\rangle = -0.04$) and the effective cross section may be taken to be (note 4)

$$\sigma = \frac{4G_F^2}{\pi} p_e E_e, \qquad (5)$$

where G_F is the Fermi coupling constant; for $E_{\bar{\nu}_e} = 2.3$ MeV the cross section is

$$\sigma \simeq 6\times10^{-44} \text{ cm}^2. \qquad (6)$$

The idea underlying the Nobel Prize-winning experiment was to look for a pair of scintillator pulses, the first (prompt) pulse due to positron annihilation and the second (delayed) one due to capture of the moderated neutron. The experiment[3] was performed around 1955–56. The projectiles were the reactor neutrinos from the Savannah River Plant located in South Carolina State, USA, and targets were the protons in a solution of water mixed with cadmium chloride (Cd is a good absorber of thermal neutrons). The experimental apparatus could be viewed as a multiple-sandwich with 2 layers of cheese (target material) arranged between 3 pieces of

Schematic diagram of neutrino detector.

Figure 1. Schematic diagram of the neutrino detector of Reines–Cowan experiment[4].

bread: the cheese layers were the two target tanks containing a solution of water and $CdCl_2$, while the bread pieces were the three liquid scintillator detectors.

An event meant the detection of two prompt coincidences (see Figure 1): the first one was between the two photons (each having 0.511 MeV energy) of the positron annihilation, and the second prompt coincidence was due to the capture of neutron by cadmium giving a few photons (with total energy of 9 MeV). The second pulse occurred after several micro-seconds of the positron flash, the time it took for the neutron to be thermalized in the target water. The experiment involved, among other things, measuring the energies of the pulses, their time-delays, dependence of event rate with neutrino flux which varied with the reactor power output, etc.

The results were published in the 5-author paper C. L. Cowan, Jr. *et al.*[3] entitled 'Detection of the Free Neutrino: A Confirmation'. This paper, unusual for the lack of diagrams of the detector or the customary figures or tables, is regarded as the discovery paper (note 5). Photographs of the detector assembly and associated equipment can be seen in ref. 4. The observed signal varied with the reactor-power. It consisted of an average rate of 2.88 ± 0.22 counts/hour, consistent with a value $\sim 6 \times 10^{-44}$ cm^2 for the inverse beta-reaction cross section. The signal to reactor-unrelated background ratio was 3 to 1.

It is remarkable that in the same year Reines and Cowan[1] also gave an upper limit on the neutrino magnetic moment,

$$\mu_{\bar{\nu}_e} < 10^{-9} \mu_B,$$

where μ_B is the Bohr magneton. This limit was deduced from the extent of non-observation of scintillator pulses along the path of the reactor neutrino, and is about the same as the present upper limit which is extracted by using different considerations (for a survey of the recent results in neutrino physics, see e.g., ref. 5).

Even today, we do not know very much about the electron-neutrino (and much less about other neutrinos). As for its mass, data on the end-point of the beta electron spectra only show that it does not exceed a few eV; a recent high statistics experiment[6] using molecular tritium in gaseous form, gave the upper limit

$$m(\bar{\nu}_e) < 4.35 \text{ eV}, \quad (7)$$

at 95% confidence level.

Experimental data with ν_es are not extensive because it is difficult to obtain ν_e beams. At the pi-meson factories, low energy ν_e get produced in 3-body decays and along with muon-neutrinos (ν_μ and $\bar{\nu}_\mu$). Sun is no doubt a good source of ν_e but solar neutrino fluxes are not well understood and constitute one of the challenging problems of current research. Only recently the first experiment using a man-made source of pure ν_e was performed. It made use of an intense source of reactor-produced ^{51}Cr (which emits ν_e by electron capture) to calibrate the GALLEX solar neutrino detector[7].

Discovery of the tau lepton

The tau lepton broke on the scene unexpectedly. While the results of Reines needed the construction of power reactors, the discovery of tau lepton needed high energy electron–positron colliders. Tau lepton is the third kind of charged lepton that exists in Nature, the other two being the electron and the muon. (The Greek letter τ is the first in the word triton, meaning third). Its birth can be traced to the 1975 paper entitled, 'Evidence for anomalous lepton production in $e^+ - e^-$ annihilation' by Perl *et al.*[8].

The experiment was performed at the electron–positron collider called SPEAR (Stanford Positron Electron Accelerator Ring). At this facility, beams of e^- and e^+ were accelerated simultaneously in opposite directions in a ring and made to intersect. As the total center-of-mass energy (the sum of beam energies)

$$E_{cm} = E_{e^-} + E_{e^+} \quad (8)$$

$$= 2E_{e^-}, \quad (9)$$

was tunable in the range 3–8 GeV, a pair of charged particles each having a rest mass of about 2 GeV could easily be produced at SPEAR.

A large cylindrical detector placed in a magnetic field surrounded the collision area. Electrons were identified by the electromagnetic shower counters, and muons by their ability to penetrate large amounts of iron and other materials making up a total of 1.7 absorption lengths for pions. Particles emitted at polar angles between 50° and 130° and at all azimuthal angles were recorded.

Anomalous events. The 'anomalous' events reported by Perl and collaborators corresponded to the following reactions which had a very distinctive signature,

$$e^- + e^+ \rightarrow e^- + \mu^+ + \text{i.p.}, \quad (10)$$

$$\rightarrow e^+ + \mu^- + \text{i.p.}, \quad (11)$$

where 'i.p.' denotes invisible particles which left no trace in the detector. The ingenuity of the experimenters consisted in establishing that the oppositely-charged $e\mu$ pair arose from the separate decays of two new particles which were oppositely-charged and short-lived. In an effort to reduce the background due to the copious production of e^+e^- and $\mu^+\mu^-$ pairs, the events were chosen to be 'acoplanar' so that production of more than two particles was ensured. For this the μ was required to make an angle more than 20° to the plane that contained the final e and the incident beam.

The very first report of Perl *et al.*[8] had a total of 64 anomalous events at the SPEAR range of energies. For example, at the energy $E_{cm} = 4.8$ GeV there were 24 events (13 $e^+\mu^-$ and 11 $e^-\mu^+$) with an estimated background consisting of about 5 events (arising from possible misidentification of hadrons as leptons, decays of known hadrons into leptons, etc). The events were found to be 'noncollinear', meaning that the angle between the e and μ momenta was more than 90° and the two particles were emitted in opposite hemispheres with respect to the beam.

Threshold behaviour. The occurrence of anomalous events as a function of E_{cm} exhibited an increase around 4 GeV, as shown in Figure 2. This indicated the existence of a threshold for the production of anomalous events. Moreover, in producing a pair of point-particles $\tau^+\tau^-$ by one-photon exchange

$$e^+ + e^- \rightarrow \gamma_{virtual} \rightarrow \tau^+ + \tau^-, \qquad (12)$$

quantum electrodynamics tells us that the total cross section $\sigma_{\tau\tau}$ should depend on the final velocity β as follows:

$$\sigma_{\tau\tau} = \frac{(3-\beta^2)}{2}\beta\sigma_0 \quad (\text{for spin } \tfrac{1}{2}), \qquad (13)$$

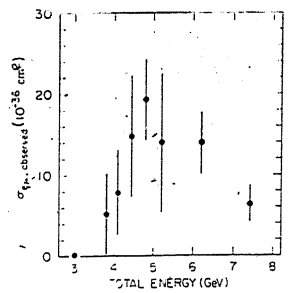


Figure 2. The observed cross section for the anomalous e–μ events[8].

$$= \frac{\beta^3}{4}\sigma_0 \quad (\text{for spin } 0), \qquad (14)$$

where

$$\beta = \sqrt{1 - \frac{4M_\tau^2}{E_{cm}^2}}; \quad \sigma_0 \equiv \frac{4\pi\alpha^2}{3E_{cm}^2}; \quad \alpha \simeq \frac{1}{137}. \qquad (15)$$

In the boson case, the β^3 dependence arises from the p-wave production which is a result of parity conservation in electromagnetic interactions. Subsequent experimental observations were consistent with a linear rise of the cross section with velocity and thus for the $\tau^\pm$ the assignment of spin $\frac{1}{2}$ was preferred over spin 0 and other possibilities.

Final interpretation of the anomalous events followed soon[9]: electron–positron annihilation gives rise to a pair of tau leptons

$$e^+ + e^- \rightarrow \tau^- + \tau^+ \qquad (16)$$

which decay immediately into lighter leptons. The 'tau–lepton number' conservation is respected by assuming the emission of an associated neutrino called the tau-neutrino (ν_τ) in the τ^- decay, and a tau-antineutrino ($\bar{\nu}_\tau$) in the τ^+ decay. Thus to explain the anomalous event with, say, $e^-\mu^+$ we should appeal to the decays

$$\tau^- \rightarrow e^- + \bar{\nu}_e + \nu_\tau, \qquad (17)$$

$$\tau^+ \rightarrow \mu^+ + \nu_\mu + \bar{\nu}_\tau, \qquad (18)$$

wherein the two neutrinos and the two antineutrinos (belonging to all three neutrino generations) constitute the invisible particles.

Data gathered over the years have shown that the shape of the electron (and also muon) energy spectrum in tau decay is in good agreement[10] with the standard V–A theory. Also all the observations support the view that the e–μ universality is extendible to e–μ–τ universality. Thus the original enigma regarding the existence of muon is deepened. It now becomes the so-called 'generation puzzle': among the ultimate constituents of matter, why do members of one generation behave exactly in the same way, except for mass, as the corresponding members of another generation?

It may be interesting to recall that in 1974 the spectacular discovery of J/ψ (3.097 GeV) immediately brought forth in its wake an intense frenzy of activity relating to the charm flavour. People were busy studying the spectroscopy of hidden-charm states and open-charm states and their decays. Consequently the feeling prevalent at the time was that Perl's anomalous events were some obscure manifestation of charm decays and the situation would be clearing up soon. However such feelings were firmly dispelled by 1977 when the Double Arm Spectrometer (DASP) group[11] working at DESY, Germany, reported seeing the anomalous $e\mu$ events around ψ' (3.686 GeV) manifestly below the open-charm threshold (2×1.87 GeV).

The present best value for the tau lepton mass comes from the measurements at the Beijing Electron Positron Collider (BEPC)[12], and is given by

$$m_\tau = 1776.96^{+0.18+0.25}_{-0.21-0.17}\ \text{MeV}, \qquad (19)$$

where the first error is statistical and the second systematic. The relatively large mass of the tau implies a large phase space for decay, and this makes a variety of final states to be accessible for the tau decay. Some of the decay states contain 5 charged particles (pions or kaons) besides the missing tau-neutrino and possibly one or two neutral pions. The availability of several competing channels for decay (e.g., the relative decay probability for $\tau^- \rightarrow \pi^- + \nu_\tau$ is $(11.7 \pm 0.4)\%$), makes the tau a very shortlived particle. Its meanlife is presently known to 1% accuracy[13],

$$\tau_\tau = (2.956 \pm 0.031) \times 10^{-13}\ \text{s}. \qquad (20)$$

Finally, in regard to the mass of the tau-neutrino, the information available is very limited: the mass limit obtained from a recent study[14] of the tau-decay events each containing 5 charged pions is, $m(\nu_\tau) < 24$ MeV at 95% confidence level.

Summary

The announcement of this year's Nobel award in Physics is in recognition of two landmark experiments in elementary particle physics. One provided the first confirmation of the neutrino, as envisaged by Pauli more than two decades earlier, as a tiny neutral particle emitted in beta decay. The experiment made an ingenious use of time-correlations of scintillator pulses to ascertain the occurrence of the inverse scattering reaction.

Table 1. Lepton generations

Generation	Lepton	Discoverer(s) (year)	Nobel Prize winner(s) (year)
1	electron, e	J. J. Thomson (1897)	J. J. Thomson (1906)
	electron-neutrino ν_e	C. L. Cowan *et al.*[3] (1956)	F. J. Reines (1995)
2	muon μ	J. C. Street, E. C. Stevenson; C. D. Anderson, S. H. Neddermeyer – (1936)	
	muon-neutrino ν_μ	G. Danby *et al.*[16] (1962)	M. Schwartz, L. M. Lederman, J. Steinberger (1988)
3	tau τ	M. L. Perl *et al.*[8] (1975)	M. L. Perl (1995)
	tau-neutrino ν_τ	?	?

The other experimental investigation which shared this year's honour is the discovery of the heavy charged lepton τ. This was a serendipitous discovery perhaps like that of the muon. The 'anomalous' events with the oppositely-charged e and μ were interpreted as resulting from the independent decays of the shortlived pair $\tau^+\tau^-$ which was created in the reaction $e^+ + e^- \rightarrow \tau^+ + \tau^-$ The τ is a member of the third (and perhaps the last) generation of ultimate constituents of matter to which the top and bottom quarks belong (see e.g. ref. 15).

A summary of the discoveries made in the world of leptons is given in Table 1. We see that the third generation has started getting Nobel prizes. It is amusing that the charged-leptons crop up with a 39-year gap and may be the 4th one would show up in the year 2114. For the present, the available experimental information implies that there are no charged leptons which are heavier than the tau and lighter than 45 GeV.

Finally it should be emphasized that the third kind of neutrino ν_τ still needs to be identified experimentally (this is shown by question marks). To this end one ought to demonstrate that τs are produced directly in collisions of the ν_τ with nuclear targets. However ν_τ beams are hard to obtain mainly due to the short intrinsic lifetime of the τ.

Notes

1. For the case of reactor antineutrinos going through water, taking the cross section to be $\sigma(\bar{\nu}_e + p \rightarrow e^+ + n) \sim 6 \times 10^{-44}$ cm^2 and noting that there are two free proton targets per water molecule, the interaction mean free path will be $\lambda = (1/n\sigma) \simeq 2.5 \times 10^{20}$ cm $\simeq 260$ light years!
2. It is worth recalling that the Cl–Ar experiment of Davis performed in 1956 at the Savannah River Plant reactor was a 'failure'. The result was not clearly inconsistent with background. The null result $\sigma(\text{reactor } \nu + {}^{37}\text{Cl} \rightarrow e^- + {}^{37}\text{Ar}) < 0.9 \times 10^{-45}$ cm^2 was interpreted to demonstrate that the reactor neutrino is not ν_e but $\bar{\nu}_e$. Since $\bar{\nu}_e$'s are emitted in the beta decays of neutrons and neutron-rich nuclei, a fission reactor is an abundant source of $\bar{\nu}_e$.
3. Here as is customary the word 'neutrino' is being used in its generic sense although, strictly speaking, what Reines and his group detected were the signals from the electron–antineutrino $\bar{\nu}_e$.
4. At MeV energies this has an approximate quadratic dependence on the incident neutrino energy E_ν; at higher energies (above GeV) it becomes independent of E_ν due to the rapid decrease of the vector and axial-vector form factors. However the total cross section increases linearly with E_ν, as a consequence of the point nature of the target quark. At still higher energies (where the W mass effects become important) the total cross section is expected to increase logarithmically, as is indicated in the recent HERA experiments $ep \rightarrow \nu_e + \ldots$.
5. The earlier 1953 experiment of Reines and Cowan, *Phys. Rev.*, 1953, **90**, 492; **92**, 830) performed at the Hanford reactor in Washington, did not give a signal well above the background that was unrelated to the reactor. The number of delayed coincidences had a large uncertainty, 0.41 ± 0.20 per hour.

Rice Biotechnology – Report on the Third International Rice Genetics Symposium October 16–20, 1995, Manila, Philippines

The Third International Rice Genetics Symposium was held at Manila, Philippines from October 16–20. The symposium was organized by the Rice Genetics Cooperative, International Rice Research Institute (IRRI), Los Banos and supported by the Rockefeller Foundation. IRRI has been organizing the rice genetics symposia every five years since 1985. In the last 12 years the Rockefeller Foundation has been intensively supporting rice biotechnology research with an investment of 65 million dollars. These funds have supported rice biotechnology research in the Asian countries as well as encouraged the advanced plant molecular biology laboratories in Europe and USA to take up research on rice. Further close linkages between the laboratories in the developing and developed countries have been established. As a result, rice plants are now grown in glass houses, with the backdrop of the Alps, in Switzerland and rice research is carried out at Cornell and Wisconsin Universities in USA and at John Innes Centre, Norwich and the University of Birmingham (UK). Japan has invested heavily in the Rice Genome Research Programme. China has a modest Rice Genome Programme besides a large number of laboratories engaged in rice biotechnology. This investment in rice has resulted in the blooming of rice biotechnology. This was clearly visible in the symposium with over 500 participants and over 300 oral and poster presentations. A marked shift towards molecular biology approaches was evident in comparison to the previous two symposia held in 1985 and 1990. In fact, at the concluding session, the participants were reminded by Ralph Riley that molecular biology only provided additional, new tools to be used by the plant breeders to facilitate their work of developing more productive, stress-tolerant cultivars with better enduse qualities.

Papers were presented in the areas of rice genome characterization, genetic transformation of rice, molecular tagging and map based cloning, gene isolation characterization and expression, quantitative trait loci (QTL) mapping, molecular cytogenetics, molecular analysis of cytoplasmic male sterility, genetic diversity in pathogen populations, genetics of morphological, physiological, disease resistance and quantitative traits. Gene mapping and transformation emerged as the two dominant areas of current world-wide interest in rice biotechnology.

Among the cereals, rice happens to have the smallest genome size and this has made it an ideal material for molecular biology studies and biotechnology. Restriction fragment length polymorphism (RLFP) technology was applied initially in the rice genome mapping but now polymerase chain reaction (PCR) based markers are being increasingly used. It was reported that 1904 markers consisting of cDNA clones as well as RAPD markers have been mapped covering a distance of 1590 cM. Integration of cytological, conventional and RFLP linkage maps was reported resulting from correct orientations of the maps with respect to each other.

Synteny (similar arrangement of genes along the chromosomes) between rice and wheat chromosomes was reported earlier. This has been further confirmed now and extended to barley, maize, sorghum, sugarcane, foxtail millet, pearl millet, oats and ryegrass. This makes the cloned and mapped genes of rice extremely useful for isolating and mapping genes in other cereals and should provide a quantum leap for molecular biology of other cereals.

Conversion of cloned RFLP markers of the Cornell University – IRRI genetic map to sequence-tagged sites (STS) was reported. The use of STS facilitates the breeding programmes by way of speed, convenience, reliability and relatively low cost as the PCR methods are used for analysis. Marker-assisted breeding would greatly facilitate selection for insect and pathogen resistance and in pyramiding of resistance genes.

Early results on association between molecular markers and quantitative trait loci (QTL) which determine the components of yield and ultimately the yield were reported. Such markers can assist in evaluation of the germplasm, selection of parents-to-be used in hybridization programme, prediction of hybrid vigour and in making selections.

A large number of reports were presented on the transfer and expression of alien genes into rice providing resistance to insects, viral, bacterial, and fungal diseases and nematodes. Reliable *Agrobacterium* mediated and gene gun methods have been developed. For insect resistance synthetic, codon optimized Cry 1A(b), Cry III A, from *Bacillus thuringiensis*, soybean trypsin inhibitor, cowpea trypsin inhibitor, potato proteinase inhibitor (pin 2), snow drop (*Gallanthus nivalis*) agglutinin (GNA) and ribosome in activating protein; for virus resistance, rice yellow mottle virus coat protein, hoja blanca virus (RHBV) and tungro virus, chitnase and cercosporin B gene for fungal diseases and herbicide resistance *bar* gene; and the gene for glycene betaine synthesis to provide salinity stress tolerance have been transferred to rice. Stability and expression of some of the transferred genes have been checked in the progenies upto the fifth generation. Time from the transformation event to obtaining the transformed plants and harvest of seeds from such plants have been considerably shortened. Approximately 11 weeks to obtain plantlets and less than a year for harvesting seeds were reported. Transformed plants are under glass house evaluation and are expected to move out into the field shortly. Insertion of single copy of the gene at one site, or multiple copies at one site as well as single or more than one copies at multiple sites have been observed.

In one presentation, transfer of rice clones encoding proteins from MADS-domain were transferred and expressed in tobacco where they altered apical dominance resulting in early flowering and bushy plants. Expression of Os-MADS3 altered floral organ development and homeotic development of petals to stamen. These results establish that the regulatory factors for flowering in dicots and monocots may be similar. Such homeotic genes have been extensively investigated in *Arabidopsis*.

The other significant reports described efforts made towards cloning of blast resistance genes by chromosome walking, presence of transposable elements in rice as well as in the pathogen

for blast disease, encoding of a receptor-like protein kinase by disease resistance gene, molecular analysis of anthocyanin pigmentation pathway, manipulation of starch metabolism during seed development, characterization of mitochondrial genome, silencing of β-glucuronidase gene in transgenic rice.

It has been projected that by the year 2025, the global demand for rice would increase by 70%, requiring production of 810 million tons of unmilled rice compared to the present production of 480 million tons. This will have to be harvested from diminishing cultivated area and availability of water due to competing demands on these resources. It was repeatedly emphasized that to meet this demand the rice yields will have to increase from the present mean of 4.5 tons ha^{-1} to 8.0 tons ha^{-1} under irrigation and from 1.9 tons ha^{-1} to 3.6 tons ha^{-1} in the rainfed areas. This will have to be achieved by increasing the yield ceiling, bridging the gap between the potential and the realized yield and sustaining the present levels. The major role of biotechnology towards this goal would be in the development of transgenic plants with resistance to biotic and abiotic stresses. Therefore there is an urgent need to evolve procedures for field releases of transgenic plants and approval of grain harvested from such plants as safe food similar to those produced using conventional genetic tools. The marker-assisted selection and tissue culture methods would facilitate breeding programmes and reduce the breeding cycle time.

RESEARCH NEWS

Designer molecules: A chromogenic sensor of creatinine

Uday Maitra

Specific recognition of molecules by one another via shape complementarity and specific, weak non-covalent interaction like hydrogen-bonds, van der Waal's interaction, etc. is central to biology. Recognition of a chosen guest by specifically designed host molecules is currently a major area of chemical research.

Molecular and ionic sensors have always been in great demand for the easy detection/assay of a variety of molecules and ions[1]. Such sensors find many applications in medical diagnostics and in detecting environmental pollutants. A variety of chemical sensors, including biosensors, can be designed[2]. However, sensors based on synthetic molecular receptors are becoming more attractive since such molecules are usually much more stable compared to biomolecules. Of sensors, chromogenic sensors are the most valuable ones since the presence of the 'guest' is signalled by a change in colour. A number of chromogenic sensors have recently been designed and synthesized based on the principles of molecular recognition[3].

In a recent communication to *Science* (1995, **269**, 671), Bell and coworkers have designed a receptor which detects creatinine efficiently. Creatinine is one of the end products of nitrogen metabolism, and in healthy human beings it is excreted in the urine. The transport of creatinine from the blood to urine is mediated by the kidneys, hence the blood level of creatinine is a key indicator of renal function. Present methods available for the assay of creatinine are tedious and expensive. Bell's work has produced a simple but sensitive assay of creatinine, in which the formation of a supramolecular complex is signalled by a colour change.

The H_2N–C=N moiety of creatinine has a D-D-A array* for forming hydrogen bonds. The designed receptor however, in its neutral form, has a D-A-A surface for forming an H-bond. However, a zwitterionic structure is also possible for this receptor, in which the phenolic hydrogen is transferred to the nitrogen atom at the other end of the molecule, thereby converting the D-A-A surface to an A-A-D surface which is now complementary to the creatinine surface. In other words, of the two tautomeric forms only the zwitterionic form (the 'dye'-like form) should bind creatinine. In this example, that is what happens – the receptor exists predominantly in its neutral form, say in dichloromethane solution, which has a yellow colour. However, when this solution is shaken with an aqueous solution of creatinine, the receptor extracts creatinine into the organic solution, forms the complex, and in that process undergoes a change from the neutral to the zwitterionic form. This causes a colour change from yellow to brownish orange (the complex shows an extra absorption band at λ_{max} = 444 nm). This is schematically shown in

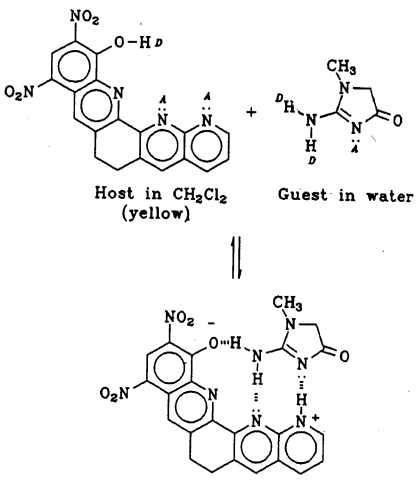

Figure 1

*D and A stand for donor and acceptor groups for forming a hydrogen bond, respectively.

Figure 1. The authors have also carried out X-ray structural analysis of the receptor, creatinine, and the complex to demonstrate some of the finer details of the binding.

The authors have shown that this synthetic receptor is selective for creatinine, since no colour change was observed with creatine, urea, uric acid, proline or histidine. The estimated dissociation constant of the complex (0.5 μM) is also sufficiently low so that blood serum creatinine (typically 40–130 μM) can be sensed by it. Alkali metal ions were found to give some chromogenic response with the receptor, but those were significantly weaker. The prospects for the use of synthetic receptors in medical diagnostics are bright.

Pathogenesis: Generating new paths in understanding bacterial virulence

Kakoli Mukhopadhyay

The survival strategy of bacterial pathogens requires establishment in a suitable niche within another living organism, outwitting it by avoiding its formidable immune system, acquiring nutrients from it and multiplying, thus causing disease in the host. The host–pathogen interaction is a battlefield where the infecting organism encounters a range of adverse environmental conditions. These, along with other selective pressures, appear to have directed the evolution of specialized regulatory systems controlling the expression of virulence factors in the pathogen. To understand mechanisms by which the bacterial parasites circumvent or avoid the immune system of the host and cause disease, it is necessary to identify and characterize the bacterial genes and gene products responsible for the virulence at each stage of the development and progression of the disease. Traditionally, the strategies for identification of virulence factors included the three following approaches:

(1) Brute force screens, that pinpoint the virulence genes on the basis of mutational loss of a virulence phenotype[1,2].
(2) Cloning screens, that pick up novel virulence genes depending on their ability to confer a virulence-associated phenotype in a heterologous bacterium[3].
(3) Regulatory screens, that identify potential virulence genes by their coordinate expression with other known virulence genes under defined laboratory conditions[4,5].

All these strategies, carried out *in vitro* were, however, very often limited by their inability to reproduce accurately the complex and changing environments encountered by the pathogens in their hosts. Moreover, there could also be certain factors which would be induced only under specific environments within a host and could never be expressed, or were expressed in extremely low and negligible amounts, *in vitro*. Therefore it remained quite possible for one to miss out these genes if only the traditional methods were followed.

To overcome these limitations, Mahan *et al.*[6] developed, in 1993, a novel genetic system, which they termed '*in vivo* expression technology' (IVET). What made this strategy unique was their use of simple laboratory techniques to randomly choose genes (or only their promoters) from virulent pathogens, induce their expression within the host (i.e. *in vivo*), and then compare this with their expression *in vitro*. This then allowed them to select for those genes which were transcribed better or exclusively so only in the presence of the host environment. This, in fact, was the first attempt to study the induction of pathogenesis-related genes in the actual host environment conducive to disease development.

The first step in the technique consisted of the selection of a bacterial cell with a mutation in a biosynthetic pathway gene that greatly attenuated growth *in vivo*. For this purpose, Mahan *et al.* used a purine auxotroph (*purA*) of *Salmonella typhimurium*. Growth of such a strain *in vivo* was possible only if a wild-type *purA* gene could be introduced into it. A plasmid (pIVET1) was constructed by inserting a fusion of the wild-type *purA* gene with a marker gene (in this case, *lacZY*) into a broad host-range suicide vector (pGP704). The chromosomal DNA of *S. typhimurium* was fragmented by a specific restriction enzyme and cloned into the plasmid pIVET, 5′ to the *purA-lacZY* operon, thus giving rise to a transcriptional fusion where a *S. typhimurium* promoter would drive the transcription of a wild-type *purA-lacZY* fusion. A pool of pIVET1 containing these transcriptional fusion constructs was introduced into purine-deficient *S. typhimurium* cells.

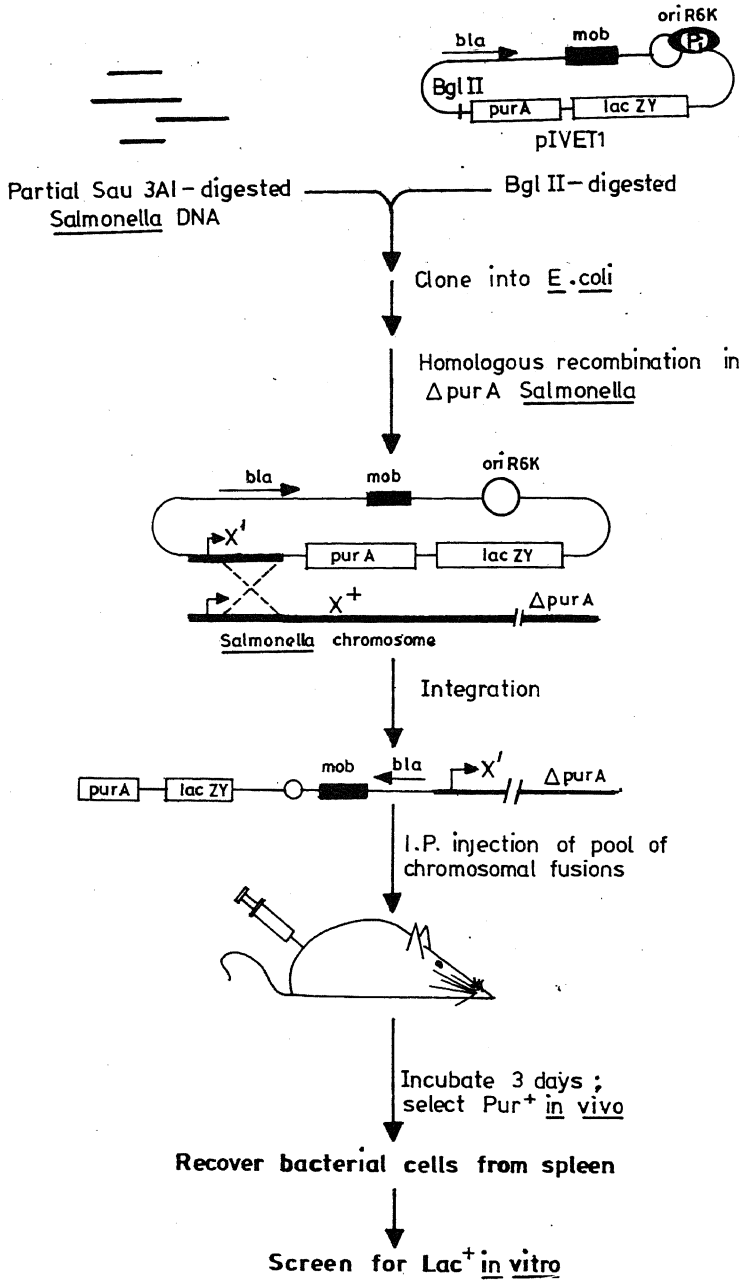

Figure 1. A schematic representation of the technique for the selection of *ivi* genes from *Salmonella*. Sau 3AI, Bgl II: restriction endonucleases (from Mahan *et al.*[5]).

Selection for ampicillin-resistant bacterial cells now enabled the identification of those in which the pIVET1 had integrated into the bacterial chromosome by homologous recombination with the cloned *S. typhimurium* DNA present on the plasmid (Figure 1). Thus, in these cells, the level of *purA* expression required to supplement the parental purine auxotrophy should logically correspond to the level of *lacZ* expression that would, in turn, give a Lac^+ phenotype. Only 33% of the cells grown *in vitro* showed Lac^+ and the corresponding $PurA^+$ phenotype. A pool of these recombinant bacteria were injected intraperitonially into a BALB/c mouse. The surviving bacterial cells were isolated from the spleen after three days and this procedure repeated once more. The cells that could overcome the purine deficiency due to the presence of the integrated *purA* gene were expected to survive and multiply in the mouse. The cells recovered from the spleen indeed showed an increase in their number (86%) compared to that in the initial inoculum. However, there were also a group of cells, though very small in number (5%), which showed a Lac^- phenotype in artificial medium. The question that naturally arises here is how could these cells manage to survive in spite of a very low probability of doing so. A reasonable explanation could be that the promoter that drove the *purA-lacZ* fusion gene in these cells could be turned on only *in vivo* and not under laboratory conditions. Therefore, the genes that were regulated by these promoters under natural conditions were aptly termed as '*in vivo*-induced' (*ivi*) genes. This phenomenon was confirmed by assaying β-galactosidase activity in the bacterial cells recovered from the spleen and comparing it with that of the same strain grown overnight in the laboratory, on enriched medium. In all the cases tested, the activity was actually 40 to 1000-fold greater in the cells grown *in vivo*.

The next step included the selection, cloning and sequencing of some of the *ivi* genes identified by the above technique. Sequence analysis could classify 15 of these genes into 5 different classes. Two of these turned out to be previously unknown genes with no homology to sequences in an established gene bank. These genes had probably not been identified earlier due to their inability to express *in vitro*. The other 4 genes included a *carAB* operon, a *pheST himA* operon and a *rfb* operon. The former consists of genes coding for two subunits of carbamoylphosphate synthase, an enzyme involved in arginine and pyrimidine biosynthesis. The low availability of pyrimidine in the animal tissue was obviously the force driving the induction of these genes. The IVET, in this case at least, helped in the identification of genes involved in intermediary metabolism and whose induction appeared to be necessary for the survival of the pathogen in the host tissues. The *pheST himA* operon is known to encode two subunits of phenylalanine tRNA synthetase and one subunit of the integration host factor (IHF). The latter is a DNA-binding protein required for essential functions like DNA replication, gene regulation and site-specific DNA recombination. The IHF has also

been implicated in regulating the expression of typel pilin (a protein conferring on *S. typhimurium* the ability to prevent clearance from animal tissues). A third fusion, the *rfb* operon, encodes approximately 20 genes involved in the synthesis of O-antigen (the outermost layer of lipopolysaccharide of *S. typhimurium*).

The ultimate goal of the experiments done by Mahan *et al.* was to identify the *ivi* genes involved in pathogenesis, which were otherwise not being picked up by the traditional techniques. Mutant strains, defective in *ivi* expression were then constructed to test their overall contribution to pathogenesis. These mutants, as expected, showed significantly less expression of the *lacZ* gene. This was also accompanied by a marked decrease in virulence as observed by a 2×10^4-fold increase in the lethal dose. Moreover, virulence was so diminished that mice could even be immunized with these mutant strains and rendered resistant to infection by *S. typhimurium*, administered orally.

Many other pathogenic bacteria are known to be attenuated by purine auxotrophy[7–11]. This technology can therefore be useful in studying a variety of host–pathogen systems. Various other biosynthetic genes can also be used for this selection scheme. One such example is a *thyA-lacZY* fusion construct which could be used in bacterial strains with thymine auxotrophy resulting in their attenuation. The advantage of this system is the easy selectability of thyA$^-$ mutants with trimethoprim.

A drawback of the IVET was its applicability only in host–pathogen systems where attenuating auxotrophies prevailed. However, earlier this year, Mahan *et al.* expanded the scope of this technology by developing a transcriptional fusion vector using antibiotic resistance as the basis for selection in host tissues[12]. This new vector contains a fusion of promoterless chloramphenicol acetyltransferase (*cat*) and *lacZY* genes. BALB/c mice were infected with a pool of *S. typhimurium* clones carrying random cat–lac transcriptional fusions and were subsequently given intraperitoneal injections of chloramphenicol. The strains which survived the passage through the animals expressed the *cat* gene and were then screened for those that had low-level *lacZY* expression on laboratory medium. These strains would carry fusion constructs containing specific *ivi* genes. A major advantage of the antibiotic-based IVET selection is that it does not require the isolation and characterization of an attenuated mutant strain with a genetically defined nutritionally-deficient species as in the original IVET protocol[6]. Thus, the antibiotic-based IVET selection should also be applicable to fastidious organisms where genetic markers, suitable for nutritional IVET schemes, are not readily available. Subtractable hybridization could be one way of identifying or estimating the expression of *ivi* genes of these microorganisms[13]. But the extremely low quantity of bacterial RNA produced in the host tissues could pose a limitation in achieving this.

One of the most challenging environments that invading bacteria encounter within the host is the host macrophages which eliminate the pathogens in the majority of cases. *S. typhimurium*, however, is an exception in that it has evolved mechanisms to survive within the inhospitable environment of the phagolysosomes. Genes of this organism, which are specifically induced in cultured macrophages, could also be isolated by the IVET. Characterization of the *ivi* genes of *S. typhimurium* in macrophages would help in tracing the unique mechanism by which this pathogenic species survives the unfavourable host environment.

With the introduction of antibiotic-based selection of *ivi* genes, the IVET can be extended to a broader host/host–pathogen range, thus opening up the possibility of studying a larger number of genes involved in various metabolic pathways in greater detail. Such studies may give us an insight into the underlying mechanisms regulating the development of different diseases and thus provide clues for the design of specific drugs against them.

COMMENTARY

Are herbaria redundant?

R. R. Rao

In the current era of biotechnology and molecular biology the classical subjects like the taxonomy and herbarium have witnessed a great debacle. Unless immediate measures are taken to restore the herbaria and associated taxonomic activity, the entire biological community would soon end up in a state of confusion with regard to their own taxa of investigation and may have to knock the doors of scientists outside the country for seeking basic information on identity, nomenclature and even distribution of those taxa which occur at their door steps. While cautioning about such an ensuing serious problem I intend to outline here the paramount role of herbaria in allround development of botanical sciences including modern biology. This should also call for a dialogue between the classical biologists and experimentalists as to whether herbaria are redundant or they need to be maintained with added significance.

What is a herbarium?

Herbarium is a place where plants collected from far and wide are preserved in pressed and dried condition and are kept in pigeon holes of almirahs according to some accepted system. It is a great filing system for information about plants primarily in the form of actual specimens and secondarily in the form of recorded notes on labels attached on the sheets. In other words, herbarium is a vast reservoir of facts about plants.

Functions or utility

In order to wash out the wrong notion among a section of modern biologists it is necessary to highlight the diverse functions of a modern herbarium and prove how it acts as a connecting link between various disciplines. The following are a few important functions of a herbarium.

* Conservatory of material and data
* As a storehouse of collections including the valuable type specimens the herbaria greatly aid in all kinds of taxonomic researches
* Aids in teaching and in all biological researches
* Serves as a fundamental resource for identification of all plants of the globe
* Serves as source for collection of biodiversity information (to capture biodiversity information from herbaria is at least 10 times more cost efficient than to collect new data from field). Most estimates on global biodiversity today is based on herbarium collections only
* Aids in biodiversity monitoring; carrying out scrutiny of herbarium collections to obtain quantitative baseline data on the distribution and abundance of keystone species is essential for all monitoring programmes
* Aids in assessment of conservation status of a taxon (helps in cataloguing of rare and endangered species for conservation programme)
* Serves as a repository of historic collections and at times acts as the only record of past vegetation
* Serves as a source for search of new genetic material for improvement of our cultivated stock
* Aids in assessment and cataloguing of all species of economic potential; these may include commercial species, medicinal herbs, food plants and so on
* Serves as a source of material for investigations on anatomy, morphology, ecology, chemistry, molecular biology, pharmacognosy and for environmental impact assessments
* Seeds of herbarium specimens can be used to resurrect species extinct in the wild using modern technologies
* Herbarium, like a library, is a service institute; solves all queries about plants from scientists, administrators, lawyers, corporate personnel, industrialists, environmentalists and foresters
* Helps in development of computer databases on plants and maintains active links to international network of systematic resources and electronic knowledge base.

Thus, it is clear that herbaria contribute to the development of all biological disciplines. But today herbaria are completely ignored by the so-called modern biologists who have least knowledge of the significance of a herbarium. Although herbarium is a facility of a data bank on plants to be used by all biologists only a handful of surviving taxonomists are putting their efforts to nourish and maintain the fragile heritage of herbaria in the country. This has resulted in erroneous conclusion that herbaria are the establishments solely of taxonomists. Rather, herbaria are national facilities and their maintenance should be a national responsibility.

Some herbaria developed over several decades of efforts of taxonomists are today at the verge of collapse due to wrong impression among the ruling biologists that herbaria are merely a storehouse of collections of dead plants, which cannot contribute to the national development nor can generate funds for research forgetting that herbaria are simply a facility of a databank on plants from which all biologists draw their basic informations directly or indirectly about the plant species on which they carry out all advanced researches.

The significance of voucher specimens, on which varieties of researches are carried out, need not be elaborated here. It is only the herbaria which maintain such voucher specimens for posterity. Time and again the necessity of depositing the voucher specimens in some recognized herbaria has been stressed. But today this aspect is so much ignored that many modern biologists carry out outstanding researches on taxa but without maintaining voucher specimens nor do they feel the necessity. In the absence of voucher specimens vast amount of new data/new discoveries on a particular plant species quite likely may not pertain to the plant species studied. Even if the species is well known it may contain a number of ecotypes, cytotypes, varieties or strains and hence it is absolutely necessary to maintain the voucher specimens in any

herbarium to allow subsequent researchers to evaluate statements made in the literature about the characteristics of a given taxon. The editors of various scientific journals should also ensure that all authors cite the accession number/numbers of their voucher specimens and the herbaria where deposited. While this enhances the value of scientific findings, at the same time it strengthens the justification of the importance of the herbaria.

Thus, herbaria are helpful to both classical and experimental biologists not only for obtaining the basic data on plants but in also serving as a caretaker of the voucher specimens on which tremendous amount of literature accumulates. In view of this, are we unjustified in demanding for allocation of some percentage of funds from all research projects as service charge for development and maintenance of herbaria? It is also certainly unwise to score out the herbaria and taxonomic researches as establishments of no economic gains as the present trend goes.

National herbaria like the Central National Herbarium, Herbarium of the Forest Research Institute, Dehra Dun, and the Herbarium of the National Botanical Research Institute, Lucknow are critically endangered due to lack of sufficient trained manpower, facility and even due recognition by the so-called experimentalists. With the overgrowth of several modern disciplines the importance of herbaria has faded, resulting in such a damage that would be felt in the immediate coming years. Khoshoo[1] has rightly pointed out that taxonomists are a 'vanishing tribe' among the biologists and are greatly overshadowed by the so-called and more often second-rate biotechnologists and environmentalists.

Herbaria require large buildings and staff for curation of vast collections, laboratories for associated researches and funds for continuous explorations for enriching the herbaria, particularly in a developing country like India where the coverage of holdings is incomplete. The knowledge of variation within species is another aspect which is very limited. But the increasing financial squeeze and thoughtless prioritization of research programmes have greatly affected the overall health of the herbaria in the country. Often comments from scientists state that the massive collections in the herbaria be dispensed with and only few sample collections and type specimens be maintained[2]. There is therefore, an urgent need to educate the policy makers, the experimental biologists, and other key persons who matter much for development of herbaria in the country about the 'essentiality' of a herbarium.

A rational economic basis for maintenance and furtherance of herbarium research must consider the fact that botanists with all their concerted efforts have known only 1/10th of what exists in our tropical forests and still less is known of the economic utility of those species which are recorded. Infraspecific biodiversity and population variation of the rich tropical flora are little understood. But certainly maintaining and enriching a herbarium is expensive. A strict monitoring of the quality of the incoming collections and zones from where they come is essential in order to maintain the quality and not the size of the herbarium. More than one herbaria if any, within a city or town (e.g. Dehra Dun, Lucknow) can be considered for merging in view of the increasing cost of maintenance, manpower, space on buildings, etc., rather than 'killing' a herbarium due to wrong policies and apathy towards such classical subjects upon which many future solutions depend.

SCIENTIFIC CORRESPONDENCE

The academy fellowship problem

The problem

A science academy elects new fellows every year. In order to improve the overall quality of its fellowship, it decides to impose a new criterion that every new fellow elected shall be better than the median level of the existing population of fellows*. How fast will the quality of the fellowship improve?

*This criterion was proposed for the Indian Academy of Sciences by Professor V. Radhakrishnan in the mid-seventies.

A toy model

The above problem needs to be recast in a quantitative form. It is difficult to quantify 'quality' of a scientist but suppose in a toy model we use a variable x to measure it on a scale ranging from 0 to 1, with 1 being the mark of perfection. Let us measure the time in years with $t = 0$ denoting a starting year when this criterion is announced to be implemented in all subsequent years. Let $f_n(x)$ denote the cumulative quality distribution of fellowship in the year $t = n$, $n = 0, 1, 2, \ldots$ In the starting year the total number of fellows was N_0, say and suppose that by statutes, every year N fellows must be elected.

Denote by M_n the median of the distribution $f_n(x)$. Thus

$$f_n(M_n) = \frac{1}{2} f_n(1) = \frac{1}{2}(N_0 + nN), \qquad (1)$$

and while electing in year n, care is taken that all new additions shall have the quality parameter $x > M_{n-1}$. Improvement in quality will then be indicated by how the median M_n steadily increases in value year by year.

We still need to specify the quality distribution of the pool of scientists

from which the new fellows are chosen. We denote by $g(x)$ the cumulative probability that a scientist selected at random from this pool will not have the quality parameter exceeding x. Thus

$$g(0) = 0, \qquad g(1) = 1. \tag{2}$$

In this toy model we have ignored the reduction in the total population of fellows due to death or resignation (or even eviction).

With these specifications we can now pose the question more precisely: Given the functions $f_0(x)$ and $g(x)$, how does M_n increase with n?

Solution

First note that for $t = n$, the median criterion implies

$$f_n(x) = f_{n-1}(x) \text{ for } x < M_{n-1}. \tag{3}$$

For $x \geq M_{n-1}$, there will be addition of N fellows whose distribution will be assumed to be proportional to the function $g(x)$ over $M_{n-1} \leq x \leq 1$. Therefore, we have for $x \geq M_{n-1}$

$$f_n(x) = f_{n-1}(x) + N\,\frac{g(x) - g(M_{n-1})}{1 - g(M_{n-1})}. \tag{4}$$

Since for the distribution $f_n(x)$ there are $\frac{1}{2}(N_0 + nN)$ members with $x < M_n$, these comprise of the $\frac{1}{2}\{N_0 + (n-1)N\}$ members with $x < M_{n-1}$ together with the number $f_{n-1}(M_n) - f_{n-1}(M_{n-1})$ from the earlier distribution and the new addition as per (4) above. Carrying out this book-keeping we have

$$f_{n-1}(M_n) - f_{n-1}(M_{n-1}) + N\,\frac{g(M_n) - g(M_{n-1})}{1 - g(M_{n-1})} = \frac{1}{2}N. \tag{5}$$

Next we consider the number $f_{n-1}(M_n) - f_{n-1}(M_{n-1})$ which has arisen from steady addition to $f_0(M_n) - f_0(M_{n-1})$ over all the preceding years following the rule (4). Therefore,

$$f_{n-1}(M_n) - f_{n-1}(M_{n-1}) = N \sum_{r=1}^{n-1} \frac{g(M_n) - g(M_{n-1})}{1 - g(M_{r-1})} + f_0(M_n) - f_0(M_{n-1}). \tag{6}$$

From (5) and (6) we have the final relation

$$f_0(M_n) - f_0(M_{n-1}) + N\{g(M_n) - g(M_{n-1})\} \times \sum_{r=1}^{n} \frac{1}{1 - g(M_{r-1})} = \frac{1}{2}N. \tag{7}$$

This iterative relation determines the sequence $\{M_n\}$ in a step by step fashion starting with M_0, since for determining M_n we have all other quantities known from the preceding application of this relation.

A simple example

We will illustrate the above solution with a simple example in which both the initial distribution and the general population distribution are uniform with respect to the attribute x. In this case

$$f_0(x) = N_0 x, \qquad g(x) = x. \tag{8}$$

and the relation (7) gives

$$M_n = M_{n-1} + \frac{1}{2\sum_{r=1}^{n} \frac{1}{1 - M_{r-1}} + \frac{2N_0}{N}}. \tag{9}$$

Even with this simple example we cannot find a solution in closed form, but Figure 1 illustrates the march of M_n for $0 \leq n \leq 25$, $N_0 = 500$ and $N = 20$ obtained by numerical methods. The median value rises from 0.5 to 0.75 over twenty-five years.

The continuum version

The solution, however, becomes tractable even for the general case if we modify the problem by having a continuous input of fellows at all times instead of the discrete annual input. A simple analysis shows that the relation (7) is changed to an integro-differential equation

$$\left(\frac{dM}{dt}\right)^{-1} = \frac{2}{N}\left.\frac{\partial f(x,t)}{\partial x}\right|_{x=M(t),\,t_0} + 2\int_0^t \frac{g'(M(t_1))\,dt_1}{\{1 - g(M(t_1))\}}, \tag{10}$$

where the prime denotes derivative with respect to the argument. Here the rate of

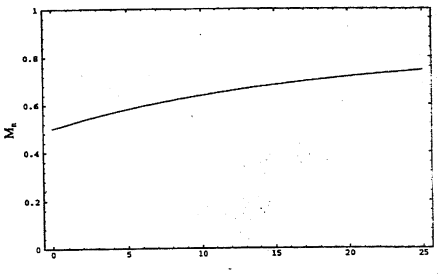

Figure 1. The figure shows how the median value of the fellowship quality improves with successive elections over 25 years in the simple toy model.

fellowship input is N, that is $N\delta t$ to be added in a time interval δt. Also, the fellowship distribution at time t is now denoted by $f(x, t)$ and its median by $M(t)$.

The equation (10) is solvable in closed form and in the general case we have

$$\frac{dt}{dM} = \frac{2}{\{1 - g(M)\}^2} \times \left[\int_{M(0)}^{M(t)} \alpha'(M)\{1 - g(M)\}^2\,dM + A\right], \tag{11}$$

$$\alpha(M) = \frac{1}{N}\left.\frac{\partial f(x,t)}{\partial t}\right|_{x=M,\,t=0}, \tag{12}$$

where A is a constant of integration. For the simple case of uniform distributions discussed earlier the solution is very simple:

$$M(t) = \frac{1}{2}\cdot\frac{1 + (2tN/N_0)}{1 + (tN/N_0)}, \tag{13}$$

and it fits the curve of Figure 1 very well. In fact an approximate discrete solution based on equation (13), viz.

$$M_n = 1 - \frac{1}{2}(1 + nN/N_0)^{-1} \tag{14}$$

satisfies the iterative relation (7) with a good approximation.

Supplementary comments on 'endemic, rare and threatened flowering plants of South India'

This note is to supplement Meher Homji's comments (*Curr. Sci.*, 1995, **68**, 1083–1084), on the article by Ranjit Daniels *et al.* (*Curr. Sci.*, 1995, **68**, 493–495).

Coining a term 'pseudoendemic' for a plant species like *Piper barberi* occurring in the southernmost parts of the W. Ghats in Kanyakumari District and also in a very closely adjacent and contiguous area in Kulathupuzha is rather misleading. Plants can be either 'endemic' or wide species. There is no 'pseudo' category in the plant or animal world. There are well-defined categories of endemics such as palaeoendemic, neoendemic, patroendemic, schizoendemic and apoendemic. It is better not to add new phraseology like 'pseudoendemic'.

As mentioned by Meher Homji, conjectural propositions on extinction phenomena based on insufficient data, that too from a small politico-geographical area, (Tamil Nadu!) are not appropriate. Biological extinction and man-made extinction must be conceived in their true perspectives. Biological extinctions involve the processes of 'way out' of species through millions of years of speciation and extinction in time space continuum. Unfortunately the current crisis of extinctions of biota is steered by anthropogenic intervention and habitat loss.

M. P. NAYAR

Tropical Botanic Garden and Research Institute,
Pacha-Palode P.O.,

R. J. Ranjit Daniels et al.'s reply:

We thank both V. M. Meher-Homji and M. P. Nayar for their interesting comments on our paper (*Curr. Sci.*, 1995, **68**, 493–495). In fact, the primary purpose of the paper was to invoke some discussion.

Regarding the issues raised by Meher-Homji (*Curr. Sci.*, 1995, **68**, 1083–1084) and that subsequently quoted by Nayar, we admit that Tamil Nadu is not 'south India'. However, we have just chosen to treat the plants of Tamil Nadu listed in the *Red Data Books* as a subset of those reported from the 'Madras Presidency' by Gamble. Madras Presidency, which included, at least in part, the four south Indian states, viz. Kerala, Tamil Nadu, Karnataka and Andhra Pradesh is in our opinion and geographically a fairly good representation of south India. We therefore feel that it is statistically appropriate to work with the available data on small subsets for drawing more general inferences.

On the issue of 'biological extinction and human-induced extinction', it is not clear to us how the distinction can be easily made. We are only highlighting the fact that certain species are 'more extinction-prone' than the others. We have also illustrated some of the possible reasons that make such species extinction-prone. Species on their natural 'way out' are as vulnerable to extinction as those which are being 'led' by humans. Whether we pay more importance to one at the expense of the other becomes more of a philosophical issue.

Finally, regarding the 'pseudoendemics' and the contention that there is nothing 'pseudo' in the natural world, we have an explanation as well. One has to admit the fact that all the status that we humans attribute to living organisms are 'relative' and at any stage be claimed as false. While it cannot be rationally argued as to why we should not use such terms as pseudo, it is easier to bring to the attention of the contender the fact that this term was not 'coined' by us. Although while writing this paper we thought we were introducing a new term to describe 'endemic' species, we discovered later that this term has been in use since 1990 after its first introduction by Nelson *et al.* (*Nature*, **345**, 714–716). The term was, as much as we have done, used to recognize 'endemic' species whose full range has not been sampled due to inadequate or uneven surveys.

A fast-growing cell line of *Taxus baccata* L. (Himalayan yew) as a potential source of taxol precursor

Taxol, a diterpene with exceptional anticancerous activity, is presently isolated from bark of Pacific yew, *Taxus brevifolia*[1]. It occurs as a very minor component in several species of *Taxus*[2]. Continued bark harvesting for taxol does not appear to be an adequate source to meet its demand[3]. There is a growing interest in alternative methods for taxol production such as from tissue culture of *Taxus* sp.[4–6]. The Himalayan yew, *T. baccata*, has been reported[7] to contain taxol and 10-deacetyl baccatin III, a precursor for synthesis of taxol. Here we report selection and cloning of fast-growing cell lines of Himalayan *T. baccata* for the production of taxanes.

Callus cultures were initiated from needle leaf of mature trees of *T. baccata* (Linn.) collected from Darjeeling area during July–October 1993. Callus was induced on explants on B_5 medium[8] supplemented with 2 mg/l 2,4-D, 0.1 mg/l kinetin and 0.1% casein hydrolysate, as reported for other species of *Taxus*[4,6]. Culture growth was main-

Figures 1 and 2. 1*a*, Early exponential phase cells of *T. baccata* suspension, *b*, visible colonies following plating after 21 days and *c*, variability in growth rates of cell colonies after 8 weeks of plating. **2.** Comparison of growth index of 25 established cell lines of *T. baccata*.

Table 1. Taxol and 10-deacetyl baccatin III content in four fast growing cell lines of Himalayan *T. baccata* after 6 months of culture

Kp 517	5.5	10 ± 1.5	33	177 ± 21	370
Kp 535	5.8	6 ± 0.5	15	160 ± 11	310
Kp 551	5.4	7 ± 1.2	Not detectable	168 ± 10	112

*Values represent mean ± standard error expressed on a dry matter basis.

tained on the same medium and was subcultured at 4-week intervals for six months. Suspension cultures were initiated by transferring callus tissues (2 g fresh wt) into 50 ml B_5 medium containing 2,4-D (0.2 mg/l) and kinetin (0.1 mg/l) in 250 ml Erlenmeyer flasks. The cultures were incubated on a rotary shaker (125 rpm) at 25 ± 2°C under continuous dark and were transferred every 15 days. Cell suspension cultures were maintained by inoculating aliquotes of filtered cultures (nylon mesh 0.5 mm pore size) equivalent to 10 mg dry wt (100°C/5 h) per ml of fresh medium containing 1 mg/l 2,4-D and 0.05 mg/l kinetin. Cultures were regularly passed through nylon sieve (0.5 mm) up to 6 months to obtain a fine cell suspension culture.

For selection of fast-growing cell lines, 3-week-old cell suspension cultures (GI 1.8 to 2.5) were centrifuged at 2000 rpm for 5 min, the liquid medium discarded and fresh medium added. Appropriate aliquotes were mixed in petri dishes with MS agar medium, held liquid at 40°C to give a final cell density of 5×10^4 cells/ml. The final agar concentration was 0.6%. The petri plates were incubated under continuous dark at 25 ± 2°C for 45 days. Cell division started within 7 days (Figure 1 *a*, *b*) and visible colonies (Figure 1 *c*) appeared on agar plates within 21 days of culture. Variability in cell growth rate was observed in different cell lines (Figure 1 *d*) initiated from the same explant. Growth index was calculated as (final wt – initial wt)/initial wt. Using this procedure, it was possible to select several cell lines showing faster growth. One major problem associated with *Taxus* cell suspension culture is the production of red coloured exudates (presumably phenolics) which effected cell growth. By following selection procedure as

described above, creamish-white cell suspension cultures could be established with minimum exudation of phenolics. These cell lines have been maintained for over 12 months in culture.

Taxanes in cell suspension cultures were measured using previously described methods[6]. For analysis of taxanes in cell suspensions and cultured media, cultures were harvested after 3 weeks of each passage, fresh weight of cell cultures recorded and the material lyophilized and extracted with chloroform (20 ml/g cells). The liquid medium was shaken with chloroform (100 ml/l). The chloroform extracts were evaporated to dryness, suspended in 5 ml methanol (HPLC grade) and filtered (0.2 μm) prior to HPLC analysis. HPLC analysis of taxol and 10-deacetyl baccatin III was performed in a Shimadzu liquid chromatograph (LC 10 AD) employing a reverse phase ODS–Supelcosil C-18 column (25 cm × 4.6 mm id), a Supelco guard column (Pelliguard™ LC-18 kit with 2 cm × 4.6 mm cartridge) and isocratic elution with acetonitrile:water:methanol (30:30:40). The flow rate was 1 ml/min and all chromatographs were plotted at 227 nm, using a UV detector (SPD 10A). A 0.25 mg/ml solution of standard samples of taxanes in MeOH was prepared and filtered through 0.2 μm filter prior to HPLC analysis. Identity of taxol and 10-deacetyl baccatin III was confirmed by retention time, spiking with standard and on the basis of spectral properties[9,10].

Extreme variability in cell growth rate was observed (Figure 2) in cell lines established by plating. Selection and recloning of faster-growing colonies led to establishment of four cell lines with rapid doubling time. Such variability in growth rates of cell lines has been reported in cell cultures of *T. brevifolia*[7,11].

Suspension cultures were established from the four cell lines (GI 5.5–6.8) and taxol and 10-deacetyl baccatin III were detected in cell suspension and culture media. However, taxol content was low and ranged from 0.003% to 0.007% in the four cell lines. The content of 10-deacetyl baccatin III varied from 0.162% to 0.212% (Table 1). Low levels of taxanes were also exuded in the liquid culture medium. The results are particularly significant since total chemical synthesis of taxol has not yet been achieved and an efficient semi-synthetic method starting from 10-deacetyl baccatin III has been reported[12]. Thus cell suspension culture of Himalayan *T. baccata* may be used as a source of precursor for synthesis of taxol.

Solar photovoltaic energy products: from semiconductor physics to advanced energy technology

Ashok Parthasarathi, D. Madhavan and V. K. Kaul

Physics to industry

There is a long road to be traversed between the original enunciation of a fundamental physical principle and the final realization of an application of that physical principle in the form of an industrial product useful to society. The bridging of this gap between physics and industry consists of a series of innovative steps ranging from perfecting laboratory scale processes to converting those processes and associated techniques through up-scaled, standardized production methods in a pilot plant, to large volume, cost-effective production on a commercially viable basis. This also includes the development of appropriate production equipment as needed. It is the collection of such knowledge, skills and equipment which constitutes the development of a complete technology package by which the physical principle is converted into an industrial technology to make a commercial product.

This paper presents such a case of 'Bridging the Gap' between semiconductor physics and the solar photovoltaic (SPV) industry. The case takes the form of the actual history of development and commercialization of SPV technology by our public sector company, Central Electronics Limited (CEL). CEL is today not only the nation's pioneer and largest manufacturer by far in the developing countries but the 5th largest manufacturer of single crystal silicon solar cells in the world.

Historical evolution of photovoltaics (PV)

The Photovoltaic (PV) Effect is the appearance of a voltage across a p–n junction or a rectifying contact as a result of its exposure to light. The light produces electron hole pairs. These pairs are separated by the inherent electric field across such junctions which causes a current to flow in the external circuit through the leads attached to the two sides of the junction.

Paper presented earlier in a more detailed form at the International Conference on Physics and Industrial Development: Bridging the Gap January 17–19, 1994.

Ashok Parthasarathi is in the Department of Scientific and Industrial Research, Ministry of Science & Technology, New Delhi, India. D. Madhavan and V. K. Kaul are at the Central Electronics Limited Sahibabad 201 010, India.

The Photovoltaic Effect was first discovered in an electrochemical cell by Becquerel[1] in 1839. The first solid state photovoltaic cell of selenium was made in 1877 by Adams and Day[2]. Although silicon solar cells based on natural (non-doped) junctions were made in 1941 (refs. 3, 4), it was only in 1954, that the first diffused p–n junction silicon solar cell was made by Pearson[5] and his group at Bell Telephone Laboratories, USA. It is that Pearson Cell which forms the basic building block of present-day solar photovoltaic energy generating systems.

SPV systems were first used commercially in 1957 as 'solar batteries' to power man-made earth satellites and this was the main application of solar cells till the mid–70's. However, it was the so-called 'oil crisis' of 1973 which spurred the development of technology for making solar cells, modules and complete SPV systems for *terrestrial applications*.

Solar PV systems are widely used to power various systems – both rural and industrial. Solar photovoltaic energy sources produce DC electricity directly from solar energy; they are modular in nature and their maintenance requirements are minimal; they are also absolutely non-polluting. Unlike other sources of electricity, the cost per unit of electrical energy generated does not depend drastically on the capacity of the photovoltaic energy generating unit installed. Therefore, small stand-alone SPV sources are just as viable economically as large and centralized ones, even at the present level of technology. All these advantages make solar photovoltaic energy sources eminently suitable for use in places where electricity is not available from conventional sources such as hydro, thermal or nuclear power generators and where diesel generators or electrochemical cells are not economical or feasible to use.

Single crystalline silicon technology is well understood and is mature due to its preponderant use in microelectronics. Hence, it is the principal raw material for making terrestrial solar cells as compared to other photoconductive semiconducting materials such as gallium arsenide.

The silicon PV chain

The silicon PV chain starting from the initial raw material polysilicon to the final SPV system is depicted in

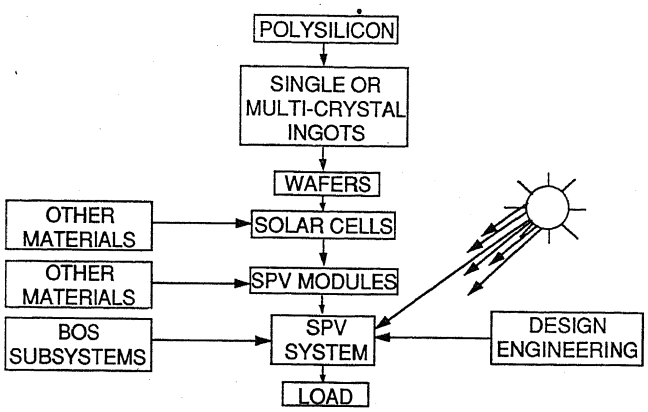

Figure 1. Schematic of silicon PV chain.

Figure 1. Polycrystalline silicon nuggets are the starting point in the PV chain. These are melted in a furnace and grown into single crystalline ingots. Such ingots are commercially grown by the standard Czochralski method upto a diameter of 100–150 mm. Then silicon wafers (thickness 200 to 400 microns) are sliced out of the ingots either by diamond impregnated internal diameter (ID) cutters or through multiple wire saws. The wafers are converted into solar cells through appropriate process technology using materials such as special chemicals, dopant elements e.g. phosphorus and boron and special conducting pastes of silver and aluminium compositions. These processes are drawn from the now well-known semiconductor device fabrication process, since the silicon solar cell is nothing but a large area semiconductor diode. A number of these cells are then interconnected and made into modules by means of basically a lamination process. This process involves the use (apart from the solar cells themselves) of other specialized materials such as tough tempered glass, soft polyester materials, metal frames and a junction box for extracting the electrical power. These SPV modules are the starting point for configuring a complete SPV system appropriate to a specific application. The final engineering of an SPV energy system is based on site and load-specific design including use of special computer software developed for that purpose. All the sub-systems other than the modules and the load (e.g. batteries, charge controllers/inverters) are termed the '*Balance of* the total Solar Photovoltaic *System*' (BOS).

The techno-economic performance of a solar cell or module is measured by its conversion efficiency (η). This is the percentage of the incident solar light energy which is converted by the cell/module into electrical energy. Today, n^+–p junction circular silicon solar cells of 100 mm diameter or square cross-section cells of 100 mm side have efficiencies in the range of 11%–14% in commercial volume production. The major factor presently preventing large-scale commercial exploitation of these power-generating devices is their high initial cost. Increase in the conversion efficiency has been recongnized as one of the key factors which would bring down the cost of photovoltaic power generation. To this end, researchers in laboratories and companies around the world are looking critically at the various loss mechanisms and attempting technological innovations to overcome the losses so as to approach the theoretical conversion efficiency limit of around 30% of n^+–p junction cells. In recent years, hand-made cells in the laboratory using hyperpure silicon wafers have shown efficiencies of 18%–19% for cells of 70 mm × 70 mm (45–50 cm^2)[6] and as high as 24% for small size cells (20 mm × 20 mm corresponding to 4 cm^2)[7]. The challenge is to achieve these higher efficiencies as *average* efficiencies of thousands of large area (100 mm × 100 mm) cells per day in commercial production in industrial plants and that too with commercial-grade CZ silicon wafers as the starting raw material.

SPV in India

Until 1975, activity in the field of SPV in India consisted only of R and D on solar cells in a few national laboratories. Development activity was directed only towards laboratory-scale solar cell fabrication, mainly oriented towards possible future space applications.

SPV in CEL

The activity at CEL in the area of solar photovoltaics extending over a decade and half, can be broadly broken up into the following macro-milestones:

1975–1980	:	R & D phase
1981–1985	:	Pilot plant operation
1986–1991	:	Industrial-scale technology proving and semi-commercial operations
1991 onwards	:	Commercial operation.

The development of solar cells for terrestrial applications was initiated at CEL following Government's decision, in 1975, to mount concerted efforts in this high-technology area. CEL has carried out extensive in-house R & D work spanning a decade for developing the complete technology for the manufacture of silicon solar cells and modules and designing, engineering and operating a pilot plant for production of such cells and modules based on the process technology and production engineering so developed. The activity also includes the development of a whole range of SPV systems and undertaking large-volume commercial production, supply, field installation and commissioning of such systems. Starting with processing of 38 mm diameter silicon wafers using vacuum metallization in 1978, CEL went through an evolu-

tionary development process in terms of both different sizes of cells and the whole range of process technology for making them. The milestones of development of solar cells and modules showing the evolution of the process and production technology at CEL is given in Table 1.

Solar cell process technology

The solar cell production process flow chart is shown in Figure 2. The process flow chart corresponds to the Screen Printed Technology (SPT) of making silicon solar cells, which is the dominant technology currently in use the world over and also the technology developed and in commercial use at CEL. A perspective of CEL's modern solar cell process area is shown in Figure 3. The individual process steps in the SPT are as follows:

Surface preparation

The raw silicon wafers sometimes have oil or grease on their surface, due to adhesion of the cutting coolant used at the time the wafers are sliced out of the silicon ingots. Therefore, it is essential to prepare the silicon surface properly for subsequent polishing and texturization by cleaning its surface with suitable non-ionic detergents.

Chemical polishing and texturization

The raw silicon wafers also have saw marks which are likely to affect the performance of the solar cells made from such wafers. So, these saw marks need to be removed. This is done by alkaline polishing of the wafers. Further, in order to absorb more incident light, the polished wafers are subjected to texturization by preferential etching with low concentration alkaline solutions.

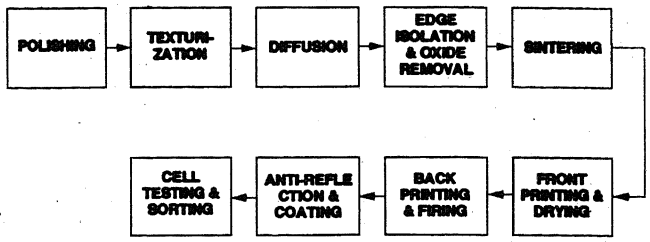

Figure 2. Solar cell process flow chart.

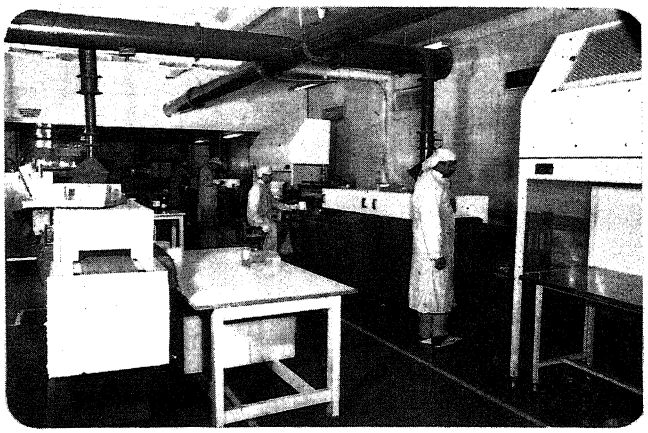

Figure 3. A perspective view of CEL's modern solar cell process area.

Figure 4. Indigenous automated chemical station.

All these chemical process steps are now being carried out using an indigenously designed and fabricated automated chemical station. The chemical station has been designed and fabricated in association with the Bhabha Atomic Research Centre (BARC), Bombay (see Figure 4).

Diffusion

This is the process step in which the n–p junction is formed on the silicon substrate. This process is carried

out using $POCl_3$ and N_2 and O_2 gases in a semi-automated diffusion furnace incorporating a microprocessor-based gas control and sequencing system.

Edge isolation

This process step is for the isolation of the junction at the periphery of the diffused silicon wafers. It is achieved either by chemical etching, plasma etching or laser scribing.

Back Surface Field

One of the limiting parameters of solar cell performance is the open circuit voltage which is limited due to the particular method of junction formation. This parameter (*i.e.* open circuit voltage) can be further enhanced by introducing another heavily doped p–type layer popularly known as back surface field. Screen-printed aluminium metallization is undertaken on the back of the wafer as the key step in this process. The introduction of the BSF enhances the overall efficiency of the solar cell.

Screen printing

For providing the contacts for carrier collection and interconnects both sides of the silicon, suitable conducting pastes are screen-printed and fired. This step is carried out by two semi-automatic integrated screen printers – one for screen printing the front surface of the cells and the second for printing the rear surface of the cells.

Anti Reflection Coating

To enhance the short circuit current of the solar cells, and hence their power output and efficiency, the reflection from the top surface should be reduced. This can be achieved by having a suitable Anti Reflection Coating (ARC) on the top surface. There are several techniques for applying such a thin ARC e.g. vacuum evaporation, plasma or spray pyrolysis. The most suitable technique for volume production is spray pyrolysis using suitable organo-metallic compounds.

Solar cell testing

The solar cells are then tested and sorted according to their current ranges, using a computer controlled automatic cell tester and sorter.

SPV module

Although solar cells are the basic building blocks of SPV power generating systems, it is the SPV modules

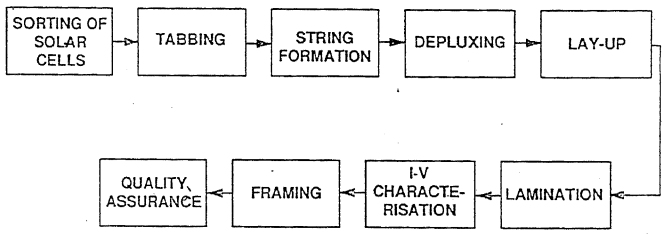

Figure 5. Moduling process flow chart.

and not the solar cell, with which system designers work. The current/power output of a single solar cell is too low to run most electrical appliances. So, several cells have to be interconnected to produce operationally useable power. In addition, the thin solar cells are fragile and so have to be protected from the environment. Thus a suitably interconnected combination of solar cells, when sealed hermetically with a transparent front glass cover, forms an SPV module. These modules can, in turn, again be suitably interconnected in series and/or parallel combinations and mounted on a metal frame structure to form an SPV panel. An aggregate of SPV panels in the field forms an SPV array. In respect of power levels, a typical standard module made of 36 nos. of 4" dia. circular cells will give a power output of 38–42 W whereas, a module made of 36 nos. of 4" pseudosquare cells will give around 45–50 W. The power and voltage levels of panels and array are dependent upon the specific system design and may, in practice, range from tens of watts to several hundred or thousands of watts of power and from a few volts to several hundreds of volts. Electricity generation from the SPV power source is totally modular in nature, and the SPV power capacity and system voltages can be tailored to meet the requirements of the user.

Module manufacturing process

The solar cell moduling process flow chart is shown in Figure 5. The individual process steps are as follows:

Lead attachment and stringing

Leads are attached to each solar cell by a soldering process. The lead attachment is done either manually or through a semi-automatic tabbing machine. After lead attachment, a definite number of cells are interconnected in series to form a string of solar cells in a defined pattern to give a sizeable output power. The stringing or cell interconnecting operation is also performed by a simple soldering process. Automatic/semi-automatic equipment are also available for performing these operations. An automatic tabbing machine in CEL's moduling line is shown in Figure 6.

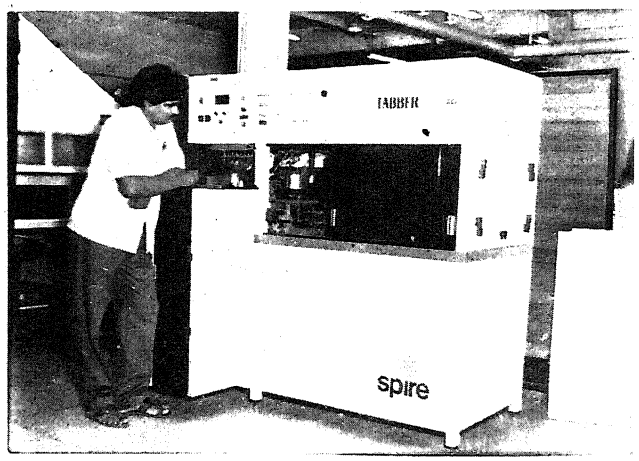

Figure 6. Tabbing machine for soldering leads to cells.

Lay up and encapsulation

The string of solar cells is then chemically cleaned and placed between a sheet of a special soft polymer called ethyl vinyl acetate (EVA) and a sheet of poly vinyl fluoride (PVF) which act as encapsulant substrate for the strings. A sheet of high transmission toughened glass is used as the substrate. The complete lay-up is then put in an encapsulating equipment called a laminator in which it is subjected to a specific time–temperature curing cycle to form the laminated module. While so far the lamination was being carried out using imported machines, indigenous laminators using state-of-the-art features including microprocessor control have now been got fabricated at a much lower price for carrying out this production step in CEL.

I. V. characterization

The laminated module is then tested in a sun simulator in which the module is exposed to a uniform illumination simulating the sun's insolation on a standard midday (i.e. normally designated as 'one sun' i.e. 100 mW/cm^2). Through electrodes attached to the module, the voltage across the module (V) and the current from it (I) are measured at different load conditions from 'open-circuit' (OC) condition to the 'short-circuit' (SC) condition and the complete I–V curve for each module is plotted automatically using a PC. Each such I–V curve is stored in the computer memory after suitably tagging it with the module number and other batch data. I–V characteristics of a typical module are shown in Figure 7.

Framing and termination

The encapsulated module is framed using aluminium channels of special design to protect the module from mechanical damage, and for mounting it on suitable

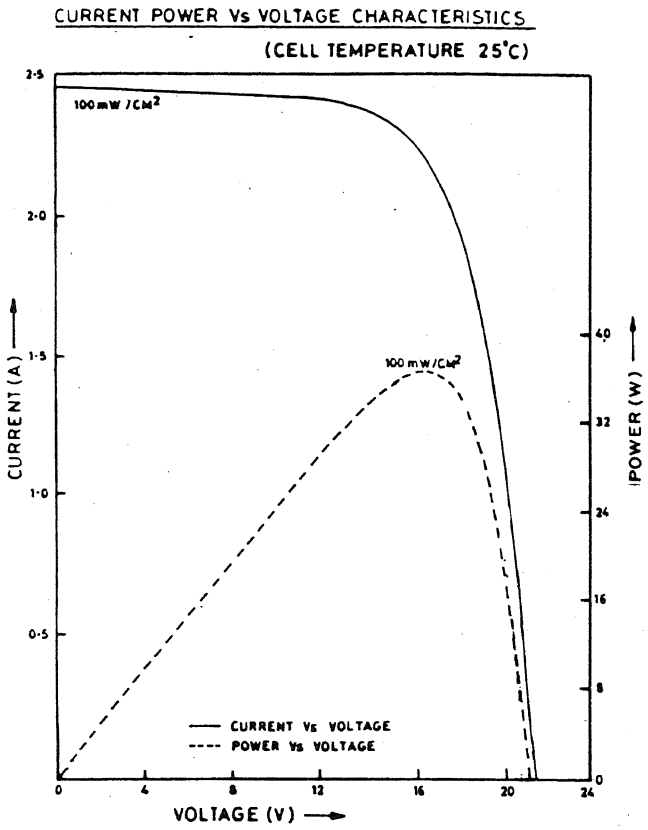

Figure 7. I–V characteristics of a typical module (36 No., 4" circular cells).

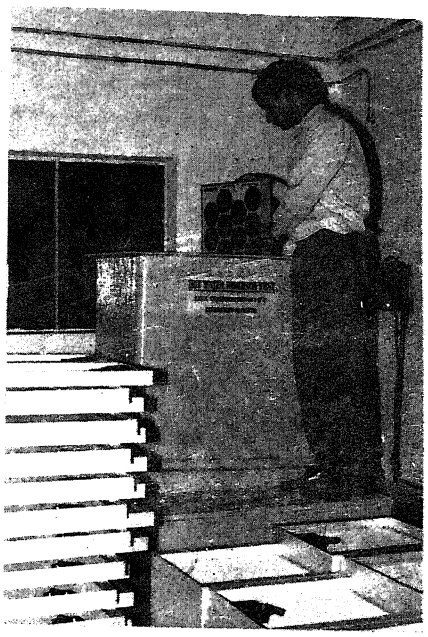

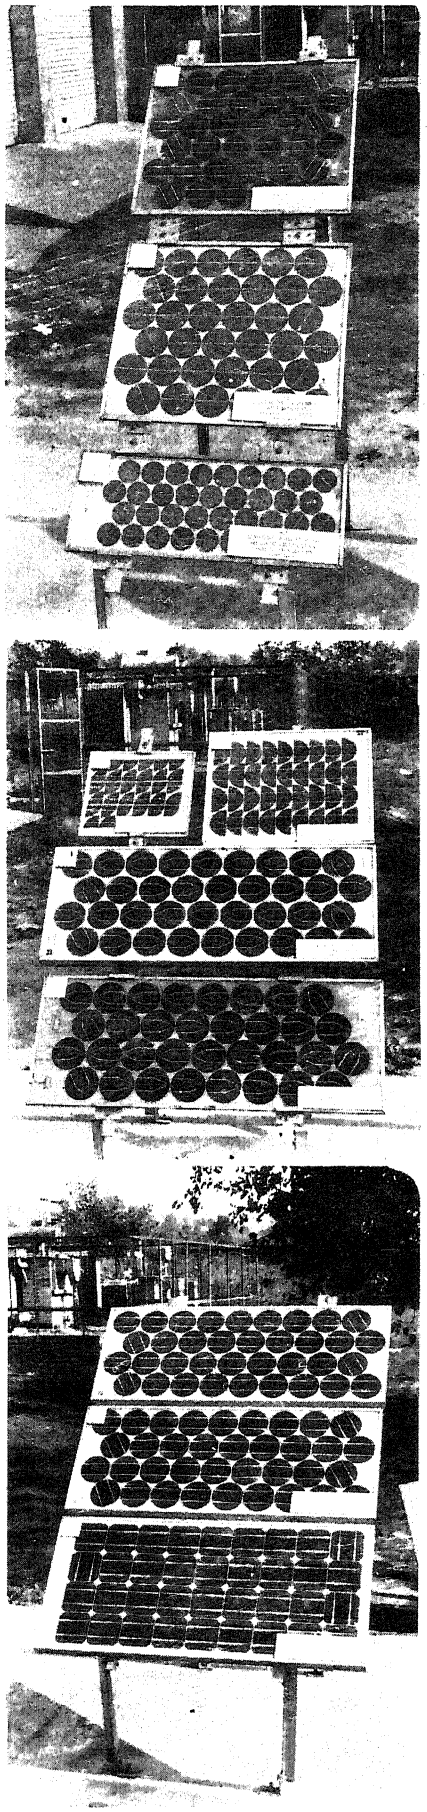

Figure 8. Hot water immersion test.

structures to form a panel. A nylon terminal box is then fixed to provide electrical terminals to extract electrical current from the module.

Quality assurance

A statistically selected number of modules from each production batch are then subjected to a number of quality assurance tests as also environmental tests such as hot water immersion test, hot/cold chamber tests, heat cycle tests, etc. Figure 8 shows the hot water immersion test equipment. The modules are now ready for use as a power generating source either individually or formed into a 'panel' or an 'array' depending upon the specific system design requirements.

The milestones of development of different types of modules keeping pace with the corresponding cell/module process technology milestones are given in Table 2.

Some of the typical modules from this product range are shown in Figures 9–11. The ONGC module is a pioneering instrinsically safe double glass module developed specifically for operation in explosion-prone environments such as on the off-shore, oil production platforms of the Oil and Natural Gas Commission (ONGC). These modules have also been certified to be intrinsically safe in Gr. I, Gr. IIA and Gr. IIB atmosphere hazardous area, by the Central Mining Research Station (CMRS), Dhanbad and accepted by the international insurers, Lloyds of UK. These are the first modules in the world with such certification.

As a result of all this technology development, CEL has presently the following types of modules in its regular production range:

	Type of module	Power output
a)	36 nos. of 4" circular cell module	38–42 W
b)	36 nos. of 4" pseudosquare cell module	45–50 W
c)	36 nos. of half circular cells of 4"dia.	10–14 W (8 V)
d)	36 nos. of half cells of 4" circular/ pseudosquare	10–20 W (16 V)
e)	Lantern modules – using 1/3, 1/2, 1/4 of 4" circular/pseudosquare cells	10 W (8 V/16 V)
f)	Lightweight foldable manpack module	24 W (16 V)
g)	Lightweight 'book case' type foldable module	14 W (14.5 V)
h)	Radio/tape-recorder module – 18 nos. of cut cells	3 W (8 V)

Solar photovoltaic (SPV) systems

The energy generated from the solar cell/module can be usefully harnessed to meet any specific load requirement through a properly configured SPV power system

consisting of the SPV modules/panels/arrays and other Balance of System (BoS) components such as battery bank, charge controller, inverter and loads such as pumps, lamps, vaccine refrigerators, TV sets, radio communication equipment, Very Low Power TV transmitters etc. A simple schematic of a typical SPV power system is shown in Figure 12. The SPV panel generates DC electricity from the sunlight incident on it. Where the SPV system is to operate during the daytime e.g. a solar water pump, the electricity generated by the panels can be directly used to run the DC pump. On the other hand, where the application is at night, such as powering a light, the electricity generated during daylight hours is stored in a battery through appropriate charge regulating electronic equipment (charge controller) and the power is drawn off the battery at night. The DC power generated can directly be used to run DC load devices. If the load is an AC device, the DC power generated by the panels (or from the battery bank) is converted into AC power of the desired phases (single or three-phase) and frequency (normally 50 Hz), through an inverter and used to power the load/equipment.

SPV systems development at CEL

The design of SPV systems are load and location-specific. SPV power systems are custom-designed for a

specific application at a particular geographical location, by taking into account both the intensity and diurnal/seasonal variation of solar insolation at that place. The total SPV panel/array capacity (in watts or kilowatts) and battery capacity (in ampere-hours) are accordingly chosen to meet the total load current, duration of daily use and the above mentioned solar insolation data. Automatic switching 'ON' and 'OFF' of the power from the SPV system to the load (say lights during night time) is also incorporated in the system design to restrict the usage of the SPV power to the exact duration of power requirement. This is to save the life of the system,

particularly of the batteries and electronic BoS. Development of appropriate SPV systems to meet different applications and user needs is a primary requirement for wider promotion of the market for SPV power systems. Therefore, parallel to the development of the process technology to manufacture cells and modules, CEL has put in a major effort of development-cum-manufacture-cum-installation and commissioning of a range of SPV energy systems. CEL has continuously been developing a variety of SPV application systems, subjecting them to extensive field testing and then obtaining user acceptance. Thereafter, these systems are produced and supplied against user demands. Indeed the systems constitute the total technology because it is through such systems that solar electricity is actually applied to meet social and economic needs.

CEL has developed a computer software package for designing site and load-specific, stand-alone, SPV systems. The software enables the drawing up of a complete system specification based on site information such as the lattitude and longitude, solar insolation and load parameters including the duration of daily usage as also provision of battery storage for a specified number of 'successive sunless days'. The system design then includes the selection of an appropriate module type (using circular cells or pseudosquare cells for e.g.) for use in the total SPV panels/arrays for the system. For this reason, a close interconnection may be perceived between the system milestones and the module product development milestones.

The milestones of such SPV systems development and introduction into the SPV market by CEL is given in Table 3.

System for ONGC platforms and TV transmitters of Doordarshan

The cases of the SPV systems designed and developed for the off-shore oil production platforms (Figure 13) of the Oil and Natural Gas Commission (ONGC) and for the Very Low Power TV Transmitters (VLPT) of Doordarshan (Figure 14) which are among the unique SPV systems supplied to customers as 'world-firsts' had more than one distinctive feature. The first of those features was CEL's close interaction with the users – ONGC (through Engineers India Limited) and Doordarshan – and with the equipment manufacturers Gujarat Communications and Electronics Ltd. (GCEL), Baroda and Electronics Corporation of India Ltd. (ECIL), Hyderabad for the UHF radio communication equipment and the telemetry equipment respectively for the ONGC Oil Platforms and the GCEL again for the VLPTs for Doordarshan, to match the SPV power system with the electronic equipment concerned. Secondly, through such interactions, the power consumption of the concerned

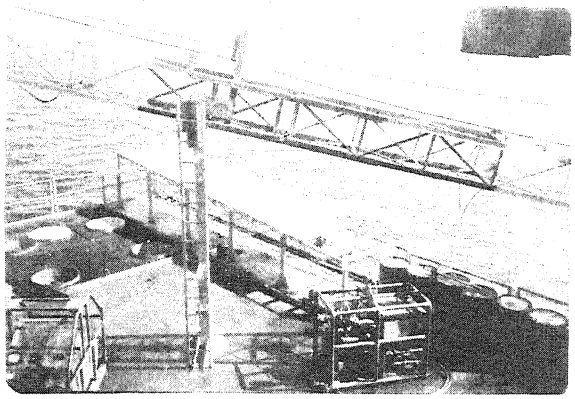

Figure 13. SPV panels on the off-shore oil well head platform of ONGC.

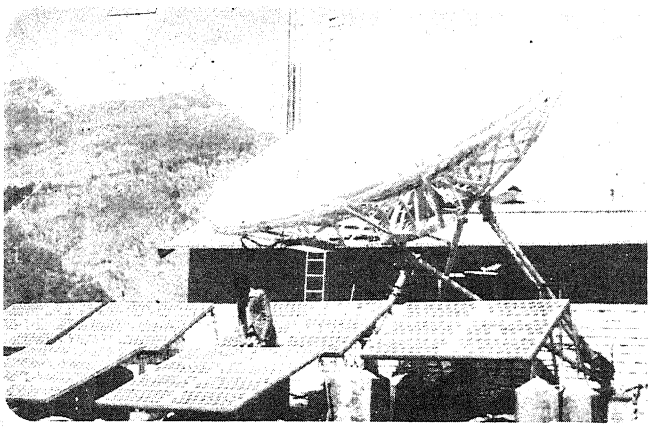

Figure 14. The panels of the SPV power source for the Very Low Power TV Transmitters (VLPT) of Doordarshan.

electronic equipment was reduced (in the case of the VLPT, to almost 50% of the original level) so as to make operation of the equipment with SPV power maximally cost-effective. More recently, a similar exercise is being done with the SPV lantern manufacturers so as to come out with an optimized least-cost product.

Categorization of SPV systems

SPV systems can be categorized on the basis of their application characteristics as rural, remote area and industrial systems. Such a categorized list of SPV systems developed and supplied by CEL is shown in Table 4.

A majority of the SPV systems meet the electricity needs for water pumping, village street and domestic lighting, vaccine refrigeration for immunization and other basic needs of rural areas not covered by conventional grid electricity. With the increasing use and

Applications by paramilitary forces

awareness of SPV power as an alternative source of energy, the battery manufacturers have come out with long life, maintenance-free batteries, specifically for use in SPV systems. This has rendered the SPV systems much more reliable and longer lasting for use in remote inaccessible areas.

SPV systems for the National Technology Missions

One of the major contributions of CEL's SPV power systems are to the National Technology Missions. Some 205 SPV-powered deep well water pumping systems using submersible pumps have been supplied for the drinking water mission through the Department of Rural Development. These pump systems are really complete village water supply systems and are capable of discharging 10,000 litres/day from depths as great as 120 m. Over 1,500 lighting systems using high luminosity Compact Fluorescent Lamps (CFL) have been supplied to as many Adult Education Centres in 14 states under the National Literacy Mission. Over 35,000 nos. of SPV power sources have been supplied for the Department of Telecommunication's Single Channel VHF Radio Links as part of the National Mission for Rural Communications. Solar-powered refrigerators are also being developed and supplied for the cold chain for storing vaccines and life-saving drugs in remote villages under the National Immunization Mission. Figure 15 shows CEL's SPV-operated lights in an Adult Education Centre at Salem District, T.N.

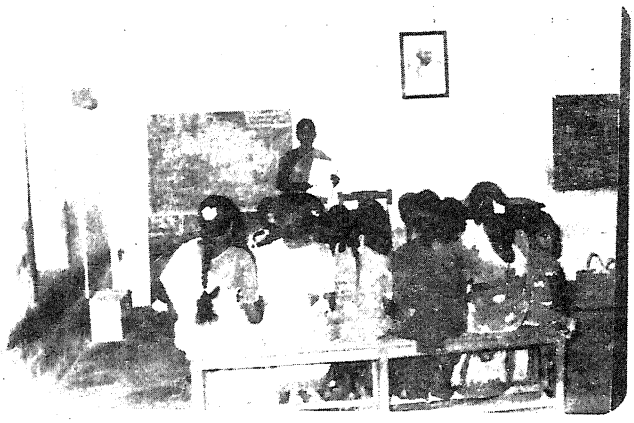

Figure 15. SPV operated lights in an Adult Education Centre at Salem District, Tamil Nadu.

Defence charger

The other pioneering development of CEL has been the 'Defence modules'. These are lightweight, foldable modules which can be carried 'manpack' by the soldier for charging the batteries of communication equipment (wireless radio sets) carried by him. These 'defence modules' have been type-approved by the Army, after exhaustive and extensive trials in actual field conditions ranging from the Rajasthan desert to the extreme cold weather conditions of the high Himalayas (3600–5500 m/12000–18000 ft.). Based on the feedback from such field trials by the customer, CEL has optimized the design, engineering and production technology of these modules. These foldable 'manpack' SPV battery charges have now been commercially manufactured and first supplies made to the Army. This defence-approved foldable module is the only one of its kind in the world. Figure 16 shows CEL's foldable modules in use at a base camp for charging batteries of communication equipment in the Indian Everest Expedition of 1984. The range and total number of SPV systems developed and supplied by CEL so far are shown in Table 5.

CEL has been responsible to a large extent for the creation of a national market for SPV products through its continuous and innovative development of new SPV application systems, even when no possible market for these systems existed.

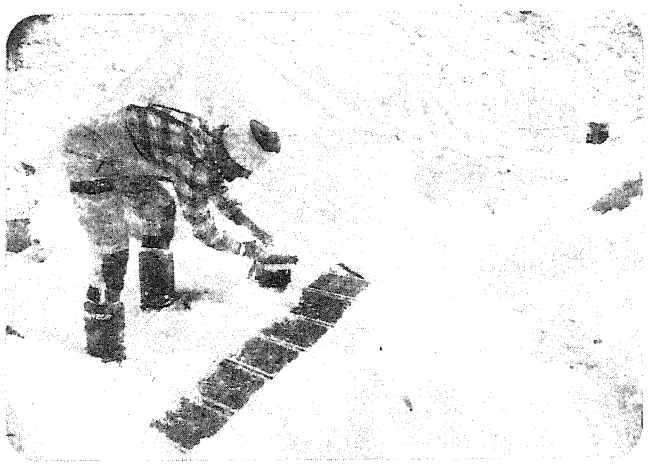

Figure 16. Foldable modules in use at a base camp for charging batteries of communication equipment in the Indian Everest Expedition of 1984.

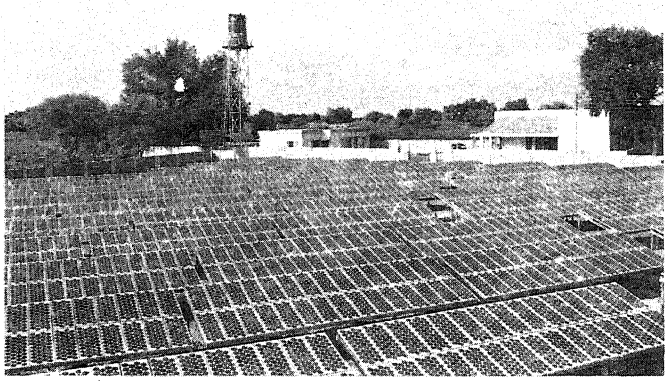

Figure 17. The SPV array of the 100 kW plant at village Kalyanpur, Aligarh District, UP.

With the development and technology and technology-proving phase behind it, the SPV market could now be truly said to have come of age both in our country and world over with ever-increasing use of solar photovoltaic systems and power plants coming into vogue. Such a growing market is expected to lead to further cost-reduction of SPV power as a result of both economies of scale and technological advances.

100 *kW power plants*

CEL has pioneered during 1992–94 the design, engineering, construction and operationalization of two 100 kW SPV power plants, Asia's largest such plants. The plants are located at villages Kalyanpur and Ghosi in the state of Uttar Pradesh. Figure 17 shows the SPV array of the power plant at Kalyanpur. These power plants have been fully designed by CEL and installed on a turnkey basis against contracts from the Non-Conventional Energy Development Agency (NEDA) of the Uttar Pradesh government. The power plant at Kalyanpur powers 450 domestic lights, 50 street lights and 15 nos. of 5 HP water pumps. CEL has set up the plant on a turnkey basis including supply of the special high voltage SPV modules, the lights, pumps, and the Power Conditioning Units (PCU), building the control room to house the PCUs and batteries, and laying the cables and interconnecting the whole system etc. The plant is designed on a modular basis so as to consist of 4 nos. of 25 kW power units including the corresponding SPV sub-array, PCU and batteries. The PCU contains a charge controller for safeguarding the battery life and an inverter for converting the DC electricity from the SPV array/batteries into 3-phase, 440 V, 50 Hz AC. The PCUs also have a phase synchronization unit to enable their interconnection in parallel to meet the total load requirement in the stand-alone mode. One 25 kW sub-system has been interfaced with the national AC grid through a 2.5 KMs, 11 kV feeder line. All the PCUs including the one for the grid interfacing have been totally designed indigenously to cater to the type of voltage and frequency variations prevalent in the Indian grid. Power conditioning units available in the international market do not have the capacity of handling such variations. The 25 kW basic unit has now become a

standard module for such plants to be installed by CEL in future. The modular concept ensures built-in redundancy in the power plant operation so as to meet the load requirement (atleast partially) in the event of failure of any particular PCU. The undertaking of these two SPV power plants, the 1st of their kind in the developing countries, has provided a wealth of real field experience to CEL in this area, thus adding to its already wide range of capability in the SPV power systems.

National Pump Programme

This year, a National Programme for large-scale distribution of SPV water pumps to villages throughout the country has also been launched by the Ministry of Non-Conventional Energy Sources (MNES). This programme has been conceived to give concrete shape to the announcement of the Prime Minister, P. V. Narasimha Rao, of large-scale use of solar photovoltaic (SPV) power for the benefit of populations in unelectrified villages. The programme envisages the sale of these SPV pumps directly to the users under a suitable leasing/soft loan mechanism with instalment payments spread over 10–20 years. This is being attempted to offset the disadvantage of the initial high cost of the solar photovoltaic systems which is acting as a prime deterrent for the large-scale deployment of these systems inspite of its many other advantages. The success of this programme will see the emergence of a very large market for the solar photovoltaic systems in India.

Thrust areas for R&D

In order to progressively increase the share of SPV in meeting global energy demands, intensive research and development work is needed on a continuous basis both to refine and bring down the cost of existing manufacturing methods and to bring into manufacture cells using novel technologies.

These and other measures taken on the technology front along with appropriate policy support from the Government, is expected to steeply reduce the cost of solar cells and modules and hence of the corresponding SPV systems in the country, by the year 2000.

Assessment of CEL's experience in 'Bridging the gap'

When one undertakes an 'Operation Hindsight' of CEL's experience with developing and commercializing SPV technology, several interesting features of 'bridging the gap' between physics and industry come to light.

First, in cell-making, cell-interconnecting and module-making, there is a close interplay between process steps and the equipment with which those steps are implemented in industrial production. Almost every production equipment has to be extensively 'tuned' or optimized in terms of parameter settings and operating conditions, in order to get the best results. Second, selection of an appropriate mix of manual operation and (semi) automation, the choice being made so as to minimize the overall process cost for a plant of 2–3 MW of cells per year. Third, in respect of the choice of the source of supply of the process equipment, a judicious mix of indigenous and imported equipment is made to achieve a cost-effective mix without trading off quality and yield. Some equipment are bought in the world market. This is done where technological sophistication and performance with high throughputs are the dominant consideration. In other cases, indigenous equipment are selected without sacrificing the same technical and throughput factors, but at far lower cost. Fourth, even where equipment are imported, modifications need to be effected in the equipment after use in the plant so as to optimize the equipment into the process line, thereby increasing its effectiveness and performance. Notable examples of such modifications done by CEL are in the tabber and laminator. Considerable modifications were effected in the machine while using it in CEL's line by which its performance increased several-fold. The knowledge acquired by CEL's engineers in making these improvements also provides a sound base for such equipment to be designed and manufactured in our country with substantial cost savings. Fifth, as the process is an integrated one, there is considerable interaction and interactive feedback between one production step and atleast the immediately preceding and succeeding steps in the total process sequence. Continuous iteration is therefore needed, *along the whole process sequence*, to achieve the highest performance solar cells. Sixth, and very crucially, continuous in-process measurements and off-line specialized measurements are needed for both process optimization and control and for product quality control and assurance. The science-base is ever-

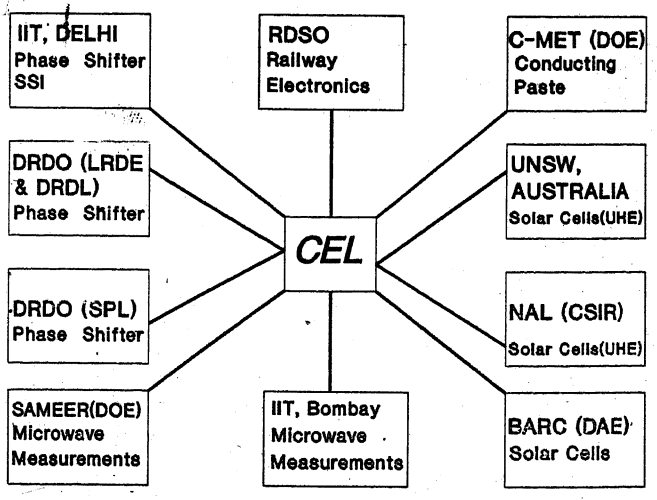

Figure 18. CEL's technology linkages.

present. Seventh, the whole process of technological advance is incremental and evolutionary in character i.e. relatively small improvements are being made all the time to improve process yield and product i.e. solar cell and module quality and performance. This has to be a continuous drive undertaken endlessly. Eighth, as the technology is continuously evolving in this way, the industrial work force operating the plant has to be extensively trained to do two things simultaneously: operate the plant on a disciplined basis with process and machine settings which have been specified as the 'optimum', at a particular point of time. However, to be open, at the same time to apply modified settings as the R & D effort (which is going on all the time) reveals the need for altered process parameters in order to achieve improved performance, whether of efficiency, yield or quality. This calls for flexibility of response and the collection, review of large amounts of data on a continuous basis.

External linkages

In the evolutionary development of technology described in the foregoing, the development process has been largely undertaken in-house by CEL's SPV group. However, there has also been close interaction and help from external agencies e.g. research laboratories, test houses and indigenous and foreign equipment manufacturers. This interaction is schematically shown in Figure 18.

Conclusion

The case of CEL's experience demonstrates the importance of entering an area of advanced technology at an early stage in the evolution of the technology and of the building up of indigenous capacity to convert science into technology and further, technology into industrial production capacity.

It also clearly brings forth the importance of pilot and demonstration phases in proving the new technology and the capability to optimally mix process know-how, equipment engineering and plant engineering.

As a result of sustained work over the last 15 years (1977–92), CEL has built up considerable capability in the SPV area of integrating science, technology and industry, rather than generating the scientific knowledge and then trying to bridge the gap to industrial application.

Mushrooms: Beauty, diversity, relevance

C. V. Subramanian

The literature on mushrooms is scattered, vast and rich. Current knowledge of mushrooms is essentially a synthesis of mushroom legends and myths, cults and folklore, re-inforced by mushroom biology and science. Mushrooms, indeed, are beautiful: beauty derives not merely from elegance and variety of form and colour, but structure and architecture superbly linked to function and life-style. Of ancient lineage, as decomposers, symbionts, and root-infecting pathogens, mushrooms have evolved with plant life through the ages. They are thus a unique component of the biota. Their diversity is a reflection of their lineage and their evolution. Mushrooms have merit, and meaning: species range from being delicious to edible to hallucinogenic to poisonous, even of potential value and use in medicine. Their enumeration, taxonomy, distribution, biology, chemistry, cultivation and conservation, naturally, are of great relevance and will remain of perennial interest and fascination for us.

THE theme of this paper reflects man's perennial fascination for mushrooms from times immemorial. Mushrooms are of ancient lineage, omnipresent, remarkably beautiful and diverse in their form, in their interaction with other biota and in all that they do. The suddenness and immensity of their presence in the wake of thunder and lightning, and their transience and fleetingness had been known since antiquity imparting a sense of mystery about the mushroom in man: amazed, he holds the thunderbolt, the thunder God responsible! Legend apart, the observation is in place. Impelled by curiosity, he notes that, of the many around him, some may be eaten and, with experience, he soon finds that some can be poisonous and so cannot be eaten. It seems plausible he also knew how to distinguish the edible from the poisonous, an exercise in taxonomy that calls for reliability, absolute reliability, ensuring safety. He does not stop there: the mushroom must be domesticated, like plants, must be grown, cultivated. Indeed, Dioscorides showed the way: the ancient method of sprinkling mushroom spores on to moist wood and waiting for the fruiting bodies to appear is apparently crude, but yet is the forerunner of modern methods of mushroom cultivation; it also marks the beginning of our insight into the biology of the mushroom. Experience with a diversity of mushrooms eventually leads to the recognition, in some, of inebriant qualities which, in time, we see, are built into religious practices or cults in many parts of the world. The use of mushrooms by primitive peoples is now well documented and the rise of the subdisciplines, ethnomycology and ethnopharmacology, and the corpus of data they present on the chemistry, metabolism, and biological activity of hallucinogens and other bioactive compounds is clear evidence of the remarkable intuition and ingenuity of primitive man in discovering the true properties of these mushrooms. Indeed, legend, myth and science all now become part of a totality that heightens the meaning and fascination of mushrooms for man.

One would imagine it was easy for early man to collect mushrooms in the wild to satisfy his needs. The practice of collecting mushrooms in the wild persists to this day in many parts of the world. Man's early concern with the natural occurrence of his favourite mushrooms, the habitats where they occur, the periodicity or the seasonal character of their fruiting, their abundance, and so on, indeed, marks the beginnings of mushroom sociology or ecology.

Mushroom biology

The occurrence of mushrooms on such familiar substrates as wood, litter and soil, implies a role for them in these microhabitats. Forest litter and forest soils are often literally permeated by fungal threads or tubes (collectively, the 'mycelium') often forming 'rhizomorphs', capable of free and extensive spread in litter and in soil. The distribution and development of 'mycelial cord systems' of decomposer mushrooms are often conspicuous in soil and in litter of deciduous woodlands. Many of these are what we may call true inhabitants of the soil though the routine soil dilution plate technique widely used by soil microbiologists to isolate fungi from soils may not reveal their presence in soil. These fungi may obtain food directly from the substrate which then serves as a food base for the mycelium of the fungus spreading radially therefrom.

C. V. Subramanian lives at 'Anjaneya', Plot 885, 62, Ramaswamy Salai, K. K. Nagar, Madras 600 078, India.

They have the enzyme systems required to break down substrates, especially lignin, hemicellulose and cellulose which are the main components of litter and of wood in the forest floor. In fact, degradation of lignin and wood is primarily a function of the great fungal group, the Basidiomycotina, to which all mushrooms belong, besides the pore fungi or polypores ('bracket fungi') and a host of others, more modest only in their general appearance and profile. Collectively, then, they are key scavengers of so much of the organic material in forest floors and soils, of agricultural and other wastes, all of which must be recycled for the sustenance of the biota. In short, the basidiomycetes are a key component in re-cycling of nutrients in many terrestrial ecosystems. Their biomass in forest soils and in forest litter is not easily quantified, but must be considerable. What is more, many mushroom species, and also other specific mycota, are symbionts of tree species, often obligately so, so that the symbionts in this remarkable partnership depend on each other for development and sustenance. That is a further indication of their relevance in forestry and afforestation programmes. Symbiosis leads to the development of mycorrhizas (literally, 'fungus roots') and there are innumerable such mycorrhizal associations ranging from the loosely specific to the not so specific. From the occurrence and characteristic distribution of their fruit bodies one might discern associations with particular tree species, reflecting a possible mycorrhizal relationship. Mycorrhizal fungi mostly are species of genera such as *Amanita, Boletus, Lactarius, Russula* and *Tricholoma*. The well-known fly-agaric, *Amanita muscaria* forms mycorrhizae with *Betula*, *Pinus* and possibly with *Carpinus*. Production of fruit bodies by mycorrhizas depends upon supplies of host-assimilates, and on host genotype, age of the host tree, soil type and soil amendments, and on weather and climate. The diversity of mycorrhizal fungi on a given tree species may increase with ageing of the tree species, so that there would be a succession of mycorrhizal associates on a given tree, a reflection of the low specificity of the mushrooms involved in such succession. Some mushroom species such as *Laccaria laccata*, and species of *Boletus* and *Tricholoma* present a dual behaviour, being mycorrhizal symbionts or being saprotrophs capable of decomposing leaf litter.

There is a succession also on dying and dead wood and other substrates. Some species in some genera preferentially colonize specific substrates: many wood-rotters belong to the group, the Aphyllophorales. Those involved in the decomposition of leaf litter and non-woody litter largely belong to the genera *Collybia*, *Clitocybe*, *Marasmius* and *Mycena*.

The mycelium of some species in litter and wood shows bioluminiscence. In fact, the fruit bodies also are luminiscent in some species, e.g. jack-o-lantern (*Clitocybe illudens*), the poisonous moonlight mushroom (*Lamptero-myces japonicus*). In the case of *Mycena rorida* v. *lamprospora* the spores are luminous.

There are also mushroom species such as *Armillaria mellea* that infect living trees, especially root systems, and cause root disease. Root infection may also be due to polypores such as *Fomes annosus*. When the tree has been weakened, colonization by other mushroom species or by polypores and other basidiomycetes may follow. The mushroom group, the Marasmieae, especially the Marasmiineae, comprising species of genera such as *Mycena*, *Crinipellis*, etc. are common on tropical wood and litter, but some are pathogens. *Crinipellis perniciosa* is pernicious, being parasitic on cocoa trees (*Theobroma cacao*) and on *T. bicolor* and the wild species, *T. speciosum*: the fruit bodies are formed only on witches broom deformations of the diseased host. Originally known only in S. America, the disease now occurs wherever cocoa is grown, from Ecuador to the West Indies. *Crinipellis perniciosa* is unique in having a distinct parasitic and a saprophytic phase. The parasitic mycelium in the tissues of the brooms is intercellular without clamp connections; the saprotrophic mycelium arises from the parasitic, following death of broom tissues and has clamp connections: it can then be isolated and grown on media. *Marasmius viegasii* causes a root rot of coffee in Brazil: rhizomorphs on roots of affected trees are conspicuous. Curiously, some mushroom species that are parasitic on trees such as, for example, *Armillaria mellea*, are also symbionts of large achlorophyllous orchids. Some achlorophyllous 'saprophytic' angiosperms, including the Orchidaceae, obtain their carbon compounds through fungi that are parasitic or mycorrhizal on green plants.

The life of the mushroom

The life of the mushroom from the germination of the spore through development of a hyphal system to the production of the characteristic fruit body is a continuum punctuated by events of import. First, nutrients and water are transported from the vegetative mycelium which draws its nutrition from the substrate or from a host. The elongation of the stipe is a result of divisions as well as elongation of individual cells. The fruit body itself is short-lived, and is organized for the production and dissemination of spores. The variations in colour, consistency, configuration, construction and dimensions of the fruit body, and the range in shape, colour and size of spores and other features all contribute to the diversity of mushrooms we see around us. The fruit body size of the most common mushrooms falls within a normal range, but some may be unusually small and others unusually large. The largest fruit body of a mushroom is perhaps that of *Boletus colossus* from the Malagasi Republic: it has a stipe 30 cm tall and 22 cm thick, and a pileus 60 cm wide and 4–6 cm thick, and weighs about 6 kg. Some bracket-fungi are many times larger and weigh much more.

Highly synchronized basidia are typical of the agarics and the polypores; in the latter the hymenium is protected

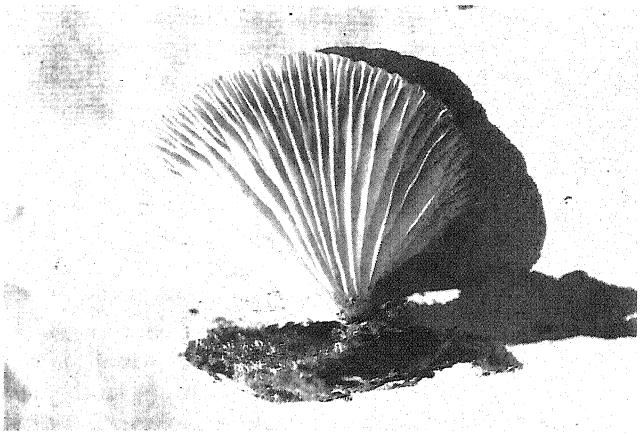

Figure 3. *Pleurotus cystidiosus. Pleurotus* spp. are edible and are cultivated. Note gill architecture.

Figure 2. Polypore on wood. Polypores are great decomposers of wood and play a major role in recycling of nutrients in the forest floor.

Figure 4. *Auricularia polytricha*, the Chinese wood-ear (*mu erh*) fungus. Edible, cultivated. Hong Kong is the principal exporter of this species.

by elaborate trimitic fruit bodies adapted to spore discharge under adverse conditions; in the former well-organized hymenia are formed on relatively fragile fruit bodies that can expand rapidly to discharge the spores during favourable environmental time-frames. The jelly-fungi (Tremellales) are unique in having relatively primitive hymenia, and in their ability to remain viable through time-frames of repeated wetting and drying.

There have been many penetrating studies of the development of the fruit body itself and its morphogenesis, the relevance of which must be obvious to anyone interested in the induction of fruit bodies and increasing their production at will experimentally. Once dikaryotization is accomplished, the dikaryotic mycelium is virtually perennial and persistent and often long-lived, and can produce fruit bodies year after year, season after season. Radial spread and fruiting often produce 'fairy rings', especially noticeable in the case of *Marasmius oreades* and *Chlorophyllum molybdites*. Normally, dikaryotization is a pre-requisite for fruiting, but monokaryotic mycelia may produce fruit bodies under special conditions. Morphogenesis begins with initiation and, following a pause, is consummated by sudden and rapid growth, expansion and maturation. The fruit body appears all on a sudden, and vanishes quickly too. Size and form of fruit body are closely related: smaller fruit bodies usually have slender stipes and larger ones stout stipes. The stipe serves to hold the pileus in position for release and dissemination of spores; it is held erect due to the turgor pressure of its cells. The positive role the pileus plays in the elongation

Figure 5. *Termitomyces heimii.* Tropical, associated with termite nests. Edible; collected in the wild and eaten.

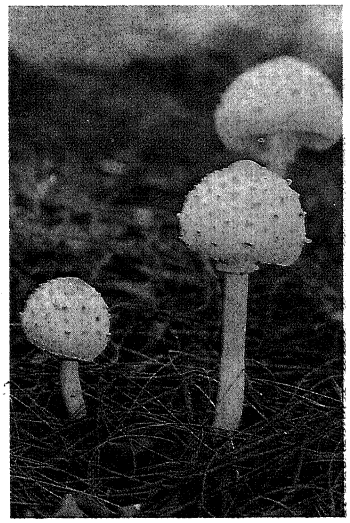

Figure 7. *Chlorophyllum molybdites.* Poisonous. Often forms fairy rings in lawns.

Figure 6. *Termitomyces.* Associated with termite nests in the tropics. The stipe arises from subterranean termite nest. Edible.

Figure 8. *Gymnopillus spectabilis.*

of the stipe first postulated by Schmitz in 1842, is now recognized and has been demonstrated experimentally, for example, in *Agaricus bisporus*, *Coprinus radiatus* and *Flammulina velutipes*: growth control resides in the pileus, specifically in the lamellae.

The way in which the fruit body as a whole, and the configuration and arrangement of the gills and the basidia in the pileus, are functionally adapted to life in a habitat is remarkable. There is a regularity in gill development and gill spacing. The architecture is such that a basidiospore discharged violently falls freely without striking the adjacent gill.

How is this accomplished? As described by the great Buller, to whom we owe much of our knowledge of the biology of the mushroom, the spore trajectory is a spo-

rabola: the horizontal flight is completed in a fraction of a second and is followed by a vertical fall that is gravitational and slow. The system of gills is such that, while they converge from the circumference of the pileus towards the stipe, they all cannot be of the same length as that would make them far apart towards the periphery, if they are satisfactorily apart near the stipe. The solution to this situation is seen in the insertion of shorter gills between longer ones. A spore fall rate of the order of about half-a-million a minute is common for a normal-sized mushroom. Naturally, a spore cloud is the result. By removing the cap from the stipe and placing the cap naturally oriented on, say a sheet of glass, one can have a

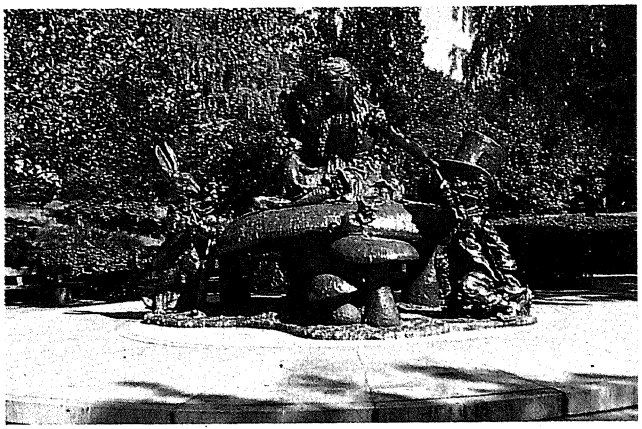

Figure 9. The Monument to Lewis Carrol in Central Park, New York. The sequelae to nibbling the mushroom by Alice, described by Lewis, are well known. Lewis got the idea from the reference to hallucinogenic mushrooms in M. C. Cooke's text-book on fungi.

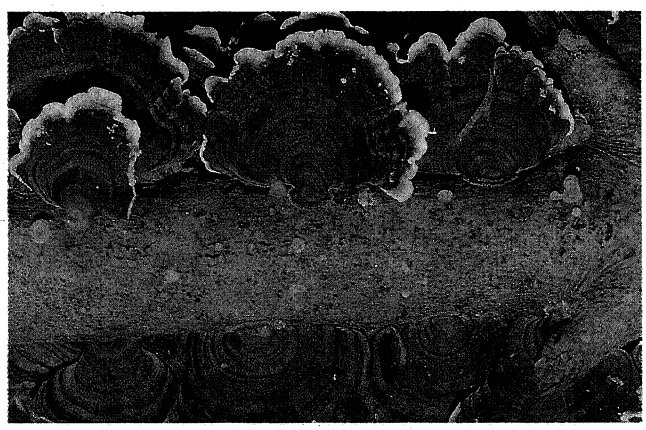

Figure 10. *Coriolus versicolor* is highly valued in Chinese medicine. Causes white rot in wood; sometimes a weak parasite, it forms mycorrhizas with *Galeola foliata*, an achlorophyllous liane.

spore print on the glass in a matter of a few hours. The colour of spores is diagnostic.

Edible mushrooms: Occurrence, diversity

That many mushrooms are edible, and some are delicious, has been known, from ancient times. There are Roman mosaics depicting mushrooms. There is a range or diversity of mushrooms in the wild that are edible and, in countries where they are popular, where there are mycophiles, for example, in eastern Europe, collecting in the wild is common. The common wild species include *Can-*

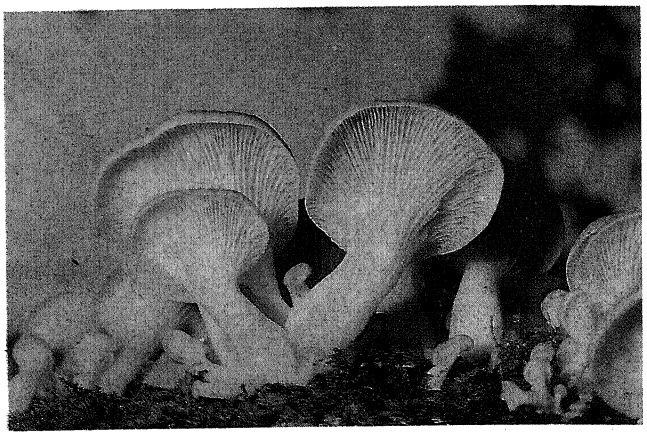

Figure 11. *Pleurotus ostreatus.* Edible, cultivated.

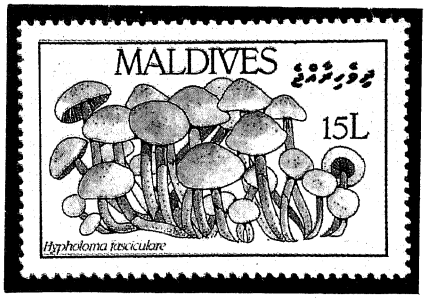

Figure 12. *Ganoderma lucidum* (ling-chi in Chinese, *linjue* in Thai; also known as the Reishi mushroom). Cultivated extensively in China, Japan, Korea, Thailand. The World Reishi Mushroom Institute in New York and the Arunyik Mushroom Centre in Thailand are engaged in standardizing the quality of the mushroom and its medicinal properties and use.

therellus cinnabarinus (Chanterells), *C. cibarius*, the boletes, *Boletus edulis*, *Suillus luteus*, *S. granulatus*, *Leccinium aurantiacum*, *L. testaceoscabrum* • and the Amanitas such as *A. caesarea*. Many of these are not easily cultivated since they are mycorrhizal and fruit bodies are normally produced only in mycorrhizal association. It is then quite reasonable to speculate on the possibility of having, in afforestation programmes, tree species with mycorrhizal associates from among mushroom species that are edible. The introduction into France and Central Europe of the White Pine (*Pinus strobus*) from the United States in the middle of the last century is an example. The new French pine woods showed an abundance of fruit bodies of the delicious *Suillus placidus*: one cannot be certain if the fungus came with the pine from the US or

Mushrooms on postage stamps

was already present in French soil and now had the host of its choice to colonize. The introduction of the white pine, a blessing in this way, was otherwise, for quite another reason: its high susceptibility to white pine blister rust. However, one can cite other examples of tree introductions with a high measure of success in providing the tree with an effective or suitable symbiont and, in the process, establishing a mycorrhizal relationship productive of a crop of fruit bodies of a prized mushroom. Success in such a venture implies judicious choice of a mushroom that is edible, and knowledge of its taxonomy and biology, especially its behaviour in symbiosis and in fruiting. The diversity from which a choice can be made includes many species such as *Tricholoma matsutakae*, *Amanita caesarea*, *Suillus granulatus*, *Boletus edulis*, *Leccinium aurantiacum*, *Lactarius deliciosus*, *Cantharellus cibarius* and *C. cinnabarinus*.

There are also many mushrooms that are primarily saprophytic and so can be grown in culture and cultivated to yield fruit bodies that can then be harvested. The button mushroom, *Agaricus bisporus* is the most popular, accounting for slightly over one half of the total of world mushroom production. 'Speciality mushrooms' such as *Shiitake* (*Lentinus edodes*), paddy straw mushroom (*Volvariella volvacea*), oyster mushroom (*Pleurotus*, especially *P. ostreatus*: also *P. eryngii*, *P. floridanus*, *P. sojor-caju*, *P. cystidiosus*) and enokitake (*Flammulina velutipes*) are becoming increasingly popular. Shiitake which is the mushroom of choice in Japan, Korea and China, has a long tradition of cultivation: it is cultivated on wood, virtually on logs of wood cut from hardwood trees such as oak, chestnut, etc. – species of *Quercus*, *Castanea*, *Carpinus*, *Alnus*, *Acer*. *Shiia* stands for *Pasania* and the name Shiitake stems from the fact of its frequent occurrence on shiia and the fact that it can be cultivated on shiia wood. Shiitake occurs naturally as a saprophyte on wood of deciduous trees such as oak, chestnut and beech and on shiia in eastern Asia from China and Japan to Vietnam and Cambodia. *Volvariella* and *Flammulina* are sold fresh. The button mushroom and shiitake are sold both in the fresh and the dried forms.

Auricularia polytricha, the ear fungus, and *A. fusco-succinea* – not strictly mushrooms, but both basidiomycetes – are quite popular in many parts of southeast Asia (China, Japan, Thailand, Taiwan and some islands in the Pacific): they are cultivated on logs of wood or sawdust. There are also several species, not yet intensively cultivated but with potential such as *Grifola frondosa*, *Hypsizigus marmoreus*, *Hericium erinaceum*, *Oudemansiella mucida*, and several species of *Termitomyces*. *Termitomyces*, as the very name suggests, is associated with termite nests in the tropics and is collected in the wild and eaten.

The nutritive value of some of the quality mushrooms very nearly equals that of milk. Mushrooms contain high levels of amino acids such as lysine and leucine, carbohydrates, vitamins, and unsaturated fatty acids, with a mineral content exceeding that in fish and meat, and twice that in most vegetables.

Recent studies culminating in the discovery of thermostable components, cytotoxic substances, and antibiotics in mushrooms (see Subramanian, *Curr. Sci.*, 1991, **60**, 290 for Steglich's report of antibiotics in mushrooms) reinforces the need for caution in using raw mushrooms in the dietary, in salads, for example. The occurrence of toxic metabolites such as the thermolabile audiotoxic *volvatoxin* in the paddy straw mushroom and *flammutoxin* in enokitake call for a reassessment of the wisdom of their use as food. Hydrocyanic acid is produced in quantity by some species (e.g. *Marasmius oreades*, the fairy fungus), but from its volatility little of it would remain after cooking.

The genus *Agaricus* to which the common edible button mushroom (*A. bisporus*) belongs, comprises two groups of species, viz. (a) those turning somewhat yellow on bruising (Flavescentes) and (b) those staining red (Rubescentes). The yellow staining species such as the edible *A. arvensis* and *A. bisporus* are known to accumulate considerable amounts of the heavy metals, cadmium and mercury. Other heavy metals known to accumulate in mushrooms include lead, caesium, iron, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, strontium, thallium, uranium and zinc. Accumulation of cadmium and selenium and other heavy metals in shiitake would render it unsafe for human consumption.

The occurrence of the hydrazine derivative *agaritine*, and the diazonium derivative from it, in *Agaricus*, and the fact that the *p*-hydroxymethyl-phenyldiazonium ion and decomposition products of agaritine can be carcinogenic pinpoint the need for caution in the use of these mushrooms. The agaritine content of fresh and processed cultivated mushroom has been studied: the average agaritine content is around 0.088% based on fresh weight. We certainly need more data on the agaritine content in mushroom species and their possible biological effects.

The corpus of data on methods of cultivation, strain improvement, and biotechnology of mushroom production is enormous and cannot even be touched on here.

Poisonous mushrooms: Syndromes, toxins

Poisoning from eating mushrooms has been known since antiquity. As one would expect, there is a variety of syndromes, and a variety of mushrooms involved.

The most deadly and the most notorious is the Death Cap, *Amanita phalloides*, presumably also the mushroom ingeniously used by Agrippina to do away with her husband, the Roman emperor, Claudius Caesar, in her bid to ensure succession to the throne by her son, Nero – ingenious in the sense that the essential properties of *A. phalloides* had been known to the Romans in advance of chemical studies of the toxins which came centuries later. Claudius, in fact, was poisoned with a dish of a mixture of

the edible *A. caesarea* (so named because Caesar was very fond of this mushroom!) and the deadly *A. phalloides* so that the poisoning itself went unsuspected. The Romans, then, knew the incubation period required by the poison to act, as arousal of suspicion had necessarily to be avoided in administering the poison to the Emperor. Knowledge, then, of the poisonous nature of mushrooms and of the precise symptoms of poisoning naturally preceded critical chemical data on the toxins and the *modus operandi* of the toxins. As far back as 1759, the great German naturalist Jacob Christian Schaeffer (of Regensburg: see Subramanian, *Curr. Sci.*, 1991, **66**, 289) underlined the need for chemical studies of the fungi. In Germany, fungal chemistry flourished under the leadership of Zopf, Zellner and Kogl. And more recently, knowledge of the chemistry of the metabolites and toxins of poisonous mushrooms has been strengthened by the work of several scientists, notably Wieland and Faulstich.

The most potent toxic substances in mushrooms are the cyclic tryptophan-containing oligopeptides that characteristically occur in species of the genus *Amanita*. The genus *Amanita* is unique in having species that are edible, some that are poisonous, and some that are hallucinogenic. The 'Phalloides syndrome' refers to poisoning by *A. phalloides*: it is characterized by a latent period of about 10 h (so that the victim remains unaware of the poisoning and, by the time he becomes aware, it may be too late to seek a remedy!) and a two-phase sequel in which gastrointestinal disturbances (severe abdominal pain and colic, nausea, diarrhoea, vomiting) are followed by progressive liver dysfunction. Accelerated pulse, dehydration, cramps in the legs, and a lowering of blood pressure may accompany the primary symptoms. Two groups of bicyclic peptide toxins have been identified: (a) the *amatoxins* that are octapeptides with an indole (R)-sulphoxide bridge, and (b) the *phallotoxins*, that are heptapeptides with an indole-thio-ether bridge. Nine amatoxins and seven phallotoxins have so far been identified. Compared to the amatoxins, the toxicity of phallotoxins to liver cells is quite low. It is now generally agreed that phallotoxins are not involved in the syndrome; on the other hand, most of the effects are ascribed to amatoxins. The damage to the liver is primarily on nuclei of liver cells, specifically, inhibition of RNA-polymerase B. Amatoxins are known to inhibit RNA-polymerase B in all eucaryotes except amatoxin-accumulating fungi and a few *Drosophila* species, some of which inhabit these fungi. Because of their specific inhibition of RNA polymerase B, amatoxins have become an important tool in biochemical studies. About 5–7 mg of amatoxin would be a lethal dose, depending on the body weight of the victim. Ingestion of the equivalent of 50 g of fresh weight of the fungus or a single fruit body, then, can be fatal.

Amatoxins occur in *Amanita verna* and *A. virosa*, besides *A. phalloides*, all of which are myeorrhizal. Amatoxins are also known to occur in several species of the genus *Galerina* which are deadly poisonous: *G. marginata*, *G. autumnaris*, *G. badipes*, *G. beinrothii*, *G. unicolor*, *G. venenata* and *G. sulciceps*. *G. marginata* is common on deciduous wood, particularly on conifers. *G. sulciceps* is tropical and fatal cases of poisoning from this fungus were reported from Java in Indonesia many years ago. Poisoning from species of *Lepiota* several of which contain amatoxins and are deadly poisonous (e.g. *L. helveola*) represents another example of the Phalloides syndrome.

Protein conjugates of amatoxins are ten times as toxic as natural amanitins and yet, the fact that these can be used for raising amatoxin-specific antibodies would now facilitate use of polyclonal antibodies for amanitin immunoassays. A monoclonal antibody, then, could be a potential antidote in the immunotherapy of human poisoning by the deadly Amanitas.

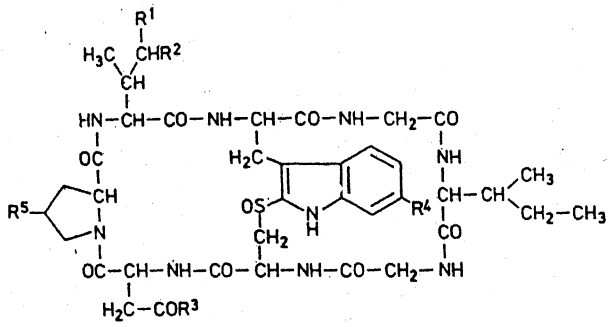
A syndrome with a long latent period and a two-phase course similar to the Phalloides syndrome is often due, not to *Amanita*, nor even a true mushroom, but a species of a fungus belonging to the Ascomycotina. *Gyromitra esculenta* has long been considered edible, as the specific epithet itself suggests. But there have been many cases of poisoning in some parts of Europe: the demonstration of the occurrence of a toxic substance, *gyromitrin* with high toxicity to the liver, confirms that the species is poisonous. On the other hand, gyromitrin is not stable, and most poisonings are apparently from eating of raw or insufficiently cooked fungus. In pure culture, even the mycelium has been shown to have the toxin. It is also likely that there are strains of the fungus that are not poisonous in some geographical regions in Europe, which perhaps serves to explain the conflicting reports about the edibility or otherwise of this fungus.

Another syndrome which has an extended and long latent period and in which impairment of kidney function is the primary damage is from poisoning by species of the genus *Cortinarius*. *Cortinarius orellanus* is a European species and poisoning has been reported from several countries in Europe. The key poison has been identified as *orellanin* for which a bipyridial structure has been proposed; it has also been synthesized. It is a typical nephrotoxin. In acute cases, kidney damage has even precipitated the need for kidney transplants.

A syndrome with intense bouts of perspiration coupled with salivation and lachrymation is characteristic of *Inocybe* poisoning. These effects are ascribed to *muscarine* which has been detected in several species of *Inocybe*, e.g. *I. patouillardii*. Small amounts of muscarine are known to occur in a number of mushrooms, but normally, very large quantities of these would have to be ingested for them to be able to cause any poisoning.

There are then mushrooms that are not poisonous and are edible on their own, but known to produce toxic effects when alcohol is taken after eating them. The common ink cap, *Coprinus atramentarius* is a good example. A sense of being hot and a metallic taste in the mouth accompany a reddening of the face, neck and chest: there may also be a tingling sensation in the legs and the arms,

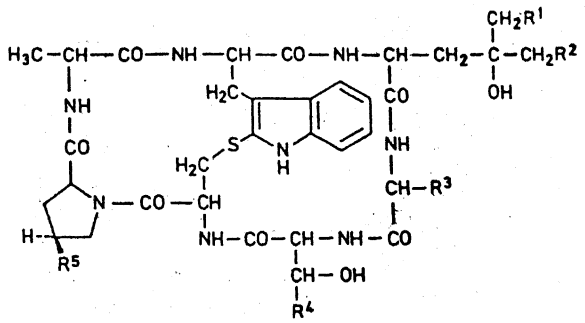
and palpitation. The active component, *coprine*, has been isolated. Coprine is an inhibitor of the enzyme, acetaldehyde-dehydrogenase in the liver: it inhibits oxidation of the acetaldehyde formed during the metabolism of alcohol to acetate. The resulting heightened content of the aldehyde in the blood shows up in the symptoms. The normal yield of coprine is about 160 mg kg^{-1} of fresh fungus. *Clitocybe clavipes* is another mushroom species that is incompatible with alcohol.



The most widely occurring syndrome from mushroom poisoning is the gastro-intestinal syndrome. According to one report 40% of all notified poisonings in Switzerland during a 40-year period were from gastro-intestinal cases. It should be noted, however, that the syndrome is heterogeneous, being due not to a single toxic species. In general, irritation of the intestinal and gastric mucosae is typical. Several species are suspect in this category: *Chlorophyllum molybdites*, *Hypholoma fasciculare*, *Megacollybia platyphylla*, *Tricholoma pardinum*, and species of *Hebeloma*, *Hygrocybe*, *Leucocoprinus*, and *Macrolepiota*. Toxic principles have been identified or isolated in some species. Thus, *Dermocybe sanguinea* contains anthroquinones such as *dermocybin* and *dermorubin* which are considered responsible. The sesquiterpene, *illudin S.* (*alunamycin*, *lampterol*) is one of the toxic principles isolated from *Omphalotus olearius*, *O. subilludens* and *Lampteromyces japonicus*. The pungency and bitter taste of species of *Lactarius* (Milk Caps) and of *Russula* (Brittle Gills) are well known. Pungency derives from sesquiterpenes, *stearyvelutinal* or *necatorone*. Some at least of these species may be rendered edible by cooking, but those tasting bitter and pungent (e.g. *Lactarius piperatus*, *Russula emetica*) are best avoided. And yet, we must note that in many parts of eastern Europe *Lactarius piperatus* is considered edible.

Poisoning is often due to ingestion of mushrooms, fresh and raw. These include, especially, the following: *Amanita rubescens*, *A spissa*, *A. strobiliformis*, *A. vaginata*, *Armillaria mellea*, *Boletus erythropus*, *B. luridus*, *Entoloma clypeatum*, *Lepiota nebularis*, *Lepista nuda*, *Russula olivacea*. These need to be cooked before being eaten. Edibility even after cooking is questionable for some species such as *Paxillus involutus* and *Sarcosphaera crassa*.

Hallucinogenic mushrooms



The fly-agaric

The fly-agaric – *Amanita muscaria* – is a mushroom that has perennially arrested our attention by its beauty and its unmistakable identity. It is quite natural that it is popularly illustrated in many a children's book. The fly-agaric is so called from its long-known property of repelling flies, a property now known to be linked to a chemical, the isoxazole, ibotenic acid, first isolated from the mushroom by Japanese scientists. The other properties of this mushroom, quite remarkable, in producing hallucinations on ingestion, have been known for a long time, for example, to the Koryaks and the Chuckchis in Siberia. Their use of this mushroom and the characteristic hallucinogenic effects which are part of the Siberian experience are remarkably well documented by travellers, historians and anthropologists: the accuracy of these accounts is matched by current knowledge of the chemistry of hallucinogenic substances in the mushroom, their metabolism in the human, and their effects on the human nervous system. Wasson reviewed knowledge of the fly-agaric with precision and elegance and even forcefully argued the case for his belief that the fly-agaric is indeed the 'soma' of the Vedas. The first bit of chemistry of the fly-agaric came from the pioneering work of Schmiedeberg and Koppe who isolated from it muscarine in 1869. Concentrations of muscarine in the fungus are, however, low and so, for muscarine poisoning to take effect, one would need to ingest unusually large quantities of fruit bodies of the mushroom. Ingestion of the fly-agaric, nevertheless, produces a characteristic syndrome in which the primary effects are neurological. The effects have been well described by many, notably in the documentation of the use and effects of the fly-agaric by the Koryaks and the Chukchis in Siberia. From its unmistakable features, wide distribution and abundance – being mycorrhizal, one may find it under pines, beech, and birch – it is one of the most widely used psychotropic mushrooms in many parts of the world, but especially in the USA. Symptoms include disturbances of vision, motor excitation, confusion that may be reflected in laughter, dancing, and singing, alteration in perception of personality, and of space and time, of colour, hallucinations, a feeling of illusion and even euphoria. Beginning within about 30 min following ingestion, all is over in about three hours. In the Siberian experience, the Koryaks in their wisdom dry the fly-agaric and it is in the dried form that the mushroom seems most effective. The active principles that are responsible for the effects are now known: apart from ibotenic acid, already mentioned, two other derivatives, muscimol and muscazone, have been discovered. Only ibotenic acid occurs as such in the fungus; the other two are secondary products that appear, for example, quite interestingly, when the fungus is dried. We must therefore assume that the heightened hallucinogenic properties of the mushroom in its dried form must be due to these secondary products. The predominant effect is inhibition of motor functions: muscimol is five to ten times more potent than ibotenic acid. Muscimol is stereochemically γ-aminobutyric acid (GABA) and so its effect on the nervous system stems from stimulation of GABA-receptors of the cells of the central nervous system. A further point of interest is, besides ibotenic acid, muscimol too has insecticidal properties.

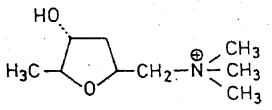
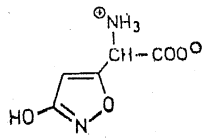
Baeocystin

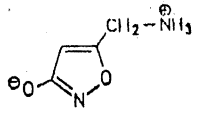
Psilocybin



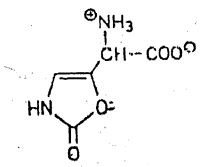
Psilocin



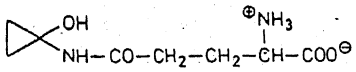
Orellanine



Gyromitrin



Muscarine



Ibotenic acid

Muscimol

Muscazone

Coprine

Chemical structure of mushroom toxins and hallucinogens

Other Amanitas that produce somewhat similar effects on ingestion are: *A. regalis*, considered by some to be only a brown variety of the fly-agaric, and *A. pantherina*, and *A. cothurnata*, all of which are known to contain ibotenic acid and muscimol.

The Psilocybes

The use of the fly-agaric by Siberian tribes finds a parallel in the ritual use of small mushrooms of the genus *Psilocybe* in Mexico. In pre-Spanish Mexico, they have long been in use to induce visions and have been called 'teonanacatl', literally, 'flesh of the Gods'. The human response to ritualistic administration of these hallucinogenic mushrooms by curanderos in Mexico is well described by Gordon Wasson from his own experience. To Aldous Huxley, the experience is: 'a state of affairs in which verbalizing and conceptualizing are in some sort by-passed. One can talk about the experience – but always with the knowledge that "the rest is silence"'. The latent period is short (15 to 120 min). Alteration of perception of time and space, a sense of elation and joy – or bliss, or alternatively (for others) anxiety and depression have been reported. The finale is a deep unconsciousness. These effects are comparable to those due to LSD (lysergic acid diethylamide) and have been amply described. Little had been known about the Mexican mushrooms until the ethnobotanical expeditions to Mexico by R. E. Schultes of Harvard University in the forties, and then followed, with the mushrooms which Schultes brought with him as the base, the pioneering and exciting studies of Gordon Wasson, mycologist Roger Heim of the Museum Cryptogamie in Paris, and Hoffman, biochemist with Sandoz in Basel on the ritual use, taxonomy and chemistry of these mushrooms, leading in essence to a remarkable synthesis of data. Roger Heim's invaluable monograph of these fungi is not only encyclopaedic but authoritative. Guzman's monograph on *Psilocybe* updates information. About 140 species of *Psilocybe* are known of which about 80 are hallucinogenic.

The largest number of hallucinogenic species are from Mexico. *P. aztecorum* var. *aztecorum* is believed to be the species used by the Aztecs. The species most popular or common in current use include *P. aztecorum* var. *aztecorum*, *P. zapotecorum*, *P. caerulescens* var. *caerulescens*, *P. cubensis* and *P. mexicana*. *P. cubensis* is coprophilous and comes up on cow dung: it is believed to have been introduced when the Spaniards brought in the cow from Africa. Several of the species can be grown in pure culture and can be cultivated. The active principle in several species is *psilocybin*, first isolated and characterized from *P. mexicana*, and also synthesized, by Hofmann. Psilocybin has the structure *N*, *N*-dimethyl-*H*-phosphoryloxytryptamine. The resemblance in structure to lysergic acid serves to explain the similarity in human response to psilocybin and LSD, already mentioned.

In nature, the unstable but related psilocin often occurs in small amounts along with psilocybin. In some species such as *P. baeocystis* and *P. semilanceata*, two other substances, also hallucinogenic, are known to occur: *baeocystin* and *nor-baeocystin*. Primarily, Psilocybe hallucinogens act as serotonin-antagonists: therefore they are used in psychotherapy and neurophysiological research. Psilocybin is active in man in very low doses: 4 mg taken orally causes wild intoxication, but 6–20 mg can elicit marked psychotropic response. Overdose can be dangerous in causing psychoses, leading to suicide mania.

Mushrooms in medicine – bioactive products

Apart from antibiotics, there are a number of substances that have been isolated from mushrooms and other basidiomycotina – substances that are variously labelled 'host defence potentiators', (HDPS), 'protein-bound polysaccharides' or 'polysaccharide–protein complexes' (PSPCs). The function of these is believed to lie in the toning up of defence mechanisms in the human system against a number of ailments. A great many of these are from polypores (Aphyllophorales) or other Basidiomycotina. At least about sixty species are traditionally used in Chinese medicine. These include species of *Ganoderma*, besides *Wolfiporia cocos*, *Polyporus mylittae*, *Fomitopsis officinalis*, *Coriolus versicolor*, *Fomes fomentarius* and *Bjerkandera fumosa*. *Tremella fuciformis* (Basidiomycotina, Tremellales) and *Coriolus versicolor* (Aphyllophorales) are used in Chinese folk medicine for their nutritive and tonic properties in the treatment of debility and exhaustion.

Ganoderma lucidum, *ling-chi* in Chinese folk medicine, is highly valued in China and in Japan for its medicinal properties and its ingredients, considered both a tonic and a panacea for a variety of ailments neither specific nor specifiable. An almost magical effect on intelligence, enhancing memory, and hearing, vision and smelling, has been attributed to this fungus. In practice, only the fruit bodies of *G. lucidum* and *G. japonicum* are used, the spores are discarded. During the past two decades there have been several studies on the chemistry of bioactive substances in *ling-chi* and the human response to these substances, but more specially their potential use in the control of a number of specific diseases such as cancer, diabetes and hepatitis. The spectrum of bioactive substances in *G. lucidum* includes organic germanium, polysaccharides (B-D-glucans), triterpenoids and adenosine.

Host-mediated anti-tumour polysaccharides of *G. lucidum* have been patented as immunopotentiators in the treatment of cancer. Besides, *G. lucidum*, *G. tsugae* and *G. boninense* are included in Japanese and US patents. Also, over one hundred novel, highly oxygenated, lanosa-type triterpenoids have been reported from fruit-bodies and mycelium of *G. lucidum*: their chemical structure has been determined. These include: ganoderic acids, gan-

oderemic acids, ganodermic acids, ganoderal, lucidernic acids and lucidone and ganoderols. It is tempting to speculate if these diverse triterpenes could explain the multiple beneficial effects for which *ling-chi* is reputed.

A freeze-dried powder containing mycelium of *G. lucidum* has been shown to bring down blood sugar levels in experimental diabetic rats. Three hypoglycaemic principles, *ganoderans* A, B and C have been isolated from fruit-bodes: these are characterized as peptidoglycans. Of these, ganoderan B is considered to be the major one.

Extracts of the fungus have also been shown to be hepato-protective: apart from liver regeneration, beneficial effects against hepatic necrosis and hepatitis have been noted. *Ganodosterone* from *G. lucidum* is a liver-protectant and stimulates liver function. Similarly, ganoderic acids T, S and R, from the mycelium of the fungus are hepato-protective. Hepato-protective triterpenoids have also been isolated from *G. tsugae*: lucidone A, lucidenol, ganoderic acid B, and ganoderic acid C2.

Ganoderma is cosmopolitan; some species cause serious decay in wood; some are root-disease pathogens of a variety of plantation crops and are economically important. Some species have the ability to selectively degrade lignin and so are a potential source of lignin-degrading enzymes useful in the bioconversion of lignin in agricultural and other wastes. The new wave of interest in *Ganoderma* has prompted studies on taxonomy, distribution, and even speciation. The low nucleotide variation observed in the 25 S rDNA and the very high transition bias in the region suggest that the genus is young and is still evolving.

Lentinan from the edible mushroom, *Lentinus edodes* has been shown to have distinct anti-tumour properties and has also potential use in enhancing host resistance to a variety of infections, including HIV-1 or AIDS. *Lentinus edodes* is remarkably effective in lowering levels of lipids in the blood: the hypolipidemic effects are due to a secondary metabolite identified as 2(R), 3(R)-dihydroxy-4-(I-adenyl)-butyric acid which has the trivial name *eritadenine* (=*lentysine, lentinacin*). A lowering of serum cholesterol levels in man has also been reported.

Mushrooms: antiquity, speciation

The oldest known fossil mushroom species is perhaps *Coprinites dominicana* described as trapped in amber about 40 Mya. Mushrooms are believed to have radiated in the Cretaceous about 130 Ma, after the great rise of the angiosperm land flora. Ectomycorrhizal fossil mushrooms date back to the same time.

In the case of *Pleurotus* (the oyster mushroom) compatibility tests have shown the existence of several distinct intersterility groups (biological species). Recent work on speciation, from phylogenetic analysis of ribosomal DNA sequences among these intersterility groups, indicates that several species lineages evolved quite early: species lineages of more recent origin appear to be restricted in distribution, viz. to the northern hemisphere. Older lineages, on the other hand, have a distribution world-wide. The explanation for this pattern of distribution may well be that the old lineages were extant before the break-up of 'continents' from drift, and new lineages arose in the northern hemisphere following continental drift. On the other hand, one might also postulate dispersal as the primary factor governing the current distribution pattern. Whichever of these two postulates we accept, it is clear that older lineages have a wider distribution and more recent lineages have relatively narrower distribution, some thing akin to Willis's Age and Area hypothesis. Genetic divergence appears to be linked to allopatric speciation within populations from different continents in the northern hemisphere.

This contribution is but a feeble attempt to capture and present for the reader something of the beauty, diversity, and relevance of mushrooms. The literature on the subject is enormous and an account like this cannot be anything but incomplete. The list of selected references appended here should, however, help the reader to delve deeper into the subject. And, it would give me great joy if what I have written and presented provokes curiosity, further probing into 'mushroom science' and, most important, evokes excitement, fascination and wonder.

RESEARCH ARTICLE

Role of fluorescence microscopy in the assessment of Indian Gondwana coals

Bhagwan D. Singh

Birbal Sahni Institute of Palaeobotany, GPO Box 106, Lucknow 226 001, India

When a light of short wavelength excites organic matter, light of relatively longer wavelength is emitted from it and this phenomenon is known as autofluorescence. The coal maceral analysis under fluorescence mode (blue light/UV light excitation), therefore, has been found to be best suited to properly identify, characterize and quantify hydrogen-rich macerals. Utilizing this technique, macerals like bituminite, fluorinite and exsudatinite were recognized for the first time. Certain other macerals – alginite and liptodetrinite, normally mistaken for mineral matter under routine petrographic analysis, were also identified. Fluorescence microscopy, thus, not only added to the overall tally of liptinite group of macerals in Indian Gondwana coals, but also to their quantity. In addition to this, recognition of fluorescing vitrinite (perhydrous vitrinite) significantly contributed to the abundance of hydrogen-rich microconstituents for these coals.

FLUORESCENCE microscopic study of solid fossil fuels (coals/lignites) and kerogen (in sedimentary rocks) has been found quite successful particularly in identification, characterization and quantitative assessment of hydrogen-rich macerals, especially the liptinite (or exinite) group of macerals. It is a useful technique for determination of rank or maturity and even better suited in cases where vitrinite/huminite macerals are not in sufficient quantities or not suited for reflectivity measure-

Presented at 'Contemporary Research Trends in Palaeobotany' to commemorate The Palaeobotanical Society International Medal Award function, BSIP, Lucknow, January 12, 1993.

ments, e.g. sapropelic coals, bog-head coals, oil shales, kerogen, etc. It affords a quantitative estimation of spectral fluorescence emission which is characteristic of both the individual maceral as well as rank/maturity and enables easy and reliable distinction of liptinites.

The liptinite maceral group, which is chemically distinguished from its two precedents – inertinites (relatively carbon-rich) and vitrinite (relatively oxygen-rich) by its relatively higher hydrogen content, is particularly heterogeneous in its biological origin. Because it mixes organs (or fragments of organs) and plant organisms: these are, on the one hand, spores–pollen grains (sporinite), cuticles (cutinite) and certain epidermal tissues, plant secretions – resins (resinite), essential oils, etc. and, on the other hand, the immense class of algae (alginite). Certain other liptinite macerals originate during coalification process, e.g. liptodetrinite, fluorinite, bituminite; derived from bacterial substances and decomposition products (Table 1), besides a secondary maceral – exsudatinite. Plants lipids, proteins, cellulose and other carbohydrates are characteristic source materials of liptinites[1].

Evidently, various liptinite macerals having different modes of occurrences and chemical properties behave differently under fluorescence mode and their fluorescence characteristics are correlatable with rank stages. They are all characterized by a fluorescence which takes on various colouration according to their nature and their rank; the intensity of this fluorescence decreases with the increasing rank and disappears towards 1.0 to 1.3% R_0 max[3,4]. Since the fluorescence property of organic matter or maceral is the reflection of its overall chemical characteristics, the technique helps in understanding the changing pattern of macerals through various coalification stages.

Gondwana coals are normally rich in mineral matter/ash contents. Also their liptinite contents recorded under normal reflected light is quite low (usually 1–15%). In fact, high inherent clastic minerals intimately associated with these macerals in the coals tend to mask them, at times completely, rendering their identification difficult or even impossible under normal incident light. Earlier, only macerals like sporinite, cutinite, suberinite and resinite were subnormally recorded, whereas liptodetrinite, alginite, fluorinite, bituminite, etc. were normally mistaken for mineral matter. It is primarily because of this reason that mineral matter-rich Lower Gondwana (Permian) coals of India were and are still considered to be poor in liptinite contents.

In the past few decades it has been realized that chemical properties of Permian coals, viz. carbonization, swelling index, liquefaction, etc. do not correspond well with the biopetrological results under normal reflected light. The explanation was not possible till the use of fluorescence microscopy came into routine service, by which hydrogen-rich macerals quantities show a manifold increase in the same coals. It is the intention of this communication to highlight the advantage of fluorescence microscopic method in evaluation of certain Lower Gondwana coal seams from Raniganj, Singrauli and Rajmahal fields of India.

Table 1. Classification of coal maceral groups/macerals and their source material. (ref. 2, modified after ref. 1)

Group	Maceral	Origin
Vitrinite	Telinite	Cell walls (may be resin impregnated or lignified) rich in cellulose.
	Telocollinite	Gelified plant tissues.
	Desmocollinite	Gelified humic detritus (amorphous).
	Vitrodetrinite	Humic detritus.
	Corpocollinite	Cell filling (oxidation/condensation products of tannins or biochemically gelified humic matter).
Liptinite or Exinite	Sporinite	Spores and pollen exines of higher plants.
	Cutinite	Outer layers of leaves, needles, shoots, thin stems of higher plants.
	Suberinite	Suberinized cell walls (bark or cork cells).
	Resinite	Resin, balsam, copal, latex, wax, oils and fats from higher land plants.
	Fluorinite	Essential oils of higher land plants.
	Alginite	Colonial and unicellular algae.
	Bituminite	Anaerobic biodegraded products (amorphous microbial, algal and/or faunal remains).
	Chlorophyllinite	Chlorophyll.
	Liptodetrinite	Biodegraded or detrital liptinite macerals and/or phytoplanktons and algae.
	Exsudatinite	Secondary exudates.
Inertinite*	Fusinite	Cell walls (charred, oxidized or fungus-infested).
	Semifusinite	Cell walls (partly charred, oxidized, or fungus-infested).
	Sclerotinite	Fungal hyphae, mycelia, spores and sclerotia.
	Macrinite	Amorphous gel (oxidized/microbial metabolic products).
	Inertodetrinite	Detritus of above inertinite macerals.
	Micrinite	Secondary relics of oil generation (mostly).

*A small part of inertinite originates from melanin-rich plant and animal material – 'primary inertinite'. A greater part attains its inertinitic properties during early coalification process – 'rank inertinite'.

Materials and method

In principle, irradiation or excitation with a light of short wavelength, routinely blue or ultra-violet light, on organic matter or maceral causes emission of fluorescence colours and this phenomenon continues till stoppage of excitation – 'auto-fluorescence'. During auto-fluorescence, emitted colour and intensity changes with time and this dual change is known as 'alteration effect'. Alteration of fluorescence colour and intensity are typical of a particular organic matter or maceral at a given

rank or maturity stage. Based on these criteria, various types of organic matter/macerals are identified and characterized.

Maceral content was determined under blue light excitation (filter block H3:420-490 nm, violet-blue excitation) on Leitz MPV-3 unit using 150 W ultra high pressure xenon lamp (to initiate fluorescence) as source of illumination, 25× NPL Fluotar objective (oil) with a 0.75 numerical aperture and fluorescence-free immersion oil. The reported results, based on 500–1000 point counts per sample, are expressed as volume per cent of the various fluorescing and non-fluorescing macerals on a mineral matter-free basis.

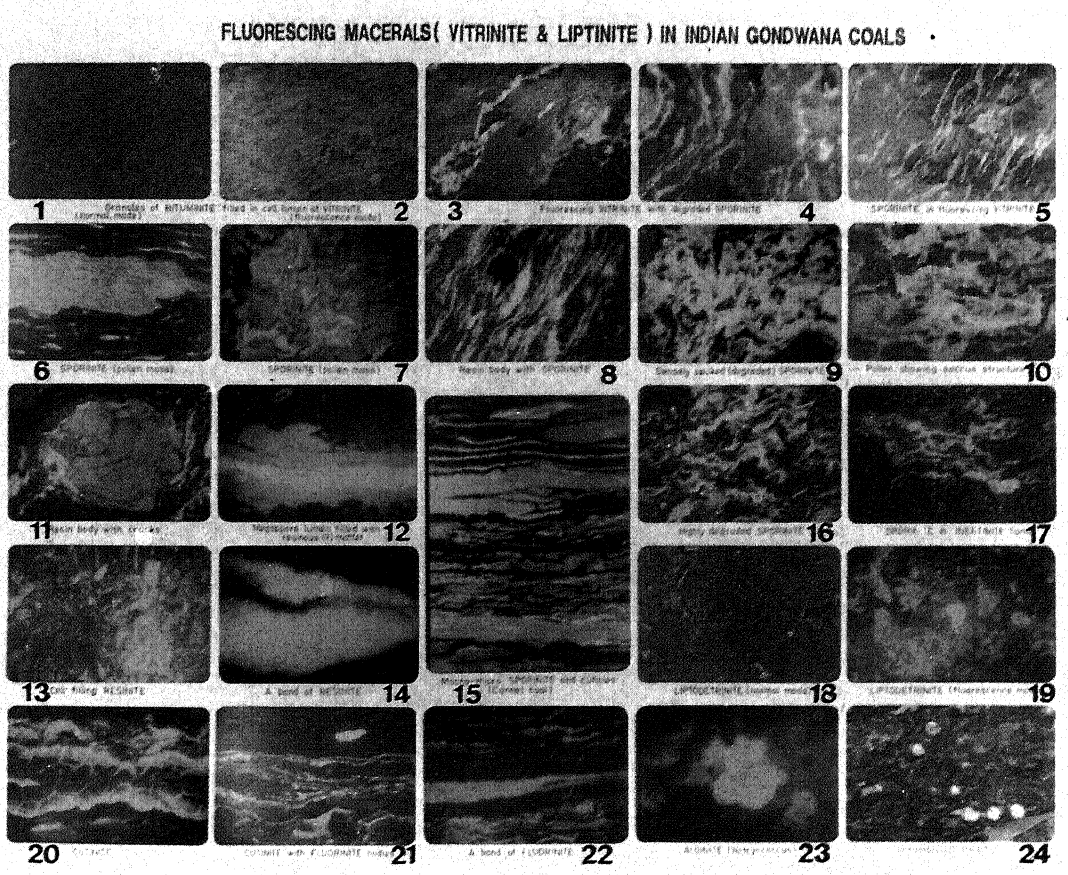
A total of 192 particulate coal pellets prepared by cold embedding in epoxy resin were analysed by coal petrographic procedures. Some pertinent details about number and nature of samples, name of coal seams and their respective coalfields are given in Table 2. The coals range in rank between sub-bituminous A to high volatile bituminous C–A stages (R_0 max. 0.40–0.88% in oil).

Table 2. Details of coal samples studied from some Lower Gondwana coalfields of India

Late Permian – Raniganj Formation
Raniganj Coalfield (Damodar Basin), West Bengal
Three bore-hole sections from:
Girmint block (bore-hole TAD GRT/0160/CM-009)
Seam nos. (bottom to top): I, II, III bot., III top, IV, Bankshimulia, V, VI, Century, VII, VIII bot., VIII top, Kusudanga, IX, XA and X (16 samples)
Dhemo Main block (bore-hole DMM/0030/CM-006)
Seam nos. (bottom to top): VA, V, VI bot., VI mid. VI top, VIIA, VII, VIII bot, VIII top, IX and X (11 samples)
Shyamsunderpur block (bore-hole SS-5)
Seam nos. (Bottom to top): IV, V, VI, VIIA, VII, VIII bot., VIII mid., VIII top and IX (9 samples)
Singrauli Coalfield (Son Basin), Madhya Pradesh
One bore-hole section of Jhingurdah seam from:
Jhingurdah colliery (bore-hole NCSJ-4)
Top seam (41 samples)
Bottom seam (6 samples) (47 samples)
Early Permian – Barakar Formation
Singrauli Coalfield (Son Basin), Madhya Pradesh
Five sections of Turra seam from:
Kakri (10 samples), Bina (11 samples), Jayant (8 samples),
Gorbi (16 samples) collieries and bore-holes NCSM-3 (Moher block-15 samples) and CMSA-111 (block-B-7 samples) (67 samples)
Chuperbhita Coalfield (Rajmahal Basin), Bihar
One bore-hole section from:
Chuperbhita basin (bore-hole RCH-3)
Seam nos. (bottom to top): I (samples), II (9 samples), III (6 samples) IV (4 samples), V (3 samples), VI (3 samples), VII (3 samples) and VIII (9 samples) (42 samples)

Caution

It must be mentioned here that in identifying organic matter/coal macerals in fluorescence mode, one should have proper morphological knowledge. There are some minerals, viz. calcite, siderite, fluorite, a variety of quartz, etc. which fluoresce and can be mistaken for resinite and cutinite macerals. Certain translucent minerals, such as clay, because of internal reflection/refraction appear green, yellowish-green to yellow colours giving a false impression of being resinite. Beside this, embedding medium being a chemical substance, does react with embedded coal particles producing yellowish-green – yellow to yellowish-orange colours and, thus may add to the tally of resinite.



The quantitative evaluation of macerals under fluorescence mode may tend to give an over estimate of fluorescing matter. This is because of the fact that some of the short wavelength light penetrates into underlying coal and, thus generates three-dimensional image of macerals below the polish surface of the grain mount. Therefore, quantitative estimation of macerals, especially the liptinite macerals, in mineral matter-rich coal samples may represent over estimated results. However, in clean coals this factor may not apply at all.

Characteristic features of fluorescing macerals

Perhydrous vitrinite and all the macerals of liptinite group were the fluorescing macerals in the Lower Gondwana coals of the Raniganj, Singrauli and Rajmahal coalfields. Corpocollinite and a fraction of telocollinite macerals of vitrinite group and macerals of inertinite group were non-fluorescing in these coals.

Sporinite is derived from the outer cell walls of spores and pollen. It fluoresced with orangish-yellow, yellowish-orange, brownish-yellow to yellowish-brown colours in studied Gondwana coals. The sexinal part of the spores and pollen fluoresced with relatively brighter colour than the nexinal part bordering streaky slit- or thread-like lumen. Both tenui- and crassi-sporinites were present along with sporadic to common macrosporinite (Figures 12, 15). The microsporinite in coals was either sparsely distributed (Figures 3, 4) or was packed densely in thin to thick microbands (Figures 5, 8, 15, 22), especially in dull coals. Densely packed sporinite as thick microbands were frequent in Singrauli[2] and Rajmahal coals, where a part of dull bands evidently developed into semi-cannel or cannel coals. This is the first record of the presence of semi-cannel/cannel coal bands in India. The sporinite-rich bands were usually poor in the inertinite macerals which occurred randomly as pieces and fragments (Figure 17).

The Lower Gondwana coals commonly contained gymnospermous pollen-mass or pollen in sporangium with or without sporangial covering/wall in unreleased stage (Figures 6, 7). In normal light, such dark grey

Figures 1, 2. [All photomicrographs were taken on polished surface under incident blue light excitation (except nos. 1, 18 and 24) using oil immersion]

densely clustered sporinite was earlier misidentified either as calcite mineral or resinite maceral by others. The individual pollen of the pollen-mass are tightly packed together so that their outline is generally obscured but their lumen can invariably be recognized.

During the investigation, it was observed that sporinite showed wide variety of preservational stages from well-preserved to highly degraded and fragmented (Figures 9, 10, 16). During biodegradation the pollen appears to have disintegrated into smaller pieces by granulation and ultimately got reduced to fine granular mass of liptodetrinite. Mechanical breaking of pollen with or without biodegradation also led to liptodetrinite formation. Another form of sporinite degradation noticed was by *in situ* pyrite growth where pyrite crystals tended to grow inside the pollen saccus, rupture it by blistering the saccus wall, thus facilitated further biodegradation and mechanical breaking.

Cutinite is derived from cuticles and cuticular layers which occur at the surface of leaves, twigs, and other areal parts of plants as a protection from dessication. It showed brownish-orange to orangish-brown colours with relatively weaker fluorescence intensity than the sporinite in these coals. Both tenui- and crassi-cutinites were observed generally in well-preserved state (Figures 15, 20). Cutinite enclosing certain tissue structure, such as leaf sections, was normally associated with fluorinite which appear as irregular amorphous bodies of various dimensions (Figure 21).

Fluorinite originates from essential oils and lipid-rich cell inclusions of various sources. It occurs as blobs or blotches, streak and lensoid bodies or as thin bands and

Table 3. Maceral composition (mean and range) and reflectance value of the coal seams from the studied fields of India

	Raniganj Coalfield	Singrauli Coalfield		Rajmahal Coalfield

having strong fluorescence intensity (of bright orangish-yellow to yellowish-orange fluorescence colours; Figures 21, 22). Such fluorinite bodies can be easily mistaken for resinite even in fluorescence mode, unless their rapid alteration is ascertained. Because of indefinite morphology, amorphous nature and characteristic colour (dark grey), the maceral fluorinite is unidentifiable under normal light and is mistaken for voids or translucent minerals.

Suberinite is derived from suberin layers of corkified cell walls, mainly in tree barks. Suberin is formed also at the surface of roots and fruits, acting as a protection against dessication. The maceral suberinite fluoresced with weak orangish-brown colour and was only sporadically observed in these Gondwana coals.

Alginite represented by *Botryococcus* was commonly observed occurring discretely or in clusters in well-preserved to highly degraded conditions. Well-preserved alginite was not observed in the Late Permian coal seams. It fluoresced more strongly (with orange colour) than other liptinites and showed rapid alteration. In degraded condition it was recognized by its characteristic fluorescence colour, intensity and relict morphology. Alginite appearing as dark grey and black coloured discrete globular or small lumpy bodies with granular texture under normal reflected light has been misidentified as mineral lumps. Presence of *Botryococcus* in Singrauli (persistent[2]) and Rajmahal (common) fields is the first authentic record from the Palaeozoic coals (Figure 23). It seems that these coals contain a fair amount of alginite, most of which was later degraded and incorporated in perhydrous vitrinite. Contribution of alginite to humic coals in fair amounts has already been recognized by Stach *et al.*[5]

Resinite is derived not only from resins but also from balsams, latexes, fats and waxes. It is characterized by variable fluorescence intensity and colour than any other liptinite macerals in a given coal. It occurred as discrete oval, elliptical or elongated bodies with regular or irregular margins of various dimensions (usually small) in Gondwana coals (Figures 8, 11, 13, 14). Macerals such as collinite in telocollinite/desmocollinite as thin micro strips, streaks or stringers in bi- and trimaceral associations have almost identical light to dark grey colours as that of resinite and cutinite under normal light. It is for this reason that there is a possibility of misidentification of certain vitrinite maceral as resinite. In addition to this, transluscent white or pale yellow clay blobs or blotches normally non-aligned with the surrounding macerals, as has already been mentioned, are likely to be mistaken as green or yellow resinites in fluorescence mode.

In fact, green or yellowish-green resinites were not recorded in these coals. Greenish-yellow resinite was rare and that fluoresced with yellow colour was sporadic as expected according to rank of these Gondwana coals.

Greenish-yellow to orange fluorescing resinites were generally translucent, whereas brown resinite appeared opaque. With increase in rank, it has been proved in Indian coals and lignites[6] that resinite fluorescing with green, yellowish-green or greenish-yellow and yellow colours gradually become less common, being overtaken by orange and brown colours (including transitionary colours).

Liptodetrinite is a common product of anaerobic microbial degradation and disintegration of liptinite macerals, chiefly sporinite, possibly alginite and certain amount of cutinite in these coals. Participation of resinite maceral in liptodetrinite formation was not recognized in studied coals. Because of its highly degraded nature and lack of morphology, the maceral is normally mistaken for mineral matter-rich patch under normal incident light (Figures 18, 19). Its recognition is routinely possible under fluorescence mode only.

Bituminite is the product of anaerobic biodegradation formed in coals as a result of 'bituminization' during biochemical gelification stage between vitrinite R_0 max. >0.40 to 0.50% (ref. 7). It is an amorphous (unstructured) maceral of liptinite group with brownish fluorescence colour of weak intensity. This maceral is properly recognized only under fluorescence mode. Normally, the bituminite formed is pervasively impregnated in the pore spaces of vitrinite rendering it perhydrous in nature (Figures 1, 2). Therefore, most of the bituminite present in a coal is accounted for alongwith perhydrous vitrinite (imparting weak to moderately weak reddish-brown fluorescence colour) including desmocollinite groundmass. Sometimes granules of bituminite were observed packed densely inside the original cell lumens of vitrinite separated by non-fluorescing cell walls. Presence of alginite in studied coals indicate that significant amount of bituminite was generated by alginite as well.

Exsudatinite originates as fluid substances expelled from lipid-rich parent material (in vitrinite, fluorinite, resinite, etc.) during 1st coalification jump. Appearing as migrated bitumen, in coals it fills open cleats, fissures and pores. The formation of exsudatinite is often associated with oil expulsions in the form of smear films and as droplets exuding/oozing from cleats in vitrinite. These oily exudates are not considered as maceral by Teichmüller[8]. In studied coals, exsudatinite and surface films were only sporadic in occurrence and fluoresced with weaker intensity than sporinite and some of the cutinites in orangish-brown or brownish-orange colours. In low rank coals, exsudatinite and oily droplets appear brown or dark grey in colour under normal light, whereas the smear films often show rainbow colour bands. This secondary maceral is properly recognized only under fluorescence mode.

Biopetrographic composition of coals

The coal seams of Barakar Formation from Rajmahal and Singrauli fields are normally rich in inertinite (6.0–72.0%) and the vitrinite ranges between 3.6 to 80.8%. The Raniganj coal seams (from Singrauli and Raniganj fields), on the contrary, contain high vitrinite (25.0–77.0%) and relatively low inertinite (4.2–26.6%). These Gondwana coals are characterized by persistently low (1.0–13.6%) and randomly distributed liptinite contents (Table 3). Associated minerals are usually fine black granular argillaceous matter, besides siderite, calcite and pyrite minerals, commonly found dispersed and intimately associated with organic constituents.

Under blue light excitation, the coals of both Barakar and Raniganj Formations were found to contain appreciably high amounts of liptinite macerals (7.0–66.2%) and perhydrous vitrinite (6.0–80.2%). However, the coal seams of the Barakar Formation are characterized by higher proportions of liptinite macerals, especially the sporinite (4.9–58.0%) than the coal seams of the Raniganj Formation (4.8–39.7%), whereas the coal seams of the latter formation have higher proportion of perhydrous vitrinite (19.0–64.0%) than those of the former (2.0–80.2%). The liptinite macerals in these coals are formed chiefly by sporinite (4.8–58.0%) and liptodetrinite (1.2–20.0%). Cutinite, suberinite, resinite, exsudatinite and fluorinite are other liptinite macerals together occurring in only subordinate amounts. Maceral bituminite being associated with perhydrous vitrinite and liptodetrinite was not recorded separately. Presence of maceral alginite was commonly recorded (up to 0.8%) in the Barakar coal seams.

It must be mentioned here that Chakrabarti[9], Chaudhuri and Ghose[10], and Saxena *et al.*[11] carried out fluorescence microscopy of certain Indian Gondwana coals. However, their petrographic data in certain specific aspects do not correspond well with those obtained presently. Therefore, it has been deemed necessary to explain the reasons of the discrepancies between the two data sets.

Chakrabarti[9] has evaluated representative coal samples (seams) from various Gondwana fields and remarked that 'higher-volatile bituminous coals (VM >40%) with reflectance values varying from 0.45–0.65% do not show any fluorescence property in primary structured constituents like vitrinite and fusinite'. Absence of fluorescing (perhydrous) vitrinite in this rank range is surprising, even coals having abundant liptinites. However, desmocollinite and a fraction of telocollinite (of vitrinite group) were presently found to be fluorescing with dull reddish-brown to dark brown colours, although with weak intensity.

The bituminite recorded by Chaudhuri and Ghose[10] (Figure 7) does not conform to its characteristic morphology. It is more like a resinite, whereas 'greenish-yellow' colour of the associated exsudatinite (in same figure) is rather surprising for high volatile bituminous coal rank. They also recorded crack-filling fluorinite. Actually it is not a crack-filling maceral. As is clear from their figure (8a, p. 248) it is an embedding medium between two coal particles and a crack in one of them.

Saxena *et al.*[11] carried out analysis of Raniganj coal seams (R-I – R-X) from the Raniganj field. They have not, however, provided information about the location and sequence of samples, lateral representation of coal seams and fate of split seams, besides coal quality and rank. Therefore, generalization made on the coal seams (for the coalfield) by them is unacceptable. Absence of cutinite under blue light excitation (Table 2, p. 61), but their presence in certain seams under normal light (Table 4, pp. 66, 67) is surprising. More than 5–10% (m.m.f) of resinite and 65 to above 69% (m.m.f.) of perhydrous vitrinite contents reported by Saxena *et al.*[11] (Table 2) is also abnormally high. Such high quantities of perhydrous vitrinite is not recorded even in Tertiary coals of Assam which are best suited for liquefaction[12]. High resinite content (5–10%) in coal seams R-II, R-III, R-VII to X recorded by Saxena *et al.*[11] is because of wrong identification of macerals collinite, desmocollinite, corpocollinite and sporinite and calcite, siderite and a certain fraction of clay minerals as resinite. The following are some examples from the illustrations of Saxena *et al.*[11] to support my contention:

(1) Plate 1, Figures 1, 2, 4, 5: the resinite (R) shown are collinite-filled lumens of telocollinite.

(2) Plate 3, Figure 2: resin (R) fillings and bitumen (B) shown are sporinite and calcite respectively. Figure 4: is not resin fillings in irregular spaces but sporinite in desmocollinite.

(3) Plate 4, Figures 1, 2, 6: are not resinite (R) but anisotropic siderite whose dark grey portions were identified as resinite. Refer siderite concretion in Plate 5, Figure 1. Figures 3, 4: are not resinite but corpocollinite and desmocollinite (in trimacerite) respectively. Figure 5: is calcite not resin (R) content filled in elliptical shape.

(4) Plate 5, Figure 3: is a pollen-mass (sporinite) not resin (R) fillings along the cracks. Note sporinite lumens are clearly discernible.

(5) Plate 6, Figures 2,3: illustrate green resinite (GR) which, in fact, are voids of fusinite lumen filled with embedding medium. Green to orange resinites do not fluoresce with such weak intensity. Figure 4: is not yellow resinite (YR) but oily droplets (exsudatinite) oozing out from a crack in vitrinite. Figure 5: illustrates two identical patches one (arrow pointing orange colour thread-like structures which is, in fact, lumen) recognized as sporinite (S) and the other (arrow pointing coalesced sporinite walls) as yellow reactive resin (YR)/hydrocarbon. In fact, both of them are pollen-mass (sporinite). Sporinite wall can never become resinite. Figure 6: is not green reactive resinite (GR) filled in fusinite lumen. Instead it is either embedding medium (epoxy) or fine clastic mineral with internal reflection. Such examples are frequently observed in Permian coals. Figure 8: is more like exsudatinite (mark the morphology and nature of encroachment on the associated macerals) rather than yellow to orange colour reactive resin (YR) filled along vitrite cracks. Figure 9: is not a lath-shaped resinite (R) body but a blob of clay mineral showing its characteristic internal striations. The body is not in alignment with the surrounding sporinites, which clearly indicates it to be a secondary matter. Figure 10: shows yellow resinite (YR) filled in sporinite. In fact, if properly focussed it will reveal 3–4 sporinites compressed together.

No resinite (resin) as that shown in black and white photographs (Plates 1, 3–5) have been illustrated under fluorescence mode. Calcite is a weakly fluorescing mineral and can be mistaken as resinite. Absence of corpocollinite, cutinite and calcite and low amount of siderite recorded clearly explain the reasons for high amount of resinite erroneously recorded by Saxena *et al.*[11] in the Raniganj coal seams of the Raniganj field.

Conclusions

Utilizing the fluorescence technique, macerals like liptodetrinite, bituminite, exsudatinite, alginite and fluorinite, in addition to fluorescing or perhydrous vitrinite, have been recognized for the first time in Indian Lower Gondwana (Permian) coals of the Raniganj, Singrauli and Rajmahal fields. Thus, these not only add to the number of liptinite macerals but also to their quantity (2–4 times or even more than recorded in normal incident light). This positively indicates that the earlier 'liptinite-poor' concept for Indian Gondwana coals is no longer tenable. High concentration of especially sporinite in some coal bands of Singrauli and Rajmahal fields make them of cannel/semi-cannel coals types.

Reduced uptake of (^{3}H) thymidine by PHA-responsive human peripheral blood lymphocytes as a function of storage

Awadhesh N. Jha

Centre of Advanced Study in Zoology, Banaras Hindu University, Varanasi 221 005, India
Present address: Brixham Environmental Laboratory, ZENECA Limited, Brixham, Devon TQ5 8BA, UK.

Phytohaemagglutinin (PHA)-responsive lymphocytes from human peripheral blood samples, either irradiated or unirradiated, showed a reduced frequency of (^{3}H) thymidine-labelled cells (detected by autoradiography) as a function of storage duration. The study indicated that storage of blood samples could lead to a delay in the initiation of cell cycle progression and may impart additional source of variability when these cells are used for experimental or clinical purposes.

PERIPHERAL blood lymphocytes (PBL) of human are widely used for clinical and experimental purposes. One of the most widespread uses of PBL is in environmental mutagenesis studies. In such studies, these non-dividing cells are stimulated to divide by mitogens such as phytohaemagglutinin (PHA), under *in vitro* conditions, in order to analyse chromosomal aberrations (CAs) and sister chromatid exchanges (SCEs) from individuals occupationally or accidentally exposed to mutagenic agents. In such studies, CAs and SCEs are analysed respectively from cells which have divided once (first division or M1 cells) or twice (second division or M2 cells) in culture following PHA-stimulation[1]. It is well known that under *in vitro* conditions, a large number of factors influence the cell cycle kinetics of these cells. It is essential to recognize and take into account such factors when biological dosimetry and genetic risk evaluation are made. In this context, it is not always possible to use the blood samples immediately after their collection. A delay, therefore, is inevitable between collection of blood samples and setting up of the cultures especially when they are to be transported from distant places. Only a few reports are available on the effect of storage duration on cell cycle progression of these PHA-responsive cells.

Introduction of fluorescence plus Giemsa (FPG) staining technique[2] has facilitated the identification of cells which have divided once or more[3]. This technique as a prerequisite requires thymidine analogue, 5-bromodeoxyuridine (BrdU), when cells are grown in cultures. Using this technique, increased proportion of M1 cells and subsequent reduction in the frequency of other division cells was shown from the cultures of stored blood samples compared to fresh ones which were irradiated prior to setting up the cultures[4]. In another study on unirradiated blood samples, an increase in the proportion of M1 cells was also noticed as a function of storage duration[5]. It was suggested that when stored blood samples are used for cultures either there is a delay in cell cycle progression[4,5] or a failure in the differential uptake of Giemsa stain by the chromosomes of M2 and subsequent division of cells, leading to misidentification of M2(+) cells as M1 cells[5]. It was also recommended that when blood samples are stored for a day or more, increased amount of BrdU should be added in the cultures for proper differential staining of the chromatids[5]. We, however, found that PHA-responsive lymphocytes, either irradiated or unirradiated, show increased frequency of M1 cells as a function of storage duration. Increasing BrdU concentrations slowed down the cell cycle progression and its higher concentration was not required to elicit proper sister chromatid differential staining when cultures were set up from stored blood samples[6]. The study therefore suggested that storage condition delays the cell cycle progression of these PHA-responsive cells.

In order to check if there is any change in the programme commitment of these cells for the initiation of proliferation due to storage condition which could be responsible for increased proportion of M1 cells, in the present study, an attempt was made to analyse (^{3}H) thymidine uptake by these cells (as a function of storage duration) following mitogen stimulation. Autoradiographic technique was used to analyse (^{3}H) thymidine uptake by lymphocytes from both unirradiated and irradiated blood samples to corroborate our earlier cytogenetic findings[6]. Needless to say, this sensitive technique is being widely used in regulatory and scientific studies to identify mutagenic hazard by measuring unscheduled DNA synthesis (UDS). In these studies, radiolabelling is determined by counting the number of silver grains which develop over the cells[7,8].

Blood samples were collected from two healthy donors using heparnised syringes. Each sample was divided into three equal parts as per storage requirement (0, 1 and 3 days). The fresh blood samples were irradiated with a dose of 2 Gy of X-ray (110 kV 4 mA, @1 Gy min^{-1} at 37°C). Irradiation was performed within 2 h of collection under aseptic conditions at normal atmospheric pressure in 25 ml glass beakers (in the presence of atmospheric oxygen). After 2 h incubation at 37°C, the irradiated blood samples were used for culture. Other two parts of the sample were stored at room temperature (22 ± 2°C) in a biochemical oxygen demand (BOD) incubator and used for cultures after 24 and 72 h (1 and 3 days) respectively. Unirradiated blood samples from both the donors were also used parallel to the irradiated blood samples. Cultures were initiated by adding 0.30 ml of irradiated or unirradiated blood in 5 ml of

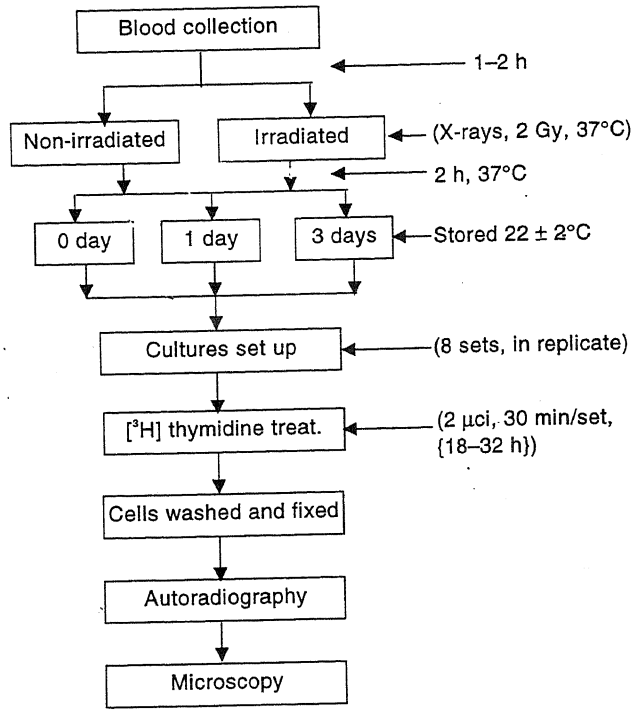

Figure 1. Experimental protocol to study the effect of storage duration on (^{3}H) thymidine uptake by phytohaemagglutinin (PHA)-responsive peripheral blood lymphocytes (PBL).

Eagles minimum essential medium, supplemented with antibiotics, 20% heat-inactivated human AB$^+$ serum and 0.15 ml of PHA (HA 15 Wellcome Reagent Ltd, UK), as described elsewhere in detail[6]. The experimental protocol has been summarized in Figure 1.

As a pilot autoradiographic study, to check the origin time of incorporation of (^{3}H) thymidine in our culture conditions, 12 cultures (in duplicate) were set up from freshly collected blood sample. A 30 min (^{3}H) thymidine pulse (2 µCi ml^{-1}; specific activity 6 Ci Mm^{-1}; BARC, India) was given to these cultures at hourly intervals beginning from 12 h of PHA stimulation up to 24 h. The cells were then fixed in methanol:acetic acid (3:1) followed by very brief washing (2 min) with cold hypotonic (0.56% KCl). Air-dried slides were prepared and processed for autoradiography. The slides were treated with 10% chilled trichloroacetic acid for 5 min, rinsed twice in ethanol and kept under running water for 10 min. After coating with 1:1 dilution of Ilford L4 nuclear emulsion in safe light, the slides were left for exposure in light proof boxes at 4°C for 20 days. The slides were developed in Kodak D 19b developer for 10 min at 10°C and fixed in acid fixer. After drying, they were stained lightly in 2% Giemsa stain and observed under light microscope for the frequency of labelled nuclei. It was found that grains start appearing in cultures 20 h after the PHA stimulation, indicating that initiation of DNA synthesis starts after about 20 h of PHA stimulation in normal lymphocyte cultures.

Table 1. ANOVA for per cent (^{3}H) thymidine-labelled cells from cultures of unirradiated and irradiated blood samples of different individuals after varying hours of PHA stimulation. The cultures were set up on the same day of blood collection or after 1 and 3 days of storage.

Source of variation	Degree of freedom	Sum of squares	Mean of square	Variance ratio	Probability <
Individual	1	13.67	13.67	3.31	ns
Irradiation	1	51.86	51.86	12.56	0.005
Hours after PHA stimulation	6	6762.47	1127.08	272.90	0.005
Storage day	2	268.67	134.34	32.53	0.005
Irradiation × hour	6	31.01	5.17	1.25	ns
Storage day × hour	12	201.53	16.79	4.06	ns
Error	41	169.33	4.13		

ns = not significant.

Therefore, in the subsequent experiments, cultures from both unirradiated and irradiated blood samples after 0, 1 and 3 days of storage were given a 30 min (^{3}H) thymidine pulse at 2 h interval in the same way as mentioned above between 18 and 32 h of PHA stimulation. Eight sets of cultures (in duplicate) for 18–32 h post-PHA-stimulation period, for both irradiated and unirradiated conditions for each storage time and each individual were set up (Figure 1). Slides were prepared, processed for autoradiography as mentioned above, and observed for frequency of labelled nuclei. At least 200 nuclei were scored for each point. Percentage of labelled nuclei was statistically analysed using two-way analysis of variance (ANOVA), as it was considered to be the most appropriate method to check the influence of storage duration on the (^{3}H) thymidine incorporation in the unirradiated and irradiated blood samples used from two different individuals.

The ANOVA for (^{3}H) thymidine-labelled cells in both unirradiated and irradiated samples from two different individuals at different hours of pulse treatment is summarized in Table 1. The two individuals did not show any significant difference for the yield of labelled cells (Figure 2). The results showed that the irradiated samples have significantly less frequency of labelled cells compared to unirradiated ones, in relation to storage duration and advancing hours after PHA-stimulation (Figure 2; Table 1). With the increasing storage duration, independent of advancing hours of pulse treatment, a trend of gradual decrease in the frequency of labelled cells compared to fresh blood samples was also noticed in both unirradiated and irradiated conditions (Figure 2). This difference was found to be significant (Table 1).

Using liquid scintillating analysis, it has been shown that (^{3}H) thymidine incorporation into cellular DNA starts only 16–20 h after PHA-stimulation, and the (^{3}H) thymidine incorporation and activity of DNA polymerase increase linearly as a function of time up to 30 h (refs. 9, 10). This is in broad agreement with the

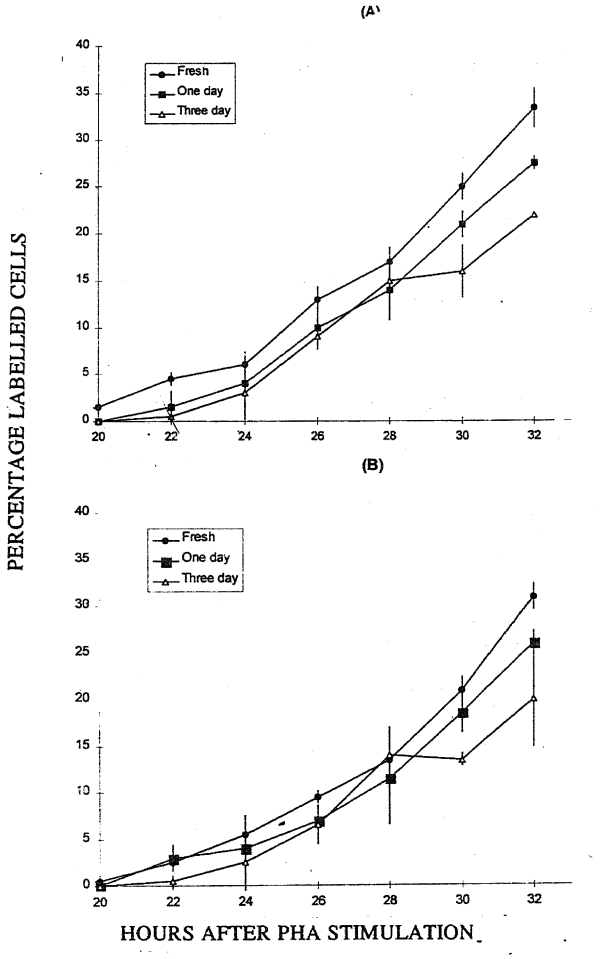

Figure 2. Frequency of (^{3}H) thymidine-labelled lymphocytes in fresh, one day or three day stored unirradiated (*a*) and irradiated (*b*) blood samples after various hours of PHA stimulation.

present autoradiographic study where no significant cellular uptake of (^{3}H) thymidine was observed up to 18 h and then it increased linearly from 20 to 30 h irrespective of storage duration and radiation dose. The pattern for cellular uptake of exogenous deoxyribonucleoside triphosphates (dNTPs) differs in different synchronously or asynchronously dividing cell types and their levels inside the cells are regulated by many factors[11]. Although in the present study, the statistical analysis (ANOVA) did not show any significant inter-individual variation for the frequency of (^{3}H) thymidine-labelled cells, such an inter-individual differences for the response of lymphocytes towards PHA has been a well-documented phenomenon[3]. Significant inter-individual variation for the yield of (^{3}H) thymidine-labelled cells has also been observed when peripheral blood samples from six individuals were labelled between 28 and 34 h following PHA-stimulation[12]. It is therefore likely that independent of the influence of storage condition and radiation treatment, an inter-individual variation would have been observed, if blood samples from more individuals were used in the present study. It will be worth mentioning that in cytogenetic assays using peripheral blood lymphocytes (e.g. micronucleus assay), more variation among the individuals than among repeated experiments on the same individual has been reported[13]. While such inter-individual and flask-to-flask variability for cultured mammalian cells exist, it has been suggested that it has no practical effect on the test outcome[14].

The variability in the (^{3}H) thymidine uptake as a function of storage duration clearly indicates that programmed commitment of cells for the onset of DNA synthesis is altered. This altered commitment for proliferation in turn would influence the cell cycle progression and therefore arrival of the cells at the metaphase stage as observed in our earlier cytogenetic study[6]. A delay in progression from G1 to S, S to G2 or G2 to M phases of the cell cycle may account for an over all effect on cytogenetic dosimetric analysis. In case of X-ray-irradiated lymphocytes, a low dose as 2 cGy has been shown to induce significant variations in cell cycle progression and arrival of the cells at the metaphases[12]. It will be important to mention that there is accumulating evidence indicating that cellular and genetic instability can manifest multiple generations after exposure of cells to agents which either directly or indirectly interact with DNA[15]. It is therefore also possible that the cells might be proportionately delayed in the subsequent cell cycle in the present study. Since the objective of the study was to check whether the appearance of first division metaphases following PHA stimulation as a function of storage is really due to change in the programmed commitment of cells for initiation of proliferation, the cells were fixed at 32 h post-PHA stimulation time. At this time, the first set of metaphases are likely to appear when the cells are processed for chromosomal analysis. With the present experimental approach, it was therefore not possible to verify if there was any delay in the subsequent cell cycle as a function of storage duration.

Since the complexities of cellular growth and division are not precisely clear and products of thousands of genes are required for the normal growth and reproduction of cells[16], it is difficult to assign any specific reason for the delay in cell cycle progression as a function of storage duration. It has been reported that lymphocytes from both pig and human proliferate more slowly in plasma lymphocyte culture than in parallel whole blood culture[17]. Isolated mononuclear leucocytes also exhibit a slower cell cycle progression than whole blood culture[18]. It is well documented that after storage or preservation, changes take place in different components of the blood. These include gradual increase in the osmotic fragility of red blood cells (RBCs), their spontaneous lysis leading to rise in plasma haemoglobin levels besides changes in the nucleotides (including ATP) and phosphorylated carbohydrates[19]. Use of heparin as an

anti-coagulant has also been shown to have no effect on RBC preservation as it lacks dextrose. On storage, its anti-coagulant effect is neutralized by thromboplastic and anti-heparin materials liberated by the cellular elements of the blood[20]. Platelets are considered to be another labile component of blood. It has been suggested that blood stored for more than two days should be considered to be free of viable platelets[21]. The lymphocytes, on the other hand, can be stored as long as four days at room temperature for immunological sub-population analysis[22,23]. These lymphocytes in the absence of optimum blood components like erythrocytes and platelets may progress slowly after PHA-stimulation in culture as observed in plasma lymphocyte or isolated mononuclear leucocyte culture[17,18]. In fact, it has been shown that when rat RBCs are added to purified rat leucocyte cultures, the cell cycle progression is considerably faster. It has been suggested that lymphocytes are released from inhibition to growth and proliferation by the presence of RBCs[24]. In this context, it will be also important to mention that mitogen-stimulated lymphocytes are particularly susceptible to undergo the phenomenon of apoptosis (programmed cell death) either under stressful culture conditions such as serum deprivation or after the induction of damage to cellular DNA[25]. Since storage condition leads to change in the biochemical and physiological properties of the different components of the blood, it is likely that under such stressful condition, the lymphocytes may undergo the phenomenon of apoptosis, resulting into reduced frequency of labelled cells. Parallel to this, the irradiated cells would have probability to undergo DNA damage-induced apoptosis and would show a further reduction in the frequency of (^{3}H) thymidine-labelled cells.

In conclusion, the storage of peripheral blood samples at room temperature delays the cell cycle progression and may impart additional source of variability when used for experimental purposes. It would be important to understand how the interaction of component cells of blood influences the rate of proliferation and the duration of the cell cycle. It would be also interesting to precisely identify different storage labile factors and then by manipulating them, prevent or modify the proliferative response. Such factors, besides other components of the blood may include sub-cellular metabolites, cytosolic and membrane-bound receptors and enzymes.

^{207}Pb/^{206}Pb ages of zircons from the Older Metamorphic Group (OMG), the oldest recognized rock unit from the Singhbhum–Orissa Iron Ore Craton, eastern India, have been determined by ion microprobe.

The zircon ages lie between 3628 and 3196 Ma and cluster around 3.55, 3.4 and 3.2 Ga. The zircons belonging to the first age group occur mostly as subrounded cores or as well rounded to subhedral grains of apparent detrital origin, while the zircons belonging to the younger groups occur as subhedral, prismatic grains or as overgrowths. Our data suggest that the provenance of the sedimentary precursor included granitoid rocks with ages between 3.6 and 3.5 Ga, confirming the presence of Early Archaean crust in the Singhbhum region. The younger age of 3.2 Ga most probably reflects a later metamorphic event which overprinted the OMG rocks. Finally, our data establish an older limit of ~3.5 Ga for the age of sediment deposition.

THE Singhbhum–Orissa Iron Ore Craton of eastern India is a triangular crustal block of Precambrian age covering an area of about 40,000 km^2. The province contains an almost-continuous geological record from the Archaean to the Mid-Proterozoic[1]. The oldest rocks of sedimentary origin recognized in this craton are designated the Older Metamorphic Group (OMG), which include amphibolite facies pelitic schists, arenites, calc-arenites, calc-schists and ortho- and para-amphibolites[1]. The type area of the OMG is around Champua (Figure 1) where it is exposed over an area of about 200 km^2 to the west and southwest of the Champua town. Here the rocks are intruded by biotite–hornblende tonalite and granodiorite gneisses designated the Older Metamorphic Tonalite Group (OMTG). Rock types similar to the OMG (mainly amphibolite grade) also occur as enclaves of varying dimensions throughout the Singhbhum granite batholith[1].

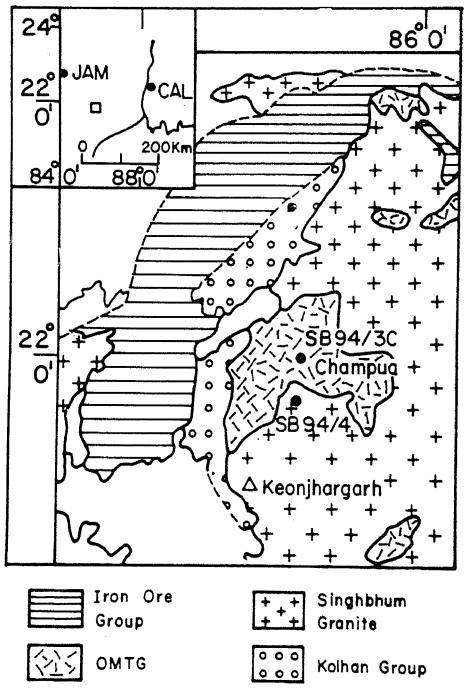

Figure 1. Geological map (after Saha[1]) of the Singhbhum–Orissa Iron Ore Craton around Champua showing the sample locations. The rectangle in the inset indicates the approximate geographical location of the area (JAM – Jamshedpur; CAL – Calcutta).

Geochronologic data from the OMG suite of rocks is restricted to K–Ar and Ar–Ar mineral ages[2,3]. These ages fall in the range of 3.4 to 3.1 Ga and are interpreted as metamorphic ages (see e.g., Saha[1]). This implies that OMG sedimentation took place at or before 3.4 Ga. In this paper we present the results from our ion microprobe study of $^{207}Pb/^{206}Pb$ ages of single zircon grains separated from the OMG metasediments. Our main emphasis is to obtain an age spectrum for the detrital zircon component in the metasediments – the youngest detrital component will provide an older limit for the age of sedimentation. We have considered morphological signatures (e.g. well rounded to subrounded shape with low length to width ratio, resulting from abrasion during sediment transport) to identify zircons of detrital origin (see Figure 2). We have also analysed morphologic overgrowths on single grains, in order to establish the age of metamorphism which has overprinted the OMG.

Two samples of the OMG metasediments were collected for the present study from the type area near Champua (Figure 1). The first sample (SB-94/3C) was collected from a hillock 2 km west of the Champua inspection bungalow. Here the OMG metasediments consist of a sequence of brownish-red muscovite–biotite schists grading to very pure orthoquartzite. The present sample is a quartz-rich member from this sequence. The second sample (SB-94/4) was collected about 15 km away from a site 4 km north of Ramuli village close to the main road connecting Champua to Keonjhargarh. It is an orthoquartzite with mica-rich bands. Although both samples belong to the OMG group, their exact stratigraphic relationship is difficult to establish in the field.

The samples were processed using standard techniques to obtain zircon grains. They were crushed into cm-sized chips and these chips were washed, care being taken to eliminate any material which showed weathered portions. The chips obtained from each sample were then dried in air and were further crushed to < 250 μm using a stainless steel piston and cylinder. The fractions were then washed to remove the fine dust produced during crushing and were dried in air at 60°C. Zircons were concentrated from the washed fraction using an aqueous Na-polytungstate solution (density = 3 g/cc) followed by magnetic separation. Finally, individual zircons were hand-picked using a binocular microscope. The clear and least intensely coloured zircons were mounted on double-sided tape, cast in epoxy and sectioned by polishing. The better grains (based on transparency and simplicity of internal structures) were documented in detail. The grain mounts were thoroughly

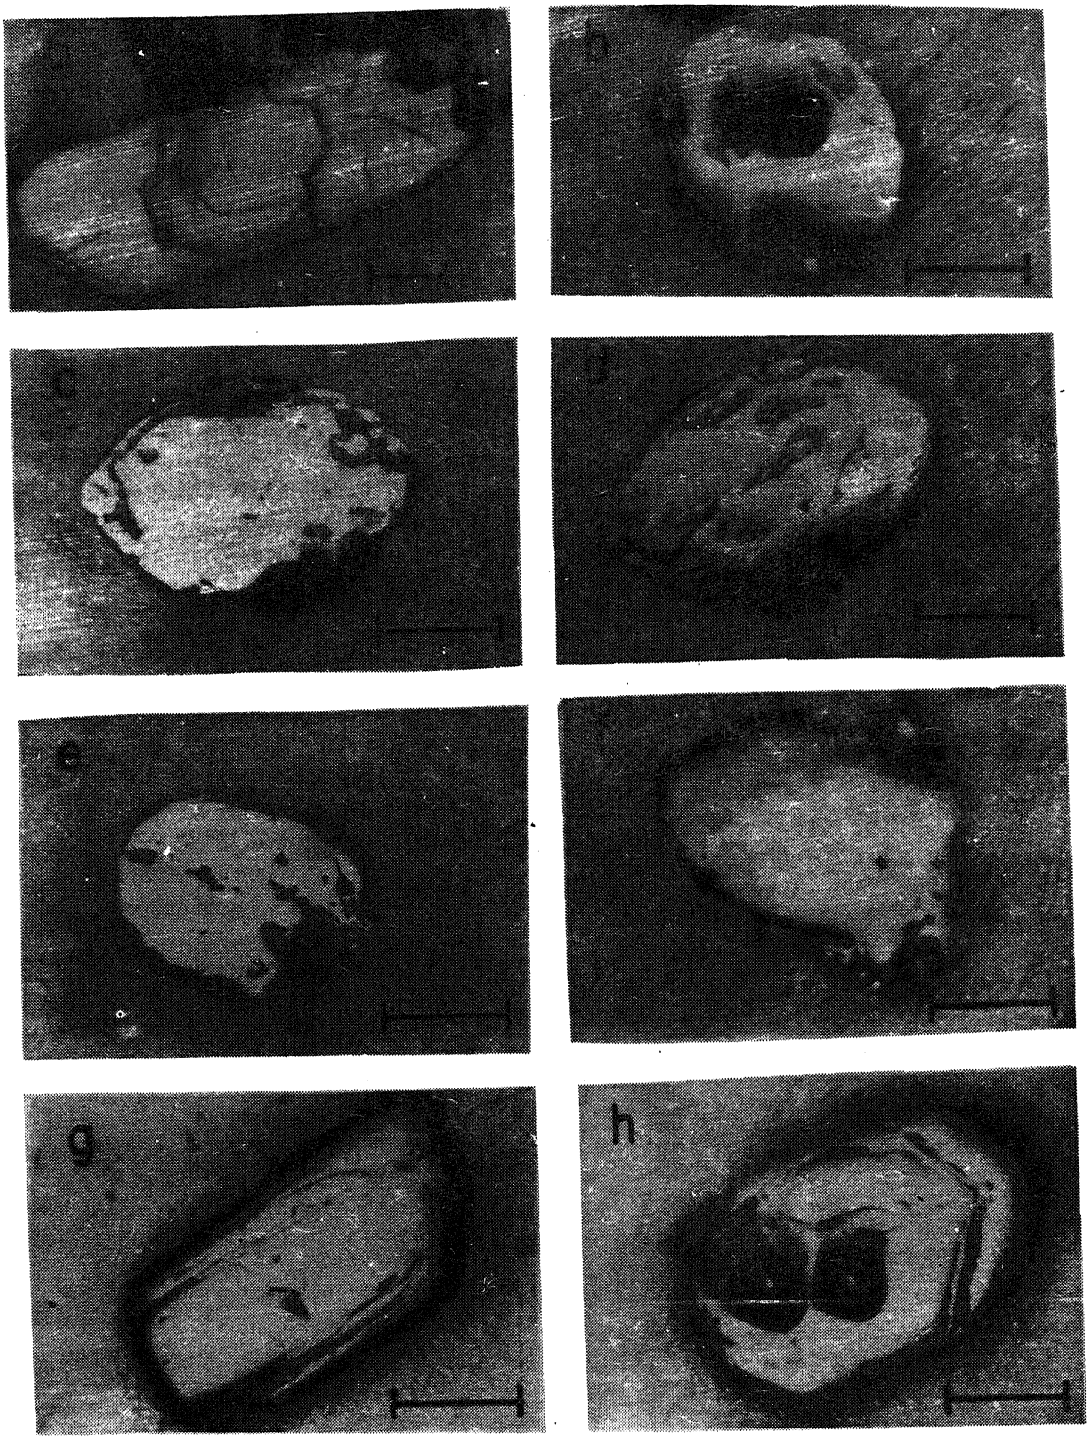

Figure 2. Reflected light photomicrographs of zircon grains recovered from the OMG metasediments. Sputter holes caused by the primary ion beam during Pb-isotopic analyses can be seen in a couple of grains (*b* and *h*). Zircons shown in Figure 2 *a* – *e* belong to the >3.5 Ga group. Scale bar is 50 μm in each case.

cleaned in ethanol using an ultrasonic bath prior to deposition of a 100 nm thick, high-purity gold coat needed for isotopic measurement using the ion microprobe.

Very few good zircons could be extracted from the orthoquartzite (SB-94/3C). The recovered grains are subhedral, prismatic, transparent and appear colourless to brownish in transmitted light. Both homogeneous grains and grains with distinct core-overgrowth morphologies are present. We could recover several good zircons from the sample of the quartzite (SB-94/4). In morphology they are generally homogeneous, though a

small fraction have extremely well rounded grain morphologies. These zircons contain both apatite and some unidentified brown prismatic minerals as rare inclusions.

We used a Cameca ims-4f ion microprobe for Pb-isotopic analysis using procedures described earlier[4]. We operate the instrument at high mass resolution (M/ΔM~4600) to resolve all the significant isobaric molecular interferences on the Pb isotope mass spectrum. A 7 nA focused primary beam of $^{16}O^-$ was used to analyse Pb-isotopic composition of ~20 μm domains within individual zircon grains. A single analysis consisted of 15 blocks of data; each block comprised of 5 scans through the mass sequence $^{204}(Zr_2O)$, ^{204}Pb, ^{206}Pb, ^{207}Pb, $^{208}(HfO_2)$ and ^{208}Pb in peak jumping mode. The age of each analysis is based on the weighted mean radiogenic $^{207}Pb/^{206}Pb$ ratio obtained from the data of the 15 quasi-independent blocks. In the absence of U–Pb data, we lack detailed information on the Pb-loss history of the analysed samples. We have, therefore, developed objective criteria to identify Pb-loss as well as multiple age components within our data set. The details of the procedure adopted by us for data acquisition and assessment are reported elsewhere[4–6].

We conducted 10 analyses on three zircon grains from the ortho-quartzite sample SB-94/3C. In three of these analyses the common Pb component was high (as evident from high $^{204}Pb/^{206}Pb$ ratios); these analyses were excluded from the data set (Table 1), thus eliminating those analyses which show obvious evidence for Pb-exchange with the extra-crystalline environment. An unique zircon (grain number 1) recovered from this sample has a distinct subrounded core with a distinct euhedral overgrowth (Figure 2*a*). Three analyses carried out in the core region of this grain (analysis numbers 1A–C) yielded ages ranging between 3591 and 3525 Ma with a mean value of 3551 ± 13 Ma (errors quoted here and rest of the text are 1σ). Two analyses of the overgrowth (numbers 1D, E) yielded a distinctly younger mean age of 3232 ± 12 Ma. Another prismatic zircon having a narrow overgrowth at one end (Figure 2*h*) yielded an age of 3286 ± 22 Ma for its central region. The interior of a third elongated zircon possessing multiple growth zones (Figure 2*g*) has an age of 3378 ± 34 Ma.

Results from 13 analyses conducted on eight zircon grains from the quartzite sample SB-94/4 are also given in Table 1. As in the previous case, the analyses having high $^{204}Pb/^{206}Pb$ ratio are excluded from this data set. One of the zircons analysed from this sample (grain number 7) has an extremely well rounded grain mor-

phology (Figure 2 *b*). Two analyses conducted on this grain (numbers 7A, B) yielded ages of 3583 ± 25 and 3505 ± 30 Ma respectively. Two more zircons – a prismatic grain and the core region of a sub-rounded grain (numbers 2 and 13; see Figures 2 *c*, *d*) – have ages of 3538 (mean of analysis numbers 2A, B) and 3628 Ma respectively (Table 1). Two analyses carried out on either side of a longitudinal fracture in another homogeneous, rounded zircon (grain number 3; Figure 2 *e*) yielded ages of 3501 and 3323 Ma respectively; we suspect that one or both of these ages reflect partial Pb-loss from a single domain which crystallized at or before 3501 Ma. Four analyses conducted on three homogeneous zircons (grain numbers 4, 11 and 12) from this sample (e.g., Figure 2 *f*; grain number 11) yielded intermediate ages around 3.4 Ga. Another homogeneous zircon (grain number 1) from this sample has a distinctly lower mean age of 3223 Ma (analysis number 1A, B). We have also estimated the U content of the zircons based on a close system approximation; these values range from a few tens of ppm to a few hundred ppm (Table 1).

The data shown in Table 1 reveal three groupings: greater than 3.5 Ga, 3.43–3.38 Ga and ~3.2 Ga for the analysed zircons. The age of 3.2 Ga for the overgrowth around the 3.55 Ga old detrital core (SB-94/3C, analysis numbers 1A–F) strongly suggests that the 3.2 Ga age reflects a younger metamorphic event affecting the OMG rocks that led to the growth of zircon on an older core. The morphology of this overgrowth (Figure 2 *a*) does not support a detrital origin for the total core-overgrowth assemblage. We note that the 3.2 Ga signature is seen in zircon grains analysed from both the samples.

Two of the zircons belonging to the >3.5 Ga group are clearly of detrital origin as attested to by their sub-rounded shape (Figures 2 *a*, *b*). Among the other three zircons belonging to this age group, two show distinct evidence of rounding of edges with low length/width ratios (Figures 2 *d*,*e*), while the third one possesses an ambiguous morphology (Figure 2 *c*). We, therefore, conclude that crust of ~3.6 to 3.5 Ga age was a major sialic component within the provenance of the OMG.

The four zircons with ages between 3.38 and 3.43 Ga are all homogeneous, subhedral, prismatic grains and do not show obvious detrital characteristics. Unfortunately, the lack of detailed information on possible Pb-loss history of these grains makes it difficult to attribute these ages to specific geologic events. We note that the lower end of this range is only slightly older than a recently reported Sm–Nd age of 3305 ± 60 Ma (2σ) for the OMG amphibolites[7].

The present study provides several important geochronological constraints on the evolution of the Singhbhum Craton. The zircon ages from the OMG metasediments confirm the presence of an Early Archaean crust in this region. Our data suggest that the provenance of the sedimentary precursor contains a significant granitoid component with ages ~3.6–3.5 Ga. Zircon growth, possibly in response to a regional metamorphic overprinting, has been identified at ~3.2 Ga. Our results also provide an older limit of ~3.5 Ga for the age of sediment deposition.

Significance of the terminal Cretaceous calcareous nannofossil marker *Micula prinsii* at the Cretaceous–Tertiary boundary in the Um Sohryngkew section, Meghalaya, India

Rahul Garg and K. P. Jain

Birbal Sahni Institute of Palaeobotany, 53, University Road, Lucknow 226 007, India

A diagnostic calcareous nannofossil assemblage, representing the terminal Maastrichtian *Micula prinsii* zone, is discovered below the iridium-spike bearing clay-layer in the Um Sohryngkew section, Meghalaya. Its significance for the precise demarcation of the K/T boundary, providing crucial evidence for the presence of the youngest Cretaceous sediments in a continuous, bioturbation-free calcareous shale sequence, is demonstrated.

THE Um Sohryngkew section is located on the western bank of the Um Sohryngkew river, about 1 km northeastwards of the Therria village in the foothills of the Cherrapunji Plateau, Meghalaya, northeastern India

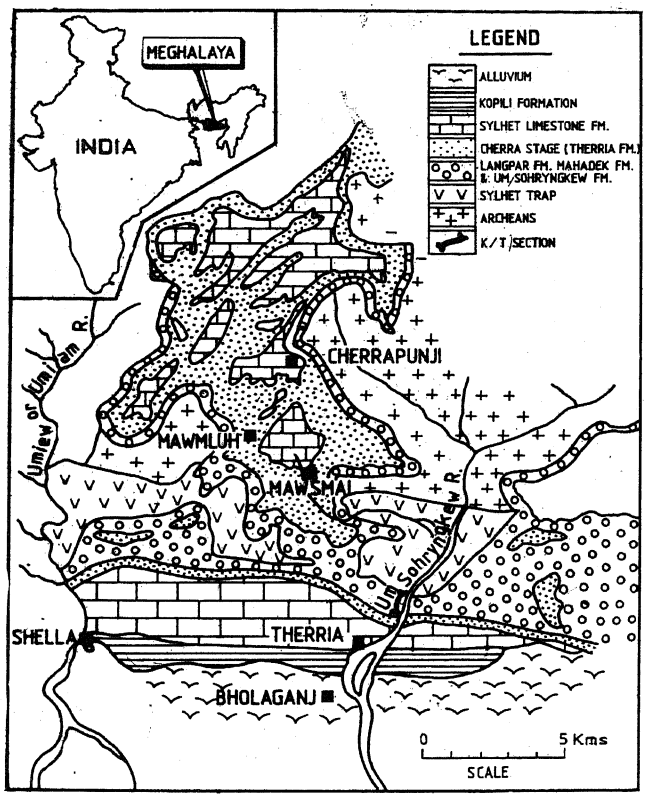

Figure 1. Geological map of the Cherrapunji area, Meghalaya, showing the location of the K/T boundary section (Redrawn after Ghosh, A. M. N., 1940). The 'Cretaceous beds' mapped by Ghosh now include the Um Sohryngkew, Mahadeo and Langpar formations of the Late Crataceous–Paleocene age.

(Figure 1). Cretaceous–Tertiary boundary in this section has been demarcated on the planktonic foraminiferal evidence[1,2]; the top of Maastrichtian has been marked by the abrupt disappearance of a rich *Globotruncana–Heterohelix* suite, while the basal Palaeocene is distinguished by the residual Cretaceous planktonics dominated by *Guembelitria cretacea* (PO Zone) at the base, followed stratigraphically higher by the appearance of a typical Danian *Turborotalia eugubina–T. sabina* assemblage Zone[3]. Geochemical studies across this interval subsequently revealed a significant enrichment of iridium and other siderophyle elements in a 1.5 cm thick clay layer[4,5], coinciding with a major depletion of Cretaceous planktonic foraminifera. Contrary to this, Lahiri *et al.*[6] opined that 'no such widespread break' in planktonic foraminifera at the K/T iridium layer is noticeable, as a Late Maastrichtian assemblage continues stratigraphically higher, suggesting the placement of the boundary about 30 m above this layer. However, these observations have recently been discussed and rejected[7]. Our recent discovery of a rich suite of Danian dinoflagellate cysts and calcareous nannofossils along with the Early Tertiary nautiloid *Hercoglossa kutchensis* Tandon and Srivastava 1980 (Figures 2 *A–C*) below the K/T boundary level suggested by Lahiri *et al.*, also disproves their contention. Jafar and Singh[8] considered the Um Sohryngkew section to be an incomplete K/T boundary sequence due to the absence of the latest Maastrichtian planktonic foraminifer marker *Abathomphalus mayaroensis* and the calcareous nannofossil *Micula prinsii*, and the reported continuation of bored Cretaceous planktonic foraminifera above the iridium layer. They further substantiated this inference by simply considering reports of the presence of the basal Danian planktonic foraminifer markers *Globigerina fringa* and *G. eugubina*[3] to be 'poor' and 'dubious' without providing any substantial arguments.

Thus, the recording of a characteristic latest Maastrichtian calcareous nannofossil assemblage, belonging to the *Micula prinsii* zone, from immediately below the iridium-rich clay layer, confirms not only the existence of the youngest Maastrichtian in this section but also suggests demarcation of K/T boundary below this layer[9,10].

The material for the present study was initially collected during a field trip in February 1987 (in which Jagadish Pandey[3], S. K. Acharyya and M. K. Sen[6] also participated), and subsequently in February 1990, when more closely spaced samples at 5 cm intervals (sample thickness ca. 2–2.5 cm) were collected from a nearly 2 m interval across the clay layer. The studied part of the K/T succession consists of non-bioturbated, thinly laminated calcareous to fine silty shales which are dark grey to ash grey in lower part, followed by a 1.5 cm thick reddish-brown clay layer, overlain by greyish to yellowish-brown calcareous fine silty shales.

These calcareous shales have lately been included within the Mahadeo Formation[1,2]. However, the authors prefer to group these beds within the overlying Langpar Formation, in accordance with the original lithological criteria[11–13]. The Langpar Formation, comprising calcareous shale, carbonaceous shale and argillaceous limestone, conformably overlies the Mahadeo Formation, consisting of glauconitic non-calcareous sandstone and sandy shale, becoming calcareous in the upper part. There is a distinct gradational transition from a greenish-grey, sandstone-shale facies of the Mahadeo Formation into the overlying dark to light grey, calcareous shale-limestone facies of the Langpar Formation. The sequence studied immediately overlies these passage beds.

Abundant and diversified Late Cretaceous calcareous nannofossil assemblages have been recovered from samples underlying the iridium-rich clay layer. They contain the terminal Maastrichtian, low latitude zonal marker *Micula prinsii* Perch-Nielsen 1979 along with *M. murus* (Martini) Bukry 1973. *M. decussata* and *Watznaueria barnesae* are the most abundant and consistent species in the studied interval (Figure 3). This assemblage typically represents the *Micula prinsii* zone of the latest Maastrichtian.

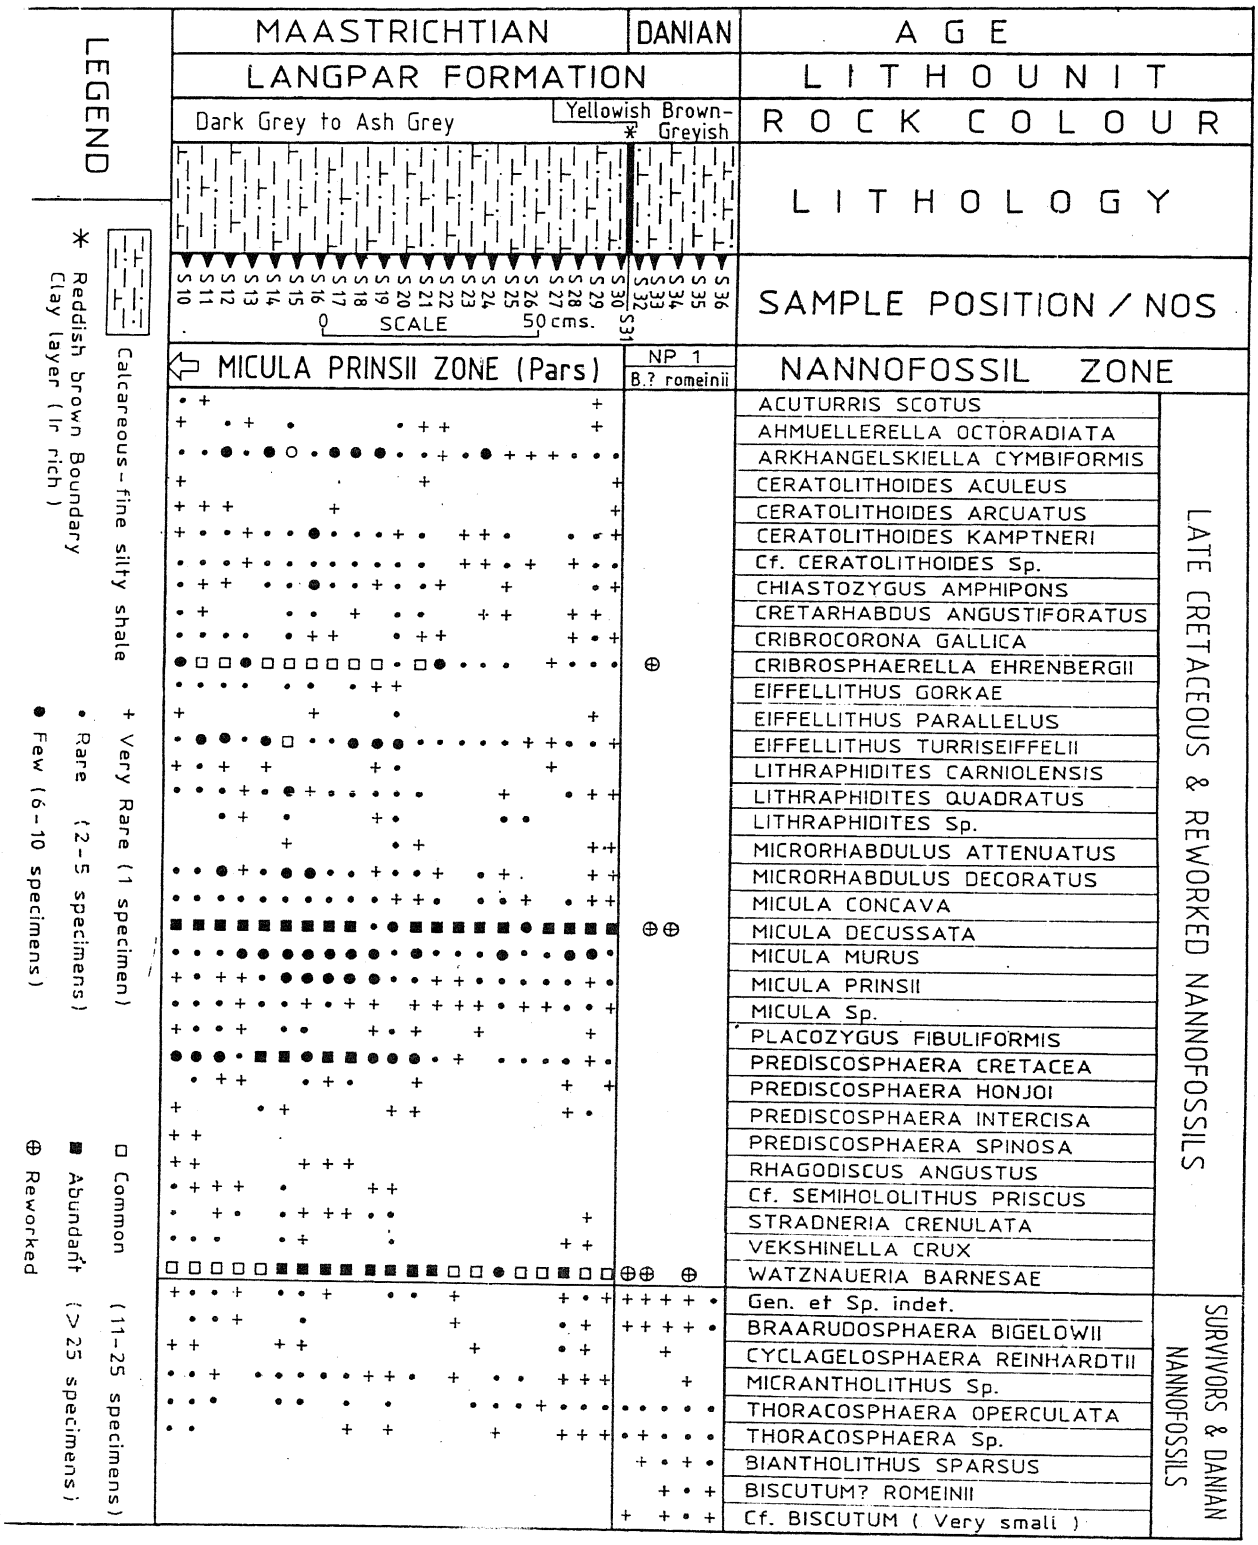

Figure 3. Distribution of Late Maastrichtian calcareous nannofossil species in the Um Sohryngkew section.

The *Micula prinsii* zone was established for the uppermost Maastrichtian[14,15] and can be correlated to the top of the *Micula murus* zone of Thierstein[16] and the *Nephrolithus frequens* (CC26) zone of Sissingh[17]. *M. prinsii*, which evolved from *M. murus*, has its FAD after the first appearance of both *Nephrolithus frequens* and the planktonic foraminifer marker *Abathomphalus mayaroensis*[14,18,19]. It is the most significant species to document the presence of the youngest Cretaceous sequence especially in low and mid latitudes[20,21], e.g. El Kef (Tunisia), Lattengebirge (Germany), Biarritz (France), DSDP site 534 (S. Atlantic)[20]; Barranco del Gredero near Caravaca (Spain)[22] and Hor Harar (Israel)[23].

In Um Sohryngkew section, the rich Maastrichtian nannofossil assemblage abruptly disappears above sample no. S-30 (Figure 3). Nannofossils have not been observed in the iridium-rich clay layer (sample S-31). In the immediately overlying calcareous to fine silty shales, the nannofossil assemblage is greatly reduced containing only rare *Thoracosphaera operculata, Thoracosphaera* sp., *Braarudosphaera bigelowii* and extremely rare *Cyclagelosphaera reinhardtii* and *Micrantholithus* sp. These 'survivor' species belong to a suite of calcareous nannofossils which are believed to have survived the K/T boundary biotic crisis and extend from the Maastrichtian into the basal Danian[20]. Brightly birefringent elliptical to broad elliptical coccoliths (2–5 μm) are found to occur across the K/T boundary, without any appreciable change in size. Rare occurrence of this form is recorded in the Upper Maastrichtian as well as in the basal Danian where it is found to occur consistently in the studied interval. In our opinion, records of this species above the K/T boundary are not due to reworking but seem to represent genuine occurrences. It is documented here as Gen. et sp. indet. and is listed under 'survivor' species for the present (Figure 3).

It is generally believed that a 'continuous' marine K/T boundary section in low latitudes should include the uppermost Cretaceous coccolith zone of *Micula prinsii* followed by the boundary clay within the planktonic foraminiferal zone of *Globigerina fringa*, followed by *G. eugubina*, in the basal Danian[20]. However, the occurrence of a relict survivor Late Cretaceous planktonic foraminiferal faunule belonging to the *Guembelitria cretacea* zone [PO], in the earliest Danian below the *G. fringa* zone is now recognized to be extremely significant in establishing the continuity of a complete K/T boundary sequence[24–27].

The argument of Jafar and Singh[8], that the reported 'continuation' of a relict Cretaceous planktonic foraminiferal assemblage, representing the *G. cretacea* zone, above the iridium-rich layer in the Um Sohryngkew section[3] is abnormal for a complete K/T boundary sequence, is, thus, not valid. Further, the 'absence' of *Micula prinsii* in several Indian sections, including Meghalaya and Andaman Islands postulated by them[8] should be viewed with caution. *M. prinsii* has previously been listed in a 'nannoplankton cocktail' obtained from a solitary mud-volcano sample from Baratnag Island that yielded a mixed assemblage of Campanian–Danian age[28]. However, *M. prinsii* could not be recovered in subsequent studies of mud-volcanoes of the same region[29], thus rendering its earlier report from Andaman Islands to be questionable[30].

According to Pandey[2], the zonal planktonic foraminifer marker, *A. mayaroensis*, is absent in Meghalaya. He consequently instituted the *Globotruncana staurtiformis* zone as a substitute for the Maastrichtian *A. mayaroensis* zone. Jafar and Singh[8] misquoted Bhandari *et al.*[4] by crediting them with noting the occurrence of *A. mayaroensis* in eastern Indian sections, including Meghalaya, but at the same time suggested that this species 'may in fact be missing altogether' from this region. *A. mayaroensis* has been recorded from the Cauvery Basin[31], the Krishna–Godavari Basin[32,33], the Andaman Islands[34,35] and exotic limestone in the Ukhrul Melange Zone of the Nagaland–Manipur Ophiolite belt[36]. Occurrence of a well-preserved and complete assemblage containing *A. mayaroensis* has also been reported from DSDP Site 217 in the Bengal Abyssal plain in the Indian Ocean[37].

In view of the absence of this zonal marker in the Um Sohryngkew section, correlation with the *A. mayaroensis* zone has been suggested based on the occurrence of a rich planktonic foraminiferal suite containing *Globotruncana stuarti, Rugoglobigerina rotundata* and *R. scottii*[2]. However, these taxa do not provide unequivocal evidence for the presence of the youngest Maastrichtian in the section, as none of these is restricted to *A. mayaroensis* zone. Moreover, *A. mayaroensis* is not considered to be a reliable taxon for identifying the K/T boundary, especially in the shallow continental shelf sections as it is geographically and ecologically restricted[27,38]. An alternative biozone, *Pseudotextularia deformis* was proposed for shallow continental shelf sections[26].

We, therefore, conclude that the present discovery of rich calcareous nannofossil assemblages from the *Micula prinsii* zone immediately below the iridium-rich clay layer illustrates the definite presence of terminal Maastrichtian sediments in this section. It apparently substantiates the planktonic foraminiferal record to fulfil the criteria for a biostratigraphically complete and continuous shallow marine KTB sequence. The continuity of the section is also suggested by the occurrence of bioturbation-free calcareous shales, albeit with a modest colour change, across the 1.5 cm thick iridium-rich clay layer which marks the K/T boundary.

A phosphorite crust was found at 380–390 cm depth interval of a sediment core collected from the topographic high occurring on the continental slope off Goa. This crust is fragile and grey to light brown in colour. Carbonate fluorapatite is the predominant mineral followed by minor pyrite. Thin section studies indicate that it is mostly homogeneous with a few bone fragments and shows porous microstructure. SEM studies show that it contains agglomerated 1–2 μm size apatite globules resembling phosphatized bacteria and coalesced bacteria. Microprobe geochemistry of the phosphorite indicates that it contains 33% P_2O_5 and 50% CaO with other major elements (Si, Al, Ti, Fe, Mg, Na and K) amounting to only 1.8%. The mode of the phosphorite crust formation is discussed in relation to Quaternary phosphorites in upwelling and non-upwelling regions. It is suggested that the initial substrate for the phosphorite crust was most probably a fish coprolite which phosphatized under lower rates of terrigenous sedimentation and calm environmental conditions during the Pleistocene.

IN phosphorites the P_2O_5 content generally exceeds 18% and it may sometimes reach up to 40%. Phosphorites with higher P_2O_5 content are not only of scientific interest but are also of significant economic value. So far, phosphatized limestones consisting of 2–14% P_2O_5 (bulk analyses)[1–5], the sediments[6] with 0.2–2.0% P_2O_5 and glaucony-phosphate facies associated sediments[7] were reported from the western continental margin of India. In this paper, we report the origin and significance of high-grade phosphorites (34% P_2O_5) sporadically occurring at subsurface depths of the sediment cores collected from the topographic high on the continental slope off Goa.

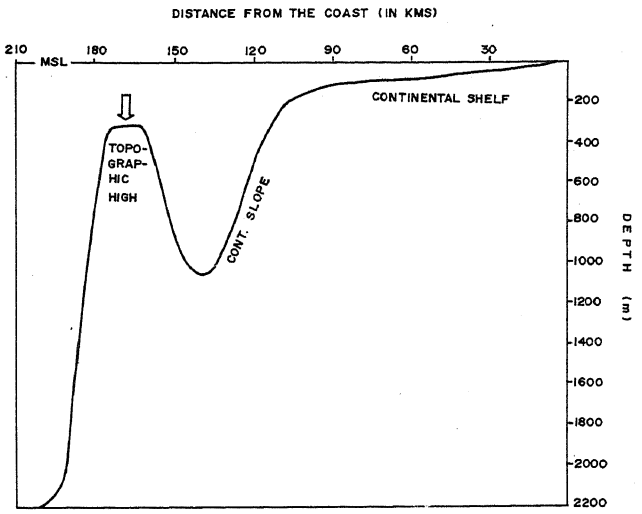

Figure 1. Schematic cross section of the continental margin off Goa showing topographic high on the continental slope; arrow shows the core location (data provided by Dr M. Veerayya).

As a part of Institute's geological exploration programme, more than 30 sediment gravity cores were collected on the western continental margin of India (in the year 1993–94) during different cruises of *O R V Sagar Kanya* and *A A Siderenko*. Most of these cores are from the central and southwestern margin where intense seasonal upwelling has been reported. These cores are distributed at water depths between 20 m and 2000 m and thus are located above, within, and below the oxygen minimum zone (150–1500 m). During subsampling the sediment cores onboard, phosphorite nodules/crusts were found only in three gravity cores collected from the topographic highs occurring on the continental slope off Goa (Figure 1). These phosphorites occur sporadically at one or two sediment intervals at deeper subsurface depths of the cores. All these phosphorites contain about 34% P_2O_5. In the remaining cores there are no phosphorites except a few phosphate grains occurring as traces at different sediment intervals.

The phosphorite crust studied here is from a 4.3 m long gravity core (GC-2) collected on the topographic high in 330 m water depth off Goa (Figure 1) (14°49.6′N, 72°38.8′E) during the VI cruise of *A A Siderenko*. This crust is found at 380–390 cm depth interval of the core. The phosphorite crust is about 3.5 cm long and somewhat flat with thickness of about 1.5 cm (Figure 2 *a*). It is grey on one side and light brown on the other. It is friable and similar to F (friable)-phosphates reported by Garrison and Kastner[8]. Both the surfaces show grooves (Figure 2 *a*) and small boring cavities, indicating that it was indurated under hardground conditions. Bulk mineralogy by X-ray diffraction (Figure 3) shows that the carbonate fluorapatite is the only mineral phase. Pyrite, however, occurs in acid insoluble residue. The bulk chemistry analysed by ICP-AES shows that the crust consists of about 34% P_2O_5 and 49% CaO. The major element geochemistry of the phosphorite, analysed by microprobe, significantly differs from that of the Modern/Quaternary phosphorite nodules/crusts in other upwelling/non-upwelling regions (see Table 1) and consists of more P and Ca and very low content of other major elements. Bone fragments contain relatively less P_2O_5 than the matrix (Table 1).

Thin section of the phosphorite indicates that it is mostly homogeneous with a few scattered bone fragments and fish remains and shows porous structure (Figures 2 *b*, *c*). Pyrite occurs as small black grains. The bones are susceptible to degradative transformation and show different stages of phosphomicritization (Figures 2 *d*, *e*). Some bones are partly micritized (Figure 2 *e*) and others are completely micritized and transformed into undifferentiated peloids (Figure 2 *f*). Elsewhere, the bones are surrounded by black material of possible organic origin. SEM observations on freshly broken surfaces of the phosphorite attest the thin section findings. It consists of abundant porous microstructure with adjacent moderately compacted areas (Figure 4 *a*). Within the porous area, apatite everywhere occurs as agglomerated globules of different size (0.5–2 μm) (Figure 4 *b*). These globules resemble phosphatized bacteria and coalesced bacterial structures[9,10]. The compact areas seem to correspond to thick coalescence of globules and globule aggregates. Figure 4 *c* shows the pyrite aggregate composed of many cubes and octoids of pyrite and porous apatite structure corresponding to globules.

The sediments of the core are clayey at the surface and up to 40 cm depth of the core and clayey sand/silty sands occur below. The organic carbon content in the upper 40 cm of the core is high (about 8%) and in the remaining core, it ranges from 0.8 to 3.7%, with an average value of 1.0%. In contrast, the calcium carbonate content is low (up to 43%) in the upper 40 cm and increases down core with values ranging from 60 to 80%. Coarse fraction studies indicate that in the upper part of the core, planktonic foraminifers show solution features and contain several keels of planktonic foraminifers and pyrite encrusted/infilled foraminifers. In the remaining part of the core, the coarse fraction consists of abundant planktonic forams, pteropods, shell fragments, molluscs and otoliths distributed more or less uniformly in the core. Corals encrusted on a small gastropod shell (Figure 5) were found at a sediment interval 360–370 cm), close to that of phophorite depth interval (380–390 cm).

Some of the Modern phosphorites (off Peru and SW Africa) occur in upwelling regions[11,12], while others (Eastern Australia phosphorites) are in weak/non-upwelling regions[13]. As the western margin of India is concerned, (a) intense seasonal upwelling occurs on the southwestern continental margin of India, (b) organic carbon values range from 3–16% in the surficial sediments of the continental slope[14] and up to 8% in the

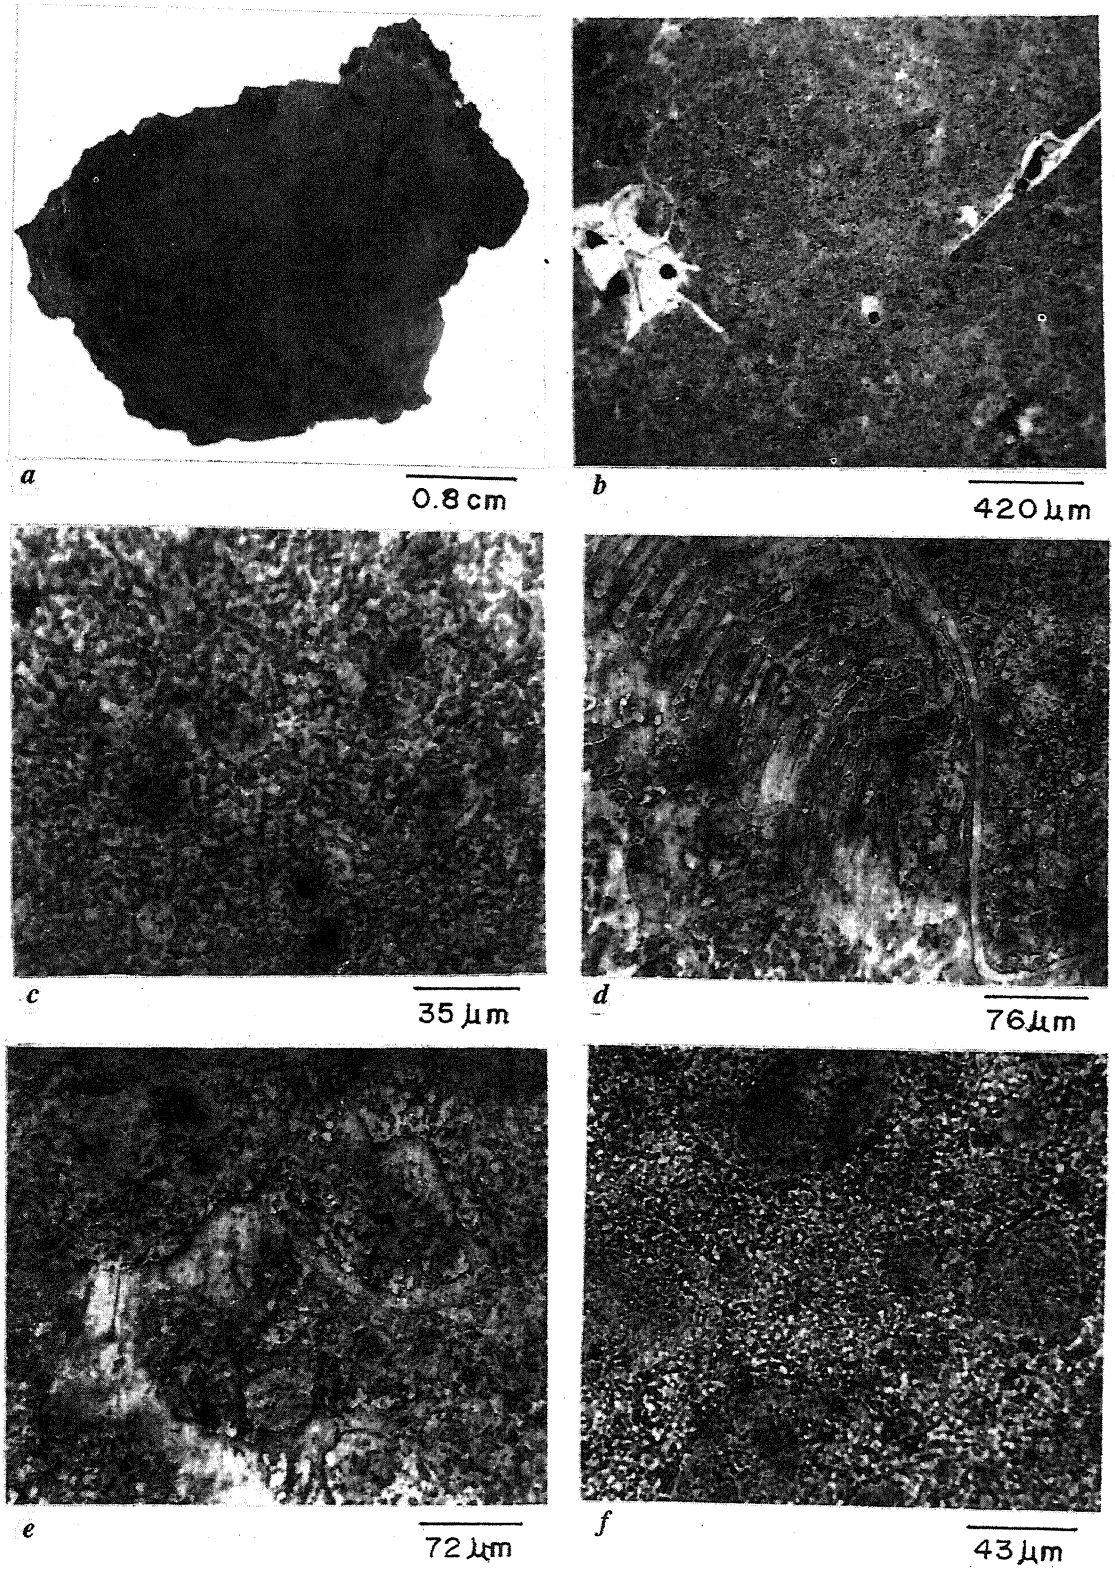

Figure 2. *a*, Phosphorite crust; (*b–f*) are thin section photomicrographs; *b*, at low magnification showing homogeneous apatite structure with a few bone fragments; *c*, high magnification showing porous microstructure; *d*, fish bones being micritized; *e*, bone fragment showing phosphomicritization; *f*, the end product of phosphatization of bones showing undifferentiated phosphate peloids.

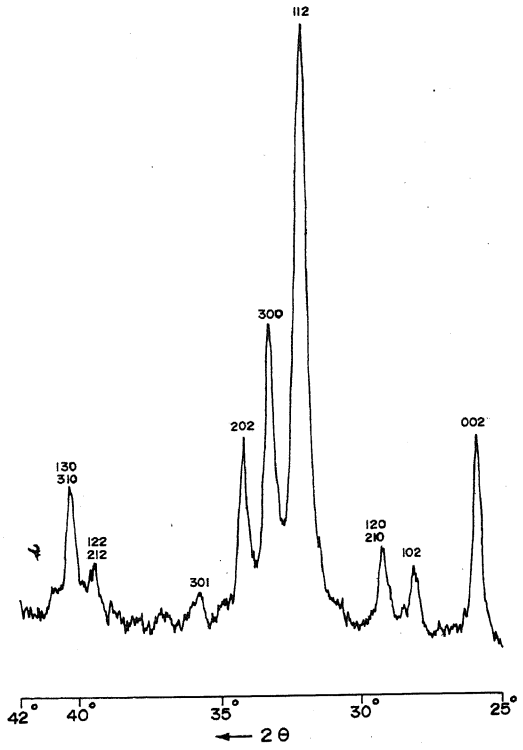

Figure 3. X-ray diffractogram of the phosphorite (bulk analysis), showing all the reflections are due to carbonate fluorapatite.

upper 1 m sediments of the gravity cores (M. Thamban, unpublished work) and are comparable to the organic carbon values of the Peru and SW African margins and (c) oxygen minimum zone (150–1500 m) intersects the continental slope. In spite of all ((a)–(c)) these upwelling-induced conditions, phosphorites have not been observed in the upper one meter sediments of all the thirty gravity cores. We, therefore, suggest that just having upwelling is not sufficient enough to produce phosphorites. Glenn *et al.*[15] recently reviewed the environmental conditions for phosphorite formation and suggested the influence of several factors on phosphogenesis. As the sediments in the cores are carbonate-rich, carbonate ion concentrations in the pore waters[16] and rate of sedimentation are probably major controlling and inhibiting factors for the formation of modern phosphorite in this margin.

Modern/Quaternary phosphorites mostly occur in the form of nodules/crusts. The initial substrate (host) for phosphorite is part of sediment and obviously the phosphorite nodule/crust is heterogeneous and contains partly replaced and/or unaltered sediment constituents such as diatoms, foraminifers, quartz, clay minerals, etc. The geochemistry of this type of diagenetic nodules/crusts is shown by higher contents of other major elements along with higher P values (see Table 1) supporting the existence of sediment constituents. Although the calcareous skeletal dominated sediments are associated with the phosphorite under investigation, it neither contains carbonate skeletals nor other sediment constituents except bone fragments (Figure 2). Geochemistry also shows higher P and Ca values and very low content of other major elements than the modern phosphorite nodules/crusts (see Table 1). These suggest that the host substrate for phosphorite may not be the associated sediment. Similarly, based on petrography, we suggest that the host substrate in our phosphorite is not identical to those in pelletal phosphorites[17] and phosphatized microstromatolites[18].

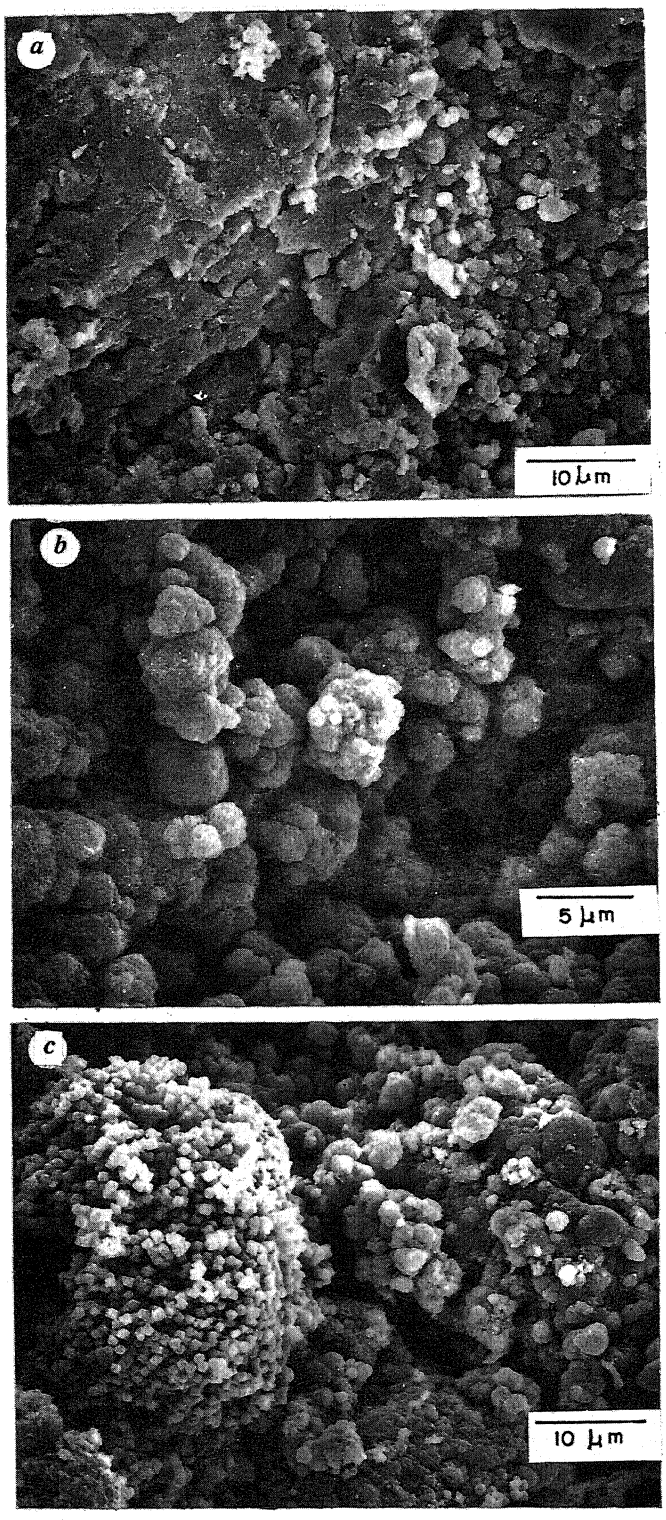

Figure 4. *a–c*, SEM photographs. *a*, apatite microstructure with moderately compact area with adjacent porous areas. *b*, porous area showing agglomerated apatite globules resembling phosphatized bacteria. *c*, Pyrite aggregate showing cubes and octoids of pyrite with adjacent area showing porous apatite microstructure corresponding to globules.

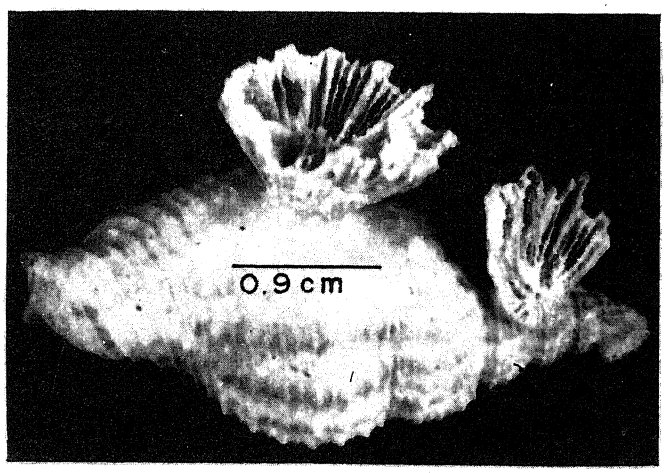

Figure 5. Photograph showing corals encrusted on a small gastropod shell.

The only possibility is that the initial substrate for the phosphorite crust may be a coprolite. Cayeux[19] described coprolites which show typical homogeneous and porous microstructure with few fish remains. More recently, Lamboy[20] reported copronodules from ODP cores of the Peru margin. Subsequent studies[9,10] have documented the homogeneous nannostructure of fish coprolites from various phosphorites including those from the ODP cores of the Oman margin. The observations in our phosphorite are in good agreement with the reports of these workers. It has been suggested that the faeces of carnivores contain highest P_2O_5 content (up to 11%) as they contain undigested remains of bone material and, those of herbivores seem to contain not more than 0.2–0.4% P_2O_5 (cf Slansky[21]). We therefore suggest that the initial excrement may belong to carnivore fishes and become phosphatized. The phosphorite thus produced subsequently became flat due to the overburden of sediment. Absence of hydroxyl apatite reflections in X-ray diffractogrammes, in spite of the existence of bone fragments and fish remains, may be due to the fact that the replacement of hydroxyl ion of the bone by fluoride ion is an ion exchange process and does not require major chemical alteration[21] and/or the total hydroxyl apatite in the sample is <5%.

The precise mechanism of apatite precipitation in coprolites is not known but may be similar to the one reported for authigenic minerals. (a) The major sources for phosphate were most probably the P released during early diagenetic degradation of organic matter and bone fragments associated with the initial excrement. (b) It is also known that dense populations of microbes inhabit the intestines of living vertebrates and their faeces normally contain abundant bacteria[22]. The presence of only agglomerated microspheres (Figure 4 *b*) resembling

phosphatized bacteria everywhere in the phosphorite may indicate the confined environmental conditions favouring the growth of only one type of microbial group. (c) The associated sediments do not contain pyrite whereas, the phosphorite crust contains several pyrite grains implying that the initial excrement itself may have acted as a restricted suboxic/anoxic microenvironment. In view of (a)–(c), we suggest that the microbes existing within the initial excrement assimilated P and F from within and also from the overlying waters, precipitated carbonate fluorapatite and phosphatized only coprolite in the confined microenvironmental conditions.

The initial excrements of fish are very fragile and may rapidly disintegrate with any small disturbance. The initial excrement was survived, phosphatized and indurated into a crust implying that very calm environmental conditions must have existed at the site during phosphatization. Growth of corals on a small gastropod shell (Figure 5) occurs close to the sediment interval of phosphorite crust. The transportation of these corals from elsewhere is ruled out as the sediment core under study was taken from a topographic high, an isolated feature on the continental slope (Figure 1). The encrustation of coral even on a small gastropod shell implies the prevalence of quiet conditions and low rates of terrigenous sedimentation. These conditions thus corroborate the phosphatization conditions of coprolite.

As the phosphorite crust is not occurring in upper 50 cm of the core, it is not a modern phosphorite. The age of the sediments in the core depends on the rates of sedimentation. The rate of sedimentation on the continental slope is about 4 mm/yr (ref. 23); these rates, however, cannot be used for our core as it was taken from a topographic high. Colour and texture of the sediments, organic carbon and calcium carbonate contents of the sediments significantly differ and vary in the sediments of the upper 40 cm of the core and the sediments below. This depth representing changing sedimentary conditions may correspond to Holocene/Pleistocene boundary. The sediment cores collected in the vicinity (Laccadive Sea) also showed similar sedimentary change at about 40 cm depth interval and based on the radiocarbon dates this depth interval has been suggested as Pleistocene/Holocene transition[24]. The rate of sedimentation during the Pleistocene was apparently low as evidenced by the phosphorite and coral encrusted gastropods at different levels. Even if we apply average sedimentation rate (2.2 cm/10^3 yr) recorded in the adjacent Arabian Basin[25], the sediments at 380–390 cm (phosphorite) interval might have deposited during the upper Pleistocene.

Palynofloral analysis of sections from Bharathi and Kundara clay mines of Kerala Basin: Palaeoecological and tectonic perspective

K. P. N. Kumaran, K. Soman*, C. V. Kamble and Ancy Joseph*

Geology & Palaeontology Group, Agharkar Research Institute, G. G. Agarkar Road, Pune 411 004, India
*Centre for Earth Science Studies, Trivandrum 695 031, India

The carbonaceous clay beds and lenses of peat belonging to Bharathi and Kundara clay mine sections of Warkalli Formation have yielded a well-preserved palynoflora. The assemblage represents a mixture of ecological groups such as low-land, freshwater, and sandy beach elements. The recognition of salt glands signifies that the palynoflora has affinity with mangrove swamp/coastal vegetation. The relative abundance of fungal remains is indicative of a high organic input environment and a warm, humid climate with heavy rainfall during the deposition. Occurrence of *Compositoipollenites, Malvacearumpollis, Quilonipollenites, Trilatiporites* and *Ctenolophonidites costatus* suggests Neogene (Miocene) age. The assemblage is contemporaneous of 'Ratnagiri Beds' of Maharashtra coast as they were deposited in a near-shore environment and their floristic composition is comparable. Nevertheless, the Warkalli deposits remained relatively stable unlike the 'Ratnagiri Beds' which have been subjected to post-depositional displacement caused by tectonic activity. Analysis of accrued fossil pollen evidence and disjunct distribution of plant taxa in a tectonic perspective have also been discussed.

DURING our studies on the kaolin deposits in the coastal tract of South Kerala, carbonaceous clay beds and small bands and lenses of peat have been observed in the ceramic clay mine sections of Bharathi and Kundara[1]. As these deposits contain rich organic matter, the samples have been subjected to palynological study in order to ascertain the floristic composition and also to derive palaeoecological information, which is the main objective of this communication. The samples investigated belong to the Upper Tertiary sedimentary sequence (Warkalli Formation) of the Kerala Basin[2].

The details of location (Figure 1) and clay mine profiles from where the samples were obtained are given below:

The Bharathi clay mine (8°37′38″:76°49′1″) is located at Sasthavattom of Thiruvananthapuram district. The mine section (Figure 2 *a*) shows 10–13 m thick bed of white clay, overlain by a soil column containing laterite pebbles, of thickness up to 6 m. A lens of peat (CC 28)

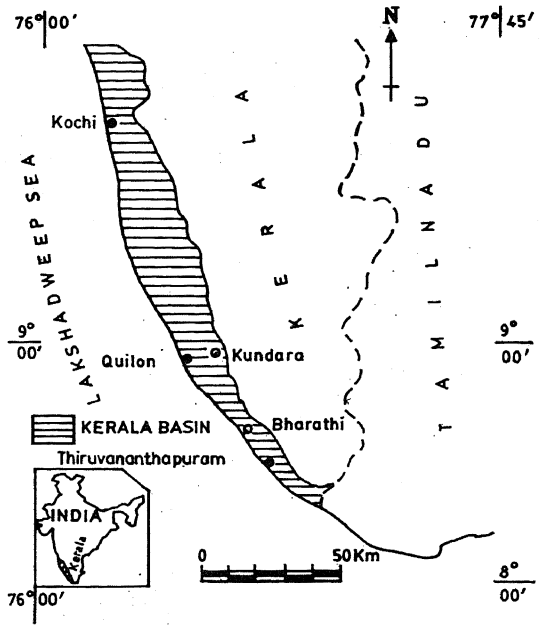

Figure 1. Map showing sampling localities.

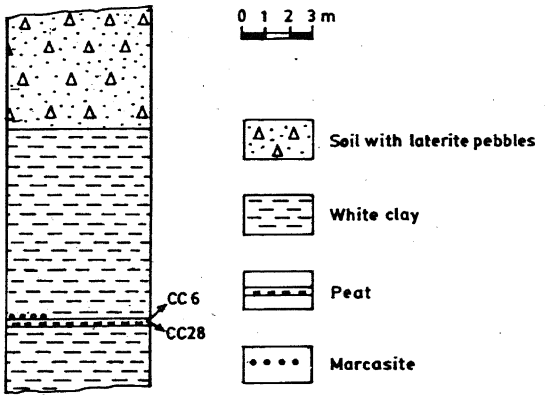

Figure 2 *a*. Synoptic profile of Bharathi clay mine, Sasthavattom.

with associated marcasite occurs at a depth of 13.5 m from the surface within the white clay bed.

The Kundara clay mine section (8°58′:76°40′6″) shows a massive thick sequence unconformably overlying the Precambrian crystalline gneiss (Figure 2 *b*). The maximum height of the southern wall of the mine is 50.7 m and the basal portion consists of residual clay having a thickness of 8 m. Residual clay is overlain by a sequence of sedimentary clay having thickness of 40 m and within this, carbonaceous clays, ball clays, variegated clays and pink clays occur alternatively. Although both the sections are separated by a considerable distance, the lithological features almost remain the same. Further field observations and details of synoptic profiles of Bharathi and Kundara clay mines have been dealt separately in the previous work[1,3].

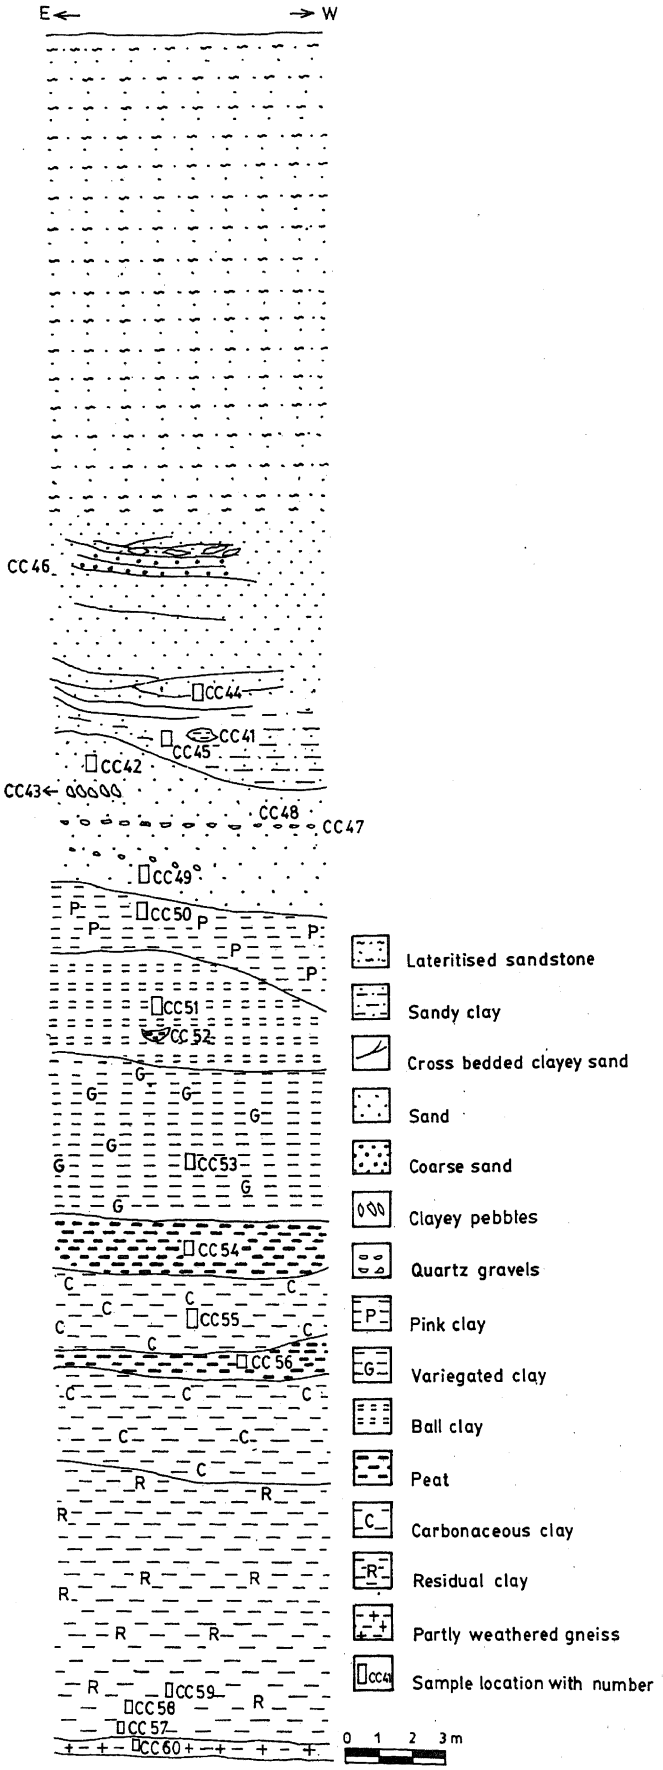

Figure 2 *b*. Synoptic profile of Kundara clay mine.

Table 1. Details of samples and location

Sample	Lithology	Location
CC-6	Carbonized wood	Bharathy Clay Mine, Sasthavattom
CC-28	Peat	Bharathy Clay Mine, Sasthavattom
CC-41	White clay	Kerala Ceramics Clay Mine, Kundara
CC-45	White clay	Kerala Ceramics Clay Mine, Kundara
CC-50	Pink clay	Kerala Ceramics Clay Mine, Kundara
CC-51	Ball clay	Kerala Ceramics Clay Mine, Kundara
CC-52	Peat	Kerala Ceramics Clay Mine, Kundara
CC-53	Variegated grey clay	Kerala Ceramics Clay Mine, Kundara
CC-54	Peat	Kerala Ceramics Clay Mine, Kundara
CC-55	Carbonaceous clay	Kerala Ceramics Clay Mine, Kundara
CC-56	Peat	Kerala Ceramics Clay Mine, Kundara

The samples analysed are mainly carbonaceous clays, peat and other clays. The details of samples analysed are given in Table 1. Of the 11 samples macerated, only six proved to be productive (CC28, 51, 53, 54, 55 & 56), while the rest, particularly white and pink clays, were found to be non-polleniferous. Palynomorphs recovered from the samples were processed using the conventional separation methods followed by the ultrasonic cleaning to get rid of the finer particles adhering to the palynofossils. The slides of figured specimens (Figures 3 *a–n*, 4 *a–t*) are deposited in the repository of palynological collections in the Geology and Palaeontology Laboratory for future reference.

The palynoflora recovered from the Bharathi and Kundara clay mines consists of pteridophytic spores, fungal remains and angiospermous pollen grains. Besides, the assemblage contains large number of cuticles, organic spherules and salt glands. The palynotaxa identified are given below:

Fungal remains: Spores and fruiting bodies

Dyadosporonites sp.; *Lirasporis* sp.; *Parmathyrites indicus* Jain & Gupta 1970; *Phragmothyrites eocaenica* Edward 1922.

Pteridophytic spores

Cheilanthoidspora monoleta Sah & Kar 1974; *Cingulatisporis* sp.; *Dandotiaspora plicata* (Sah & Kar) Sah, Kar & Singh 1971; *Osmundacidites cephalus* Saxena 1978; *Polypodiaceaesporites* sp.; *Polypodiisporites* sp.; *Lygodiumsporites* sp.

Angiospermous pollen grains

Compositoipollenites minimus Ramanujam 1987; *Crotonoidaepollenites euphorbioides* Rao & Ramanujam 1982; *Ctenolophonidites costatus* (V. H. Klinkenberg) V. H. Klink. 1966; *Dermatobrevicolporites dermatus* (Sah & Kar) Kar; *Droseridites spinosa* (Cookson) Potonie 1960; *Jandufouria seqmrogiformis* Germeraad,

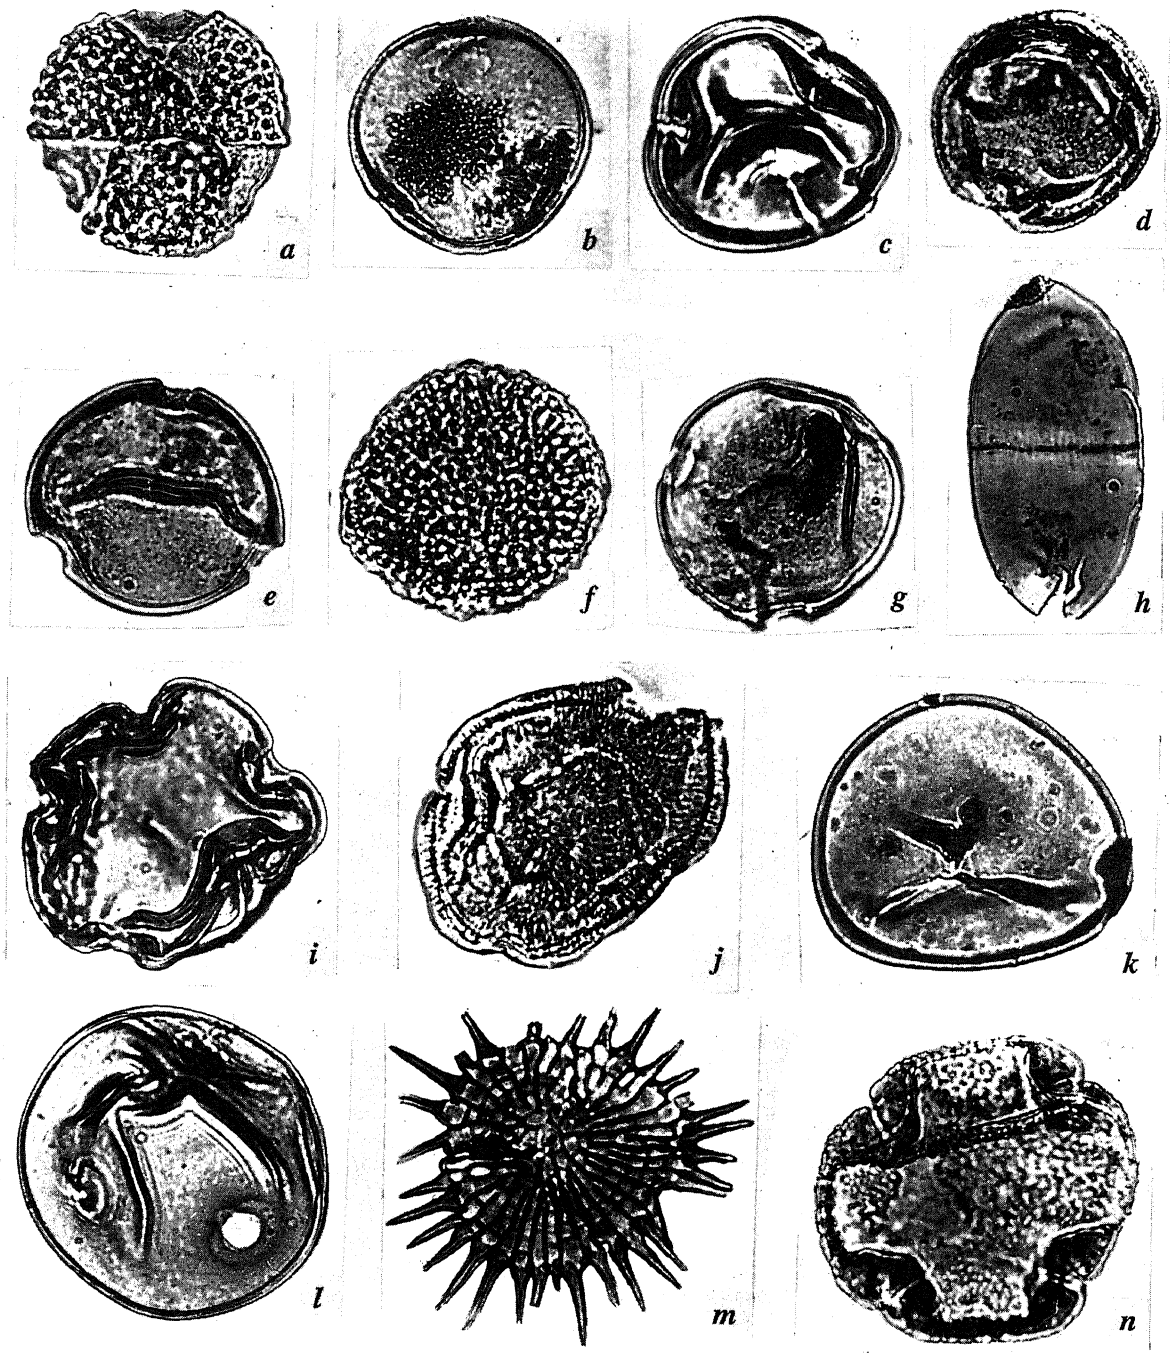

Figure 3. *a*, *Margocolporites tsukadai* Ramanujam. *b*, *Tricolporopollis* sp., *c*, Zonocolpate pollen grain. *d*, *Retitricolporites crassirotatus* Rao & Ramanujam; *e*, *Dermatobrevicolporites dermatus* (Sah & Kar) Kar; *f*, *Crotonoidaepollenites euphorbioides* Rao & Ramanujam; *g*, *Tricolporopollis* Rao & Ramanujam; *h*, *Dyadosporonites* sp.; *i*, *Meliapollis* sp.; *j*, *Jandufouria seamrogoformis* Germeraad, Hopping & Muller; *k*, *Dandotiaspora plicata* (Sah & Kar) Sah, Kar & Singh; *l*, *Lakiapollis ovatus*, Venkatachala & Kar; *m*, *Parmathyrites indicus* Jain & Gupta; *n*, *Meliapollis* sp. cf. *M. tamilii* Navale & Misra. (All photomicrographs are ca × 650).

Hopping & Muller 1968; *Lakiapollis ovatus* Venkatachala & Kar 1969; *Longapertites* sp.; *Malvacearumpollis estelae* (Germeraad, Hopping & Muller) Hekel 1972; *Margocolporites sitholeyi* Ramanujam 1966; *Margocolporites tsukadai* Ramanujam 1966; *Meliapollis tamilii* Navale & Misra 1979; *Meliapollis quadrangularis* (Ramanujam) Sah & Kar 1970; Rhizophoraceae (*Zonocostites*) type pollen grains; *Quilonipollenites* sp. cf. *Q. sahnii* Rao & Ramanujam 1978; *Retitricolporites crassirotatus* Rao & Ramanujam 1982; *Tricolporopollis* sp.; *Trilatiporites* sp.; *Tricolpites crassireticulatus* Dutta & Sah 1970; *Tricolporopilites pseudoreticulatus* Kar 1985; Zonocolpate type.

Of the above-mentioned species, *Margocolporites* are abundant in the assemblage. *Meliapollis* is also fairly represented. Pollen grains belonging to Rhizophoraceae

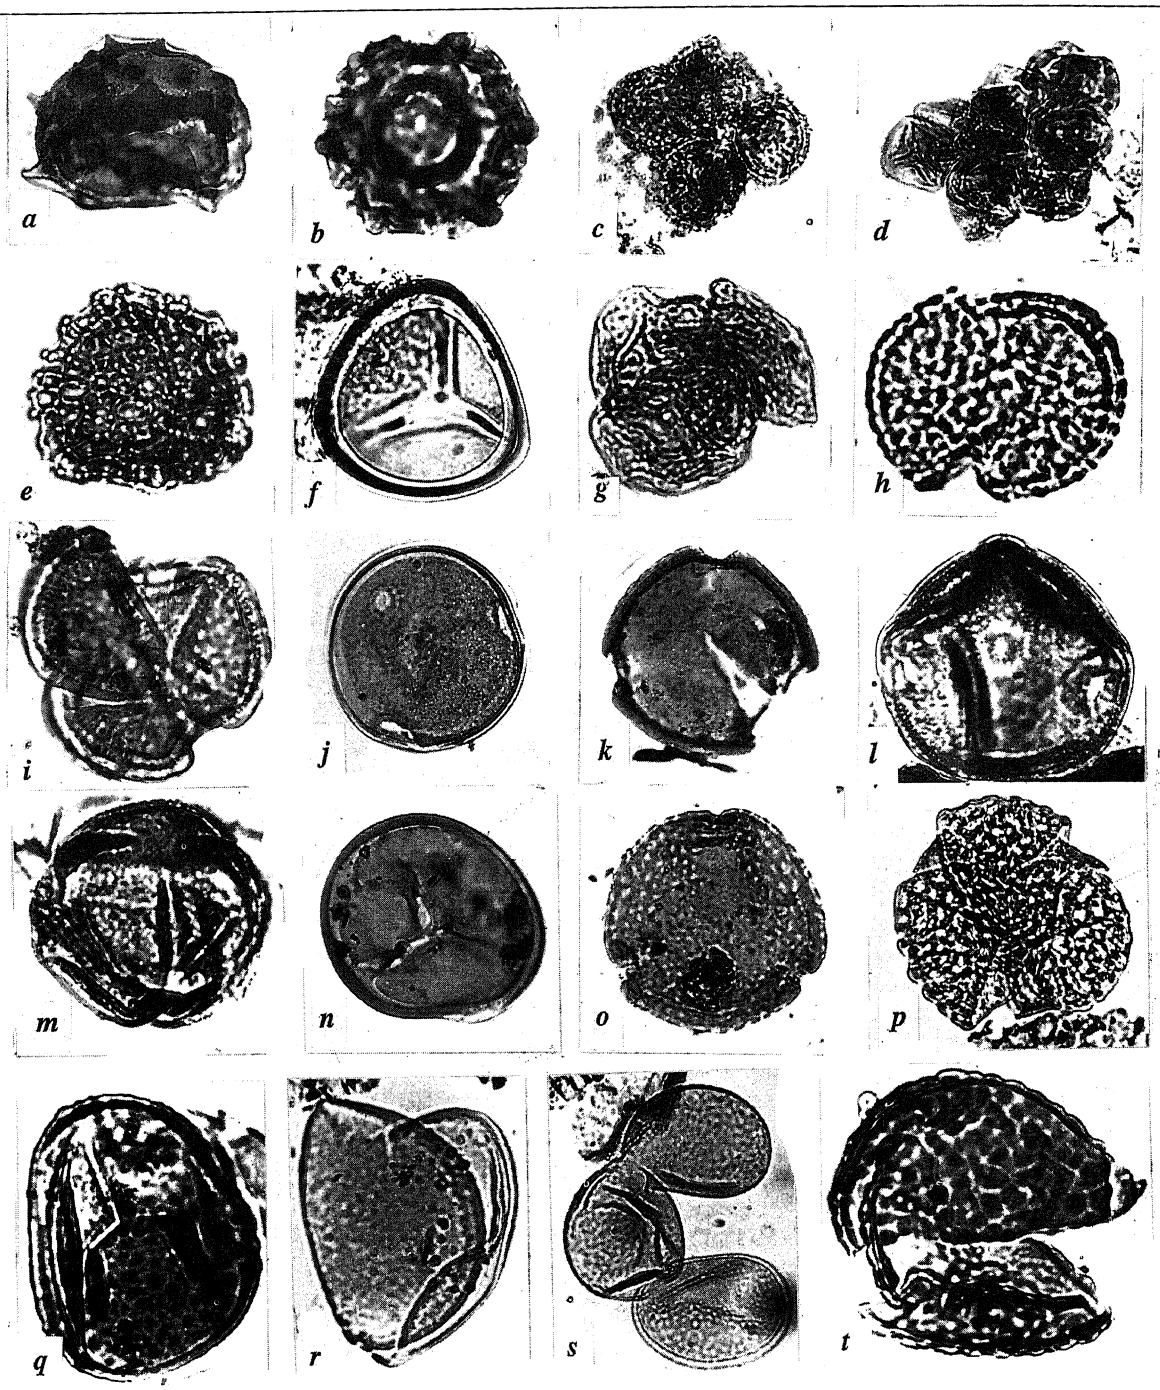

Figure 4. ***a***, *Malvacearumpollis estelae* (Germeraad, Hopping & Muller) Hekel; ***b***, *Ctenolophonidites costatus* sp. (Van Hoeken-Klinkenberg) Van Hoeken-Klinkenberg; ***c***, *Droseridites spinosa* (Cookson) Potonie; ***d***, *Palaeosantalaceaepites* sp. (Group of pollen grains); ***e***, *Cheilanthoidspora monoleta* Sah & Kar; ***f***, *Cingulatisporites* sp.; ***g***, ? Group of Monocolpite finely reticulate pollen grains; ***h***, *Quilonipollenites* sp.; ***i***, *Tricolpites crassireticulatus* Dutta & Sah; ***j***, *Tricolporopollis* sp.; ***k***, *Meliapollis quadrangularis* (Ramanujam) Sah & Kar; ***l***, *Trilatiporites* sp. cf. *T. normei* Ramanujam; ***m***, *Retitricolporites crassirotatus* Rao & Ramanujam; ***n***, *Lygodiumsporites* sp.; ***o***, *Tricolporopilites pseudoreticulatus* Kar; ***p***, *Margocolporites sitholei* Ramanujam; ***q***, *Osmundacidites cephalus* Saxena; ***r***, *Longapertites* sp.; ***s***, *Polypodiaceaesporites* sp. (3 spores together); ***t***, *Polypodiisporites* sp. (All photomicrographs are ca × 550).

(*Zonocostites*) occur mainly in groups attached to cuticles. *Lakiapollis ovatus* is another significant taxon of the assemblage. *Polypodiisporites* and *Polypodiaceaesporites* of Polypodiceae are the important elements of the Pteridophytes. Only some of the forms have been assigned to earlier published taxa, whereas others are referred to informal species.

The occurrence of *Ctenolophonidites, Droseridites, Jandufouria, Lakiapollis, Malvacearumpollis, Margocoloporites, Meliapollis* and *Zonocostites* type of pollen

grain in the assemblage is significant as they are of stratigraphical and palaeocological importance[4–8]. The assemblage as a whole represents a mixture of ecological groups such as low-land, freshwater, mangrove and sandy beach elements, particularly that of the Bharathi clay mine. However, in the Kundara clay mine, the palynofloral spectrum could be differentiated at various levels of sampling. For example, sample CC-56 yielded mainly pteridophytic spores while CC-55 is rich in *Tricolpites crassirotatus*. The occurrence of angiospermous pollen grains namely *Margocolporites tsukadai* and *Meliapollis* spp. has been found to be increasing towards higher levels of sampling in the section. Fungal fruiting bodies are abundant, indicating heavy rainfall and high humidity. The recognition of salt glands in the sediments signifies that the palynoflora has an affinity with mangrove swamp/coastal vegetation. Presence of *Compositoipollenites, Malvacearumpollis, Margocolporites, Meliapollis* spp., *Quilonipollenites* and *Tricolporopilites* indicates that the carbonaceous clays and peat samples belong to the Upper Tertiary[4–11].

The palynofloral assemblage does compare well with the other known contemporaneous deposits of the West coast as they have common floral elements. The palynoflora obtained from the 'Ratnagiri beds' resting on Deccan Trap having a few metre thickness, at Kotwade, Bankhot-Velas and Parchuri of Ratnagiri district of Maharashtra State have several comparable taxa. As this flora[12] was recovered from the deposits which occur at higher altitude of 100–120 m ASL, the assemblage described here comes from a considerably lower altitude, indicating that the former has been subjected to uplift during the post-Miocene age as suggested by several workers[13,14] while the deposits studied here were accumulated in a basin which remained relatively stable as reported earlier[15–17].

Although palynological work has been done covering the Warkalli, the Quilon and the Vaikom formations, a finer resolution of the age of the entire sedimentary sequence of the Kerala basin is yet to be achieved[7]. Most of the published reports on palynoflora are sporadic covering either of one or two formations. Moreover, palynological data of the subsurface sediments are meagre to have meaningful biostratigraphy and to correlate the entire Tertiary sequence overlying the Archean basement. Therefore, it would be worthwhile to analyse more subsurface samples collected from widely drilled boreholes from Kanyakumari in the South to Kasargod in the North for finer resolution of age and a better understanding of palaeoecology and vegetational history of the Kerala coast using palynology as a tool.

Considering the pronounced neotectonic activity along the Maharashtra coast compared to the Kerala deposits, there would be further scope in analysing the palynological evidence for reasonable estimates of dispersal probabilities of several taxa that had been growing along the West coast of India. The palynological evidence *vis-à-vis* present day distribution[18] of *Ctenolophon, Durio, Pentac, Sclerosperma, Syagrus, Nyssa, Elaeis, Gunnera, Kielmeyera, Nypa* and *Eugeissona*, to mention a few, does indicate that ecological stress brought about by tectonic activity might have played a decisive role in their displacement from the West coast of India. However, we have yet to establish the probable reasons for their disjunct distribution and restricted occurrences at oceanic distances as we do not have a comprehensive analysis of pollen data from the West coast. As not much thought is given to the phenological response/readjustment of the species[19] in relation to plate tectonic activity, it would be worth examining the palynological data that are being accrued in that perspective. We have to ponder and adopt a holistic approach[20] so that the role of tectonic activity and the accompanying change in physiography and climatic vicissitudes in geosphere and phytosphere could be understood in a much better way.

Bioremediation of toxic metal ions from polluted lake waters and industrial effluents by fungal biosorbent

Md. Naseem Akthar and P. Maruthi Mohan

Department of Biochemistry, Osmania University, Hyderabad 500 007, India

Alkali-extracted mycelial biomass (biosorbent) from *Aspergillus niger* was effective in sequestering metal ions, especially Zn^{2+} and Cd^{2+} from lake waters from very low concentrations (μg/l) when compared to Dowex-50. Zinc ions (9 g/l) from an effluent of a battery manufacturing unit could be removed efficiently (>75%) by recycling the biosorbent through five cycles. Similarly, chromium ions from effluents of electroplating industry (420 mg/l) could also be removed by recycling the biomass. Here we report the potential use of this fungal biosorbent in removing toxic metal ions from heterogeneously polluted lake waters and industrial effluents.

DEVELOPING countries are increasingly concerned with pollution due to toxic heavy metals in the environment. Unlike most organic pollutants which can be destroyed, toxic metal ions released into the environment often persist indefinitely, circulating and eventually accumulating throughout the food chain, thus posing a serious threat to mankind. Large proportions of heavy metals are being released into the environment from acid mine drains and industrial waste waters due to inadequacies of technology in processing of metals or through other routes[1,2]. A reasonable procedure to diminish the escape of metals from industrial effluents is the adoption of low waste-generating technologies coupled with effective effluent treatment.

The use of biological materials for heavy metal removal or recovery has gained importance in recent years due to their good performance and low cost[3–7]. Among the various sources, both live and inactivated biomass of microorganisms exhibit interesting metal-binding capacities[8,9]. Their complex cell walls contain high content of functional groups like amino, amide, hydroxyl, carboxyl, sulphydryl and phosphate which have been implicated in metal binding[10–14].

Conventional methods for removing metals from industrial effluents before they are disposed off are becoming inadequate, while effective methods are becoming uneconomical[15]. An alternative method, based on the adsorptive capacity of microbial biomass, referred to as biosorption, is emerging as a promising 'biosorption technology' for metal removal and recovery[3,4,16]. Studies from our laboratory had earlier used a nickel-resistant, hyperaccumulating mutant of *Neurospora crassa* to remove toxic Ni^{2+} from aqueous media[17]. In later studies, alkali-extracted mycelial biomass of *N. crassa, Fusarium oxysporum* and particularly *A. niger* have been demonstrated to have an excellent ability to concentrate silver ions[10]. Further, the mechanism of biosorption was demonstrated to be by a direct exchange of toxic ions with resident Ca^{2+}/Mg^{2+} of the biosorbent; carboxyl groups have been shown to be the major binding groups herein[11]. The objective of the present study is to explore the potential use of a biosorbent from *A. niger* in removing toxic metal ions from polluted lake waters and industrial effluents.

The biomass of *A. niger* was processed as described earlier[10], referred to as 'biosorbent' was used in all experiments. For metal-removal experiments, Hussain Sagar, an eutropically polluted lake in the Hyderabad city, India, was chosen and the metal ion concentrations (Cd^{2+}, Cu^{2+}, Co^{2+}, Ni^{2+} and Zn^{2+}) were determined[18]. The biosorbent (25 g fresh weight = 5 g dry weight) was taken in a cheese cloth bag and dipped into the lake waters (2–3 feet deep) for 60 min. The biosorbent was then removed, washed with distilled water and the bound metals were eluted with 0.1 N HCl. The eluate was concentrated and the amount of metals bound was anayysed by Atomic Absorption Spectrophotometry (AAS, Perkin–Elmer Model No. 2380). Simultaneously for comparison of efficiency of the biosorbent, 5 g of Dowex-50 (Na^+ form) was taken in a cheese cloth bag and dipped into the lake waters and the experiment was carried out as described above for biosorbent.

For the removal of metals from industrial effluents, biosorbent (2 g) was suspended in 20 ml of the effluent and incubated on a rotary shaker (100 rpm) at 30 ± 1°C for 1 h and the amount of metal remaining was analysed. The biosorbent was reused for 5 cycles after regenerating with Ca^{2+} and Mg^{2+} (0.1 M each) as described earlier[10].

Microorganisms have applications in selected wastewater metal removal/treatment systems. However, toxicity of metallic contaminants and the highly variable conditions prevalent in many wastes and processed waters preclude the use of living organisms and necessitate the utilization of non-living systems for metal removal. Metal sorption has been well demonstrated with nonmetabolizing and nonliving, microbial biomass[16,19,20]. Several characteristics of inactive biomass make it an ideal choice for treatment of metal containing waste waters and process streams[21,22]. Inactive biomass, in general, is not selective in the metal sorbed; rather, it simultaneously removes several different toxic and heavy metals like Cd, Cr, Cu, Hg, Ni, Pb, U, Zn from solution regardless of their concentrations. In addition, the biomass has greater avidity to and removes metals that are relatively more hazardous, due to its low affinity for alkaline earth metals (Ca, Na, K, Mg) (ref. 23).

Most studies described above have been conducted using metal ions in pure solutions and very few have

Table 1. Sequestration of toxic metal ions from lake waters.

Metal ion	M^{2+} in lake water µg/l*	Amount of metal bound µg/5 g		Litre** equivalents
		Biosorbent	Dowex-50	
Cd^{2+}	8.63 ± 6.5	333.8 ± 155.5	8.69 ± 4.97	38.7
Cu^{2+}	18.1 ± 14.5	85.1 ± 41.2	21.94 ± 9.3	4.7
Zn^{2+}	62.3 ± 21	4562.5 ± 1174.3	111.9 ± 67.3	73.2
Ni^{2+}	17.98 ± 7	90.13 ± 52.48	6.35 ± 3.37	5.3
Co^{2+}	10.65 ± 1.1	84.69 ± 36.75	7.75 ± 2.95	7.9

*Five samples were collected from the same site of the lake over a period of one year and pH varied between 7.9 and 8.5.
**Obtained by dividing biosorbent-bound metal ion by the lake water metal concentration per litre.
Biosorbent or Dowex-50 (5 g) placed in a cheese cloth bag and immersed into lake water (2–3 feet deep) for 60 min. The bound metal ions were desorbed and estimated by AAS (see text).

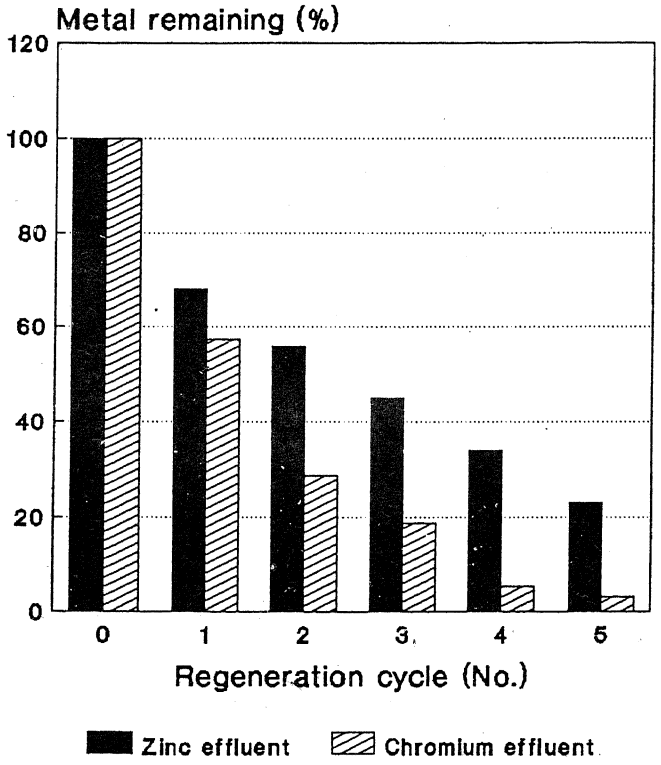

Figure 1. Biosorbent (2 g) was suspended in 20 ml of effluent containing zinc (9 g/l) or chromium (420 mg/l) for 60 min. The metal ion remaining was estimated by AAS. After regeneration, the bisorbent was reused up to 5 cycles (see text).

used industrial effluents to our knowledge[24,25]. In the present study, we have used the polluted effluents directly without manipulating their composition. The results show that cadmium and zinc were more effectively sequestered from the lake waters at very low concentrations (ppb or µg/l) as compared with other metal ions by the biosorbent. The efficacy of the biosorbent *vis-à-vis* equal weight of Dowex-50 indicated the former's superiority in binding metal ions (Table 1). This is due to Dowex-50 readily binding nonspecifically divalent ions present in lake waters (like Ca^{2+} and Mg^{2+}), thereby attaining saturation with these ions (data not shown) and being there after unable to sequester toxic ions present at very low concentrations. If the binding capacity of the biosorbent is calculated on the basis of litre equivalents, the biosorbent (5 g) is able to remove almost 75 l equivalents of zinc and around 40 l equivalents of cadmium: for copper, cobalt and nickel, equivalence was around 5–10 l (Table 1). The metal ion concentrations noted here are well below the permissible limits suggested by the Indian Council of Medical Research[26]. It should be noted here that when the same metal ions were present in a mixture at high concentrations (25 mM each), the order of binding by the biosorbent (from pure solutions) was Cu > Zn > Cd > Co = Ni (ref. 11). This shows that other unknown factors influence the order of preference for metal sorption from such heterogeneously polluted waters.

Zinc removal from an industrial effluent (from a battery manufacturing unit) which contains a high concentration of zinc (9 mg/ml) was highly effective with the biosorbent; five cycles of biosorbent treatment resulted in more than 75% metal removal. In another effluent from an electro plating industry containing chromium (420 µg/ml), the biosorbent was able to remove more than 95% of chromium (five cycles). One of the interesting features regarding Zn^{2+} sequestration from effluent of a battery manufacturing unit is that in the first cycle of use (Figure 1) about 30% of Zn^{2+} is removed by the biosorbent (60 mg zinc/2 g fresh wt). On a dry weight basis, this amounts to 15% of biosorbent weight (as dry weight accounts for 20% of fresh weight). In earlier studies[11], Zn^{2+} binding was 9–10% from a pure solution containing 50 mM (about 3 mg/ml). The higher binding noted herein is possibly due to a 3-fold higher concentration of Zn^{2+} present in the effluent. The accumulation of toxic metal ions is based on a mole for mole exchange with the resident calcium and magnesium ions of the biosorbent. The low affinity of Ca^{2+} and Mg^{2+} ions for the biosorbent makes them excellent counter ions for the heavy metals that form more stable complexes with the unprotonated binding sites. This factor has been taken as an advantage for the regeneration of the biosorbent and its repeated use[11].

Ideal properties for a biosorbent are: i) it should sequester toxic metal ions both from dilute and concentrated solutions, ii) should not face antagonism with essential metal ions, iii) should be reusable, iv) should not by themselves contaminate the environment. Overall, the biosorbent used in the present study has most of these features. Further scale-up studies are required to determine the actual potential of this biosorbent for decontaminating metal ions from industrial effluents.

Received 4 July 1995; revised accepted 7 November 1995

Deep Continental Structure of India: A review. T. M. Mahadevan, Geological Society of India, P.B. No. 1922, Bangalore 560 019. Memoir 28. 1994. 569 pp. Price: Rs 600/$60.

The book under review is a monumental compilation of geophysical field research on deep continental structure of India. A short preface summarizes the scope and objectives and expresses the hope that this work will help to bridge a communication gap between geologists and geophysicists, for whom deep continental studies are common ground. The text begins with (1) 'General Considerations', which briefly defines the Indian continental crust and its geographical extent along with geological and geophysical characteristics, particularly of its lower crust, Moho and upper mantle. In Chapter 2, 'Technology and Methods – Present Status', a short description of the geophysical techniques for imaging the deep interior is highlighted, with emphasis on standards in technology. The contents of this chapter would make the reader feel that a comparative attempt has not been made of the synthesized data from different methods for the Indian lithosphere or any of its seven tectono-stratigraphic units specified in the next chapter. Chapter 3, 'The Indian Crust', deals with the results of various geophysical investigations of the seven major geological entities. Here the author has summarized the informations of velocity structures, heat flow, Himalayan isostasy, etc., without their critical evaluation. Chapter 4, 'Peninsular Shield – Precambrian Cratons and Mobile Regions', gives some broad features of geology and deep crust. A vital problem is emphasized as to whether the Indian plate has evolved by collision and fusion of a number of microplates or it was a single ancient continental crust that underwent intermittent rifting to form sedimentary basins which finally developed into foldbelts now seen bordering the cratons. In Chapter 5, 'Purana Basins', the author considers these basins as Proterozoic analogues of the Tertiary basins that occur in front of the Himalayan orogen, although the available geophysical information does not support, except for the Cuddapah basin. In 'Gondwana Basins', described in Chapter 6, the horst and graben structures are revealed in gravity and DSS profiles. Despite the shallow basin bottoms, some basins like Godawari and Mahanadi are interpreted as zones of intra-continental passive rifts without establishing their Precambrian ancestry. Chapter 7, 'Mesozoic-Tertiary Volcanic Province', gives an account of all possible evolutionary models but the geophysical inputs have not been always used as evidence in support or against any of these models. The author has followed a simple theory where positive gravity field is attributed to rising Moho or to the presence of basic/alkaline rocks, while negative field is taken to indicate sediments. The Sonata belt is elaborately described but this reviewer feels that no definite conclusions can be drawn from the geophysical data alone for the evolution of this major tectonic divide of Sonata. In Chapter 8, 'Younger Sedimentary Basins', a significant feature is their horst and graben structures. The Cambay basin is classed as a failed arm with Kutch basin and Sonata belt as other two arms of a triple junction, akin to the Afar triangle from which three rift systems radiate. But this hypothesis would be misleading to earth scientists as the geological and geophysical methods have not yet been evaluated in this direction. The section on geomagnetic field and conductive structures on page 327 appears somewhat out of place in this chapter. In Chapter 9, 'Himalaya', the gravity and seismic data have been synthesized with surface geology, but different evolutionary models are simply stated. The reader is, however, left to himself to relate the geophysical data with the vertical tectonics or plate tectonics that have been responsible for the Himalayan orogeny. While not competent on Chapter 10, 'Continental Margins of India', I am confident that this will be welcomed as a reliable compilation. In Chapter 11, 'Emerging Scenarios of Deep Continental Structures – A Resume', an attempt is made to synthesize the various geophysical data on deep continental crust of India. Considering thickness as most useful parameter, the Moho depths and lithospheric thickness are summarized in tables. The review is a worthy attempt and quite elegantly examines models already presented without their critical evaluation. The last Chapter 12. 'Framework for Future Programme', contains useful recommendations, although with a long list. A multidisciplinary, integrated and careful planning is recommended for future researches on deep continental structures of India. There is truly magnificient list of about 900 references.

The vast geophysical information contained in this volume will prove useful in establishing deep crustal interaction with surface geology. The text is clear and on the whole very readable, except when some of the arguments and statements appear to be out of context and when long sentences make severe demands upon the reader's power of concentration. The book is not without minor flaws. Some figures are nearly illegible or fuzzy because of extreme reduction, a few illustrations are incorrectly labelled and the text has a few typographical errors. However, the volume contains so much valuable material assembled in so useful a form that one can hope it will be widely disseminated and read. One must salute the courage and patience of the author who, being a geologist with vast experience, ventured for the first time in reviewing the massive geophysical work on a request from the Department of Science and Technology, New Delhi, which initiated modern research activities on Indian deep continental crust.

Rice Tungro A. Anjaneyulu, M. K. Satapathy and V. D. Shukla. Oxford and IBH Publishing Co. Pvt. Ltd., New Delhi, Bombay, Calcutta, 1994, 228 pp.

Rice is a staple food for human beings. Rice tungro virus is considered as one of the major constraints in rice production in South East Asia. For many years plant virologists, plant pathologists and entomologists have done research on tungro virus disease. Prior to this publication comprehensive review was not available. This book fulfils the needs of the researchers and the students who wish to gain a fair degree of knowledge on tungro virus disease.

The text has been divided into 19 chapters. Chapter one presents an overview of tungro virus disease. The occurrence, distribution and area affected in different parts of the world have been clearly indicated in the map (chapter 2). Symptoms are important in any disease

diagnosis. Range of symptoms by different strains of virus on different rice cultivars has been described. Symptoms induced by feeding vector leafhoppers are also given (chapter 3). The management strategy depends upon yield loss. Though yield reduction on different varieties has been given yield loss per unit area is not provided (chapter 4).

For many years the cause of the disease was not known. Rice tungro is caused by bacilliform particles of 25 x 140 nm and spherical particles of 28–30 nm in diameter. Antisera has been raised against both the particles of tungro virus. This is most useful in the detection and epidemiology. Various diagnostic techniques have been described in chapters 5 and 6.

Molecular biology of tungro virus is most interesting because of two viruses; RNA virus and DNA virus associated in causing the disease. Only limited information is available on this (chapter 7). Existence of several strains of RTV (RTV 1, RTV 2, RTV 2A, RTV 2B, RTV 3, RTV 4) in different rice-growing areas has been described (chapter 8). Little attention has been paid to the metabolic processes associated with the symptom development of rice plants infected with tungro viruses despite its widespread occurrence and economic importance (chapter 9).

Tungro viruses are transmitted by various species of *Nephotettix*. The authors have described vector distribution, virus–vector relationships, biology, host range and vector movement (chapters 10–12). The epidemiology of tungro disease is interesting because of the involvement of insect vector, besides host (rice), pathogen (RTSV & RTBV) and environment. Presence of virus strains, vector biotypes, multiple rice cultivars, alternate weed hosts and different cultural practices make tungro epidemiology very interactive and disease development becomes a function of various aspects of virus, host, agronomic practices and materiological factors (chapter 13). Tungro viruses, their transmission, virus–vector relationship, vector biology, population dynamics of the vector and host resistance have been discussed (chapters 10–13). Various ways and means have been attempted and different recommendations have been made in different Asian countries to reduce the disease incidence and increase the crop yields (chapter 14). Varietal resistance has been discussed in a separate chapter (chapter 15). An interesting aspect is a note for farmers and extension workers provided in the book (chapter 17), besides future prospects (chapter 18). All the literature published on rice tungro is provided in the book (chapter 19) and subject index is given for easy reference.

The book is an outstanding contribution with application of data, diagrams and illustrations. I hope it will be useful to plant pathologists, plant virologists, entomologists, extension workers and students and teachers of general agriculture.

Bacterial Pathogenesis of Plants and Animals: Molecular and Cellular Mechanisms. J. L. Dangl, ed. Current Topics in Microbiology and Immunology series, Springer-Verlag, Berlin, Heidelberg. 1994. Vol. 192. 343 pp.

Although four highly authoritative books (*Molecular Basis of Bacterial Pathogenesis* eds Barbara H. Iglewski and Virginia L. Clark); *Molecular Biology of Bacterial Infection: Current Status and Future Perspectives* (eds Hormaeche, C. E., Penn, C. W. and Smyth, C. J.); *Bacterial Pathogenesis: A Molecular Approach* (eds Abigail A. Salyers and Dixie D. Whitt); *Molecular Genetics of Bacterial Pathogenesis* (eds Miller, V. L., Kaper, J. B., Portnoy, D. A. and Isberg, R. R.). For reviews see *Curr. Sci.*, 1993, **64**, 118–119; 1993, **65**, 798–799; 1995, **68**, 343–344; 1995, **69**, 624–625) have already appeared on the molecular underpinnings of bacterial pathogenesis, the slant of this volume is entirely different. This is apparent, at the outset, from the somewhat non-obvious choice of topics which include both plant and animal pathogens. The objective of this volume is to bring out the commonalty of molecular mechanisms which underlie bacterial pathogenicity, irrespective of the type of the pathogens – plant or animal, and thus underscore the importance of basic research approaches to parallel problems in pathogenesis.

The first basic concept about bacterial pathogenesis, whether plant or animal, which one realizes while going through this volume is the multiplicity of virulence factors required. Beattie and Lindow discuss various virulence factors which determine the epiphytic fitness of phytopathogenic bacteria. This is analogous to attachment and colonization of host surfaces by the animal pathogens as detailed by Meyer *et al.* and Manning in their reviews on the pathogenicity of *Neisseria* spp. and *Vibrio cholerae* respectively. From these reviews, it is evident that while not much is known as to the molecular mechanisms underlying various virulence factors, viz. fimbrial adhesions, extracellular polysaccharides (EPS), osmotolerance, tolerance to UV and visible radiations, etc. determining the epiphytic fitness of phytopathogenic bacteria, detailed information is available on the molecular genetics of colonization factors of animal pathogens such as Tcp (*t*oxin *c*oregulated *p*ilus) and Acf (*a*ccessory *c*olonization *f*actor) of *Vibrio cholerae*, and pili and opa (*op*acity *a*ssociated) proteins of *Neisseria* spp.

The next basic concept which one realizes is the complexity of genetic regulatory pathways controlling expression of virulence determinants in bacterial pathogens. Dow and Daniels discuss global regulation of virulence determinants, viz. extracellular enzymes (cellulase, protease, polygalacuronase lyase, amylase and lipase), EPS, xanthan, etc. of *Xanthomonas campestris* pv. *campestris*. This is a clear reflection, among animal pathogens, of *bvg* locus of *Bordetella pertussis* as detailed by Rappouli. The review by Dow and Daniels also shows that environmental modulation of virulence determinants in phytopathogenic bacteria, as is well known for the animal pathogens, is also regulated by two-component signal transduction mechanisms. The existence of two-component regulatory systems in phytopathogenic bacteria is further corroborated by studies on the genetic and chemical bases of recognition in *Agrobacterium tumefaciens* as reviewed by Binus and Howitz.

The extracellular products produced by both animal and plant bacterial pathogens represent a group of 'most obvious' virulence determinants. Collmer and Bauer, choosing two quite different plant pathogens namely *Erwinia chrysanthemi* and *Pseudomonas syringae*, discuss the molecular genetics of extracellular virulence proteins. In doing so the authors put maceration, pectic enzymes and *pel* genes *vis-a-vis* hyper-

sensitive response (HR), hairpins and *hrp* genes. The concluding section of this review is very interesting in which the authors compare pathogenicity of *Erwinia chrysanthemi* with that of *Pseudomonas aeruginosa* and *P. syringae* with *Yersinia pestis* (reviewed in this volume by Cornelis), thus bringing out similarities/dissimilarities in the deployment and functions of their extracellular virulence proteins. The review by Cornelis is a detailed account of the molecular genetics of yops, the extracellular virulence proteins produced by *Yersinia pestis*.

An extensive review by Bonas discusses structural organization and functions of *hrp* (*h*ypersensitive *r*eaction and *p*athogenicity) genes and *hrp*-dependent secretion of hypersensitive response-inducing proteins (hairpins) in *Erwinia amylovora* and *Pseudomonas syringae* pv. *syringae*. Among the animal pathogens this system can be compared, in the larger perspective, to a number of virulence genes of *salmonella* (reviewed by Finlay). The various genes of *Salmonella* which are under intensive investigation are: *Spv* (*S*almonella *p*lasmid *v*irulence) *Spa* (*S*almonella *p*resentation of *a*ntigen) and *pag* (*Pho-P a*ctivating *g*enes).

The commonalty of the molecular and cellular mechanisms among bacterial pathogens producing quite different clinical disease entities is illustrated by the study of *Shigella flexneri* and *Listeria monocytogenes* as reviewed by Parrot and Sheehan *et al.* respectively. Although quite different as to the clinical disease produced, these pathogens show several similarities in their cytoplasmic multiplication, actin-based movements and cell-to-cell spread.

In a detailed review entitled 'enigmatic avirulence genes of phytopathogenic bacteria' Dangl discusses whatever little is known about the organization, regulation and virulence functions of avirulence (*avr*) genes, bringing into focus some of the paradoxical issues of the topic and posing several questions which must be explored further to understand their exact role in pathogenesis.

A very important question which emerges from the foregoing discussion is: taking cues from animal pathogens, where molecular genetics of pathogenicity are decidedly better understood, can we address ourselves to some of the hitherto unsolved issues of plant pathogens or even vice-versa? This question has been posed more convincingly by McKhann and Hirch in their review on *Rhizobium*. Arguing from several points of view the authors show that there are important conceptual differences between symbiotic and plant pathogen interactions and suggest that *Rhizobium*-legume symbiosis cannot be regarded as a modified or refined type of plant pathogen interaction as proposed by some investigators sometimes back. They further suggest that to understand root hair invasion by rhizobia we should, perhaps, look into models representing invasion of mammalian cells by bacterial pathogens.

The objective of this intellectually stimulating volume is to make the readers view bacterial pathogenicity from newer perspectives. Seen in this context, the volume in its totality is a laudable attempt and a novel addition to works already available on the subject. However some of the reviews, when seen individually, tend to look aloof and wanting in overall objectives of the compilation. This apart each review, whether dealing with plant or animal pathogens, gives detailed information on the molecular and cellular mechanisms underlying the bacterial pathogen discussed. Each review has been provided with an extensive and up-to-date bibliography.

This volume is strongly recommended as part of any collection of books dealing with microbiology. The volume will be of much use to researchers studying various aspects of the molecular genetics of bacterial pathogens and to teachers engaged in teaching advanced level courses on bacteriology plant or animal bacterial pathogenesis and infectious diseases.

INSTITUTE FOR PLASMA RESEARCH

(An Autonomous Institute of DST, Government of India)
Near Indira Bridge, Gandhinagar Highway,
BHAT, GANDHINAGAR 382 424

ADVT NO. 09/95

FACULTY AND POST DOCTORAL POSITIONS IN SURFACE AND MATERIAL SCIENCES

The Institute for Plasma Research is the country's premier research institute pursuing research and development in plasma physics and its applications. The institute has been established by the Department of Science and Technology, Government of India to lead the country's Plasma Physics and Magnetic Confinement Fusion Research Programme.

Tokamak 'Aditya' is in operation and a steady state superconducting tokamak (SST) is under design. Other areas of thrust are basic plasma physics, fusion technologies, plasma-assisted material processing, computer simulation, etc. Improved understanding of plasma–surface interaction is important from the point of view of design and engineering of magnetic confinement fusion devices and plasma-assisted material processing. In the former the degradation of integrity of plasma facing components and the control of evolution of impurities are the issues of critical importance, while in the latter, technologies like surface engineering are based on our understanding of plasma–surface interaction.

IPR is planning to strengthen its activities in this field. A full-fledged surface and materials characterization laboratory with advanced instrumentation like ESCA, XPS, AES, SIMS, SEM, XRD, etc. is being established.

We are looking for scientists at the faculty level like Associate Professor – I & II, Fellow, Scientist – SD and Post-Doctoral Fellow to initiate and lead the programme at IPR. While the thrust will be on goal-oriented research and development mentioned above, individual scientists will have considerable freedom to pursue their own special interests.

FACULTY AND POST DOCTORAL POSITIONS

Qualification and Experience: Ph D with adequate research experience in material and surface analysis and characterization using the above-mentioned techniques.

Job description: Research and development in surface and material science, surface and material analysis and characterization using advanced analytical techniques.

GENERAL INFORMATION

Scale of pay:

1. Associate Professor – II: Rs 4500–150–5700 (gross Rs 10,910)
2. Associate Professor – I: Rs 3700–125–4700–150–5000 (gross Rs 9830)
3. Fellow/Scientists – SD: Rs 3000–100–3500–125-4500 (gross Rs 8180)
4. Post-Doctoral Fellow (PDF): Consolidated stipend Rs 4000 per month + Rs 1000 House Rent Subsidy.

Higher starting salary in the scale may be considered in exceptional cases.

All posts are regular except that of PDF which is for one year tenure which may be extended for another term

Age limit: 35 Years in respect of Fellow/Scientist-SD and PDF. Relaxable by 5 years in case of SC/ST candidates.

The above norms may be relaxed in exceptional cases at the discretion of competent authority. Institute offers excellent career opportunities to creative, innovative and result-oriented staff. In addition to pay and allowances, perquisites like Contributory Provident Fund, Gratuity, Medical Facility under its Contributory Health Service Scheme, LTC, Group Linked Insurance Scheme, Subsidised Transport/Conveyance Reimbursement and Subsidized Canteen Facilities are admissible as per Institute rules.

Out-station candidates called for interview will be paid first class to and fro rail/ordinary class bus fare by shortest route in respect of Associate Professor – II & I, Fellow/Scientist-SD and second class fare for PDF on production of proof of journey such as Railway/Bus ticket or ticket No.

How to apply: Typed application on plain paper strictly in the following format with one recent passport size photograph duly affixed on it along with copies of marksheets, experience certificates, testimonials, etc. should reach the Chief Administrative Officer, Institute for Plasma Research at the above address within 20 (twenty) days from the date of publication of this advertisement. **The envelope should be strictly superscribed with Advt No. and Post Applied for.**

Application format

1. Advertisement No.; 2. Post applied for; 3. Name (in block letters); 4. Date of birth; 5. Place of Birth; 6. Age; 7. Marital status; 8. Present address; 9. Permanent address; 10. Whether belongs to SC/ST if so, attach documentary evidence; 11. Qualifications (SSC onwards, indicating a. exam. passed, b. board/university, c. subjects, d. year of passing, e. division, f. percentage of marks obtained); 12. Experience (indicating a. name of the organization, b. nature of work in detail, c. period, d. scale of pay and total salary drawn); 13. References 14. Any other relevant information; 15. Signature with date.

Candidates employed in Govt/quasi Govt/Public Sector undertakings should forward their applications through proper channel. The Institute reserves the right to reject any application without assigning any reason. **Applications not in the above format are liable to be rejected.** No interim correspondence will be entertained.

SUBJECT INDEX

Articles in Commentary, Generalia, Historical commentary and notes, News, Opinion, Research account, Research news; Books reviewed and letters in Correspondence and Scientific correspondence are also listed alphabetically under the respective category name.

Acacia auriculiformis 495 (Scientific correspondence)
Academy document on science education 88 (Correspondence); 89 (Opinion)
Academy Fellowship 969 (Scientific correspondence)
Accelerators 572 (General article)
Acid phosphatase 541 (Research communication)
Active gravitational mass 924 (Research communication)
Adaptive features 587 (Review article)
Aegle marmelos 494 (Scientific correspondence); 932 (Research communication)
Aggressive behaviour 491 (Research news)
AIDS 822 (Introduction, special section); 823, 828, 833, 835, 840, 849, 865 (Articles, special section)
AIDS and tuberculosis 833 (Article, special section)
AIDS, economic analysis 865 (Article, special section)
AIDS, lessons from USA 849 (Article, special section)
Akkulam lake 454 (Research communication)
Albizia lebbek 358 (Research communication)
Alfven, Hannes 73, 74 (Personal news)
Aliphatic-aromatic balance 67 (Research communication)
Alpha-logger 452 (Research communication)
α-turn 434 (Research article)
Ancient gold mining sites 634 (Scientific correspondence)
Animal rights 296 (Article, special section)
Animal welfare 283 (In this issue)
Anomalous cosmic rays 721 (General article)
Anorthosites 21 (Scientific correspondence)
Antihyperglycaemic effects 932 (Research communication)
Anuran acoustic communication 265 (Research communication)
Apple pomace 263 (Research communication)
Applied research 12 (Commentary)
Archaean crust 613 (Research communication)
Armillaria millea 986 (General article)
Artificial satellites 732 (Review article)
Ashtekar program 499 (General article)
Aspergillus flavipes 596 (Research article)
Atmospheric deposition 272 (Research communication)
Autoregulation 178 (Research communication)
Avicennia marina 926 (Research communication)
Axenic culture 21 (Scientific correspondence)
Azolla sp. 97 (Scientific correspondence)

Bacillus sphaericus 695 (Research communication)
Bacillus thuringiensis 939 (Research communication)
Bacterial pathogenesis 1032 (Book review)
Bacterial virulence 965 (Research news)
Bairam–Belkher area 397 (Scientific correspondence)
Basic research 12 (Commentary)
Big bang cosmology 924 (Research communication)
Bilateral outgrowths 771 (Research communication)
Binary pulsar 521 (Review article)
Bioacoustic analysis 265 (Research communication)
Biodiversity 14 (Commentary); 906 (General article)
Biogas inhibition 619 (Research communication)
Biological control 939 (Research communication)
Biological survey 14 (Commentary)
Bioremediation 1028 (Research communication)
Blood transfusion 857 (Article, special section)
Blood viscosity 877 (Research communication)
Bombay offshore 17 (Scientific correspondence)
Bombyx mori 185 (Research communication)

Book reviews
The Action Principle in Physics 368
Annual Review of Biochemistry, Vol. 63, 1994 550
Annual Review of Cell Biology, Vol. 10, 1994 71
Annual Review of Immunology, Vol 13, 1995 945
Annual Review of Medicine, Vol. 46, 1995 946
Annual Review of Neuroscience, Vol. 18 , 1995 626
Annual Review of Phytopathology, Vol. 32, 1994 191
Bacterial Pathogenesis of Plants and Animals: Molecular and Cellular Mechanisms 1032
Beyond the Quantum Paradox 367
Botany in India: History and Progress 371
The Collected Papers of Albert Einstein: Vol. 5 – *The Swiss Years: Correspondence, 1902–1914* 882
Contributions to Operator Theory and its Applications 69
Crustal Evolution of Singhbhum – North Orissa, Eastern India 189
Deep Continental Structure of India: A Review 1031
Development of Ideas in Physics 702
Environment and Adaptive Biology of Plants 72
Ethnobotany and the Search for New Drugs 548
Environmental Health Perspective: Supplements: Molecular Mechanisms of Metal Toxicity and Carcinogenicity 549
Functional Dynamics of Phytophagous Insects 470
The Guide to the Galaxy 189
In vitro Culture and its Applications in Horticulture 277
Laboratory Manual of Organic Chemistry 369
Law, Ethics and HIV: Proceedings of the UNDP Intercountry Consultation 881
Leks 703
Life in Moving Fluids 625
Mahatma Gandhi: An Apostle of Applied Human Ecology 276
A Modern Introduction to Ancient Indian Mathematics: Indian Mathematics and Astronomy 702
Molecular Genetics of Bacterial Pathogenesis 624
Ocean Technology – Perspectives 370
Perspectives in Nematode Physiology and Biochemistry 370
Quark and Jaguar 467
Recent Trends in Aerobiology, Allergy and Immunology 277
Rice Tungro 1994 1031

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

Resonance

journal of science education

Chief Editor
N Mukunda

Resonance is a new monthly journal of science education, designed to enrich learning and teaching of science, particularly at the undergraduate level. The material presented should prove valuable in the assimilation and communication of important concepts and facts, and will include suggestions for experiments and observation. General articles, guest columns, series devoted to specific themes, research news, book reviews, reprinted classics, questions and answers, a teachers' section, poster centre-folds, quotations and anecdotes, and career information will all be included. Each issue will be well-illustrated and have a balanced coverage of different areas of science.

Sample Contents

Origin (?) of the Universe	*J V Narlikar*
The Earth's Changing Climate	*P K Das*
Lasers	*K C Rustagi*
Fermat's Last Theorem	*C S Yogananda*
Geometry	*K Paranjape*
Randomness and Probability	*R L Karandikar*
Fascinating Organic Transformations	*S Ranganathan*
Resonance in Chemistry	*J Chandrasekhar*
Life: Complexity and Diversity	*Madhav Gadgil*
Know your Chromosomes	*Vani Brahmachari*
Honeybee Dance Language	*R Gadagkar*
Teaching Quantum Mechanics	*B M Udgaonkar*
Learning Organic Chemistry through Natural Products	*N R Krishnaswamy*

- *Features:* ● *Molecule of the Month* ● *Nature Watch* ● *What is New in Computers*
- *Research News:* ● *Top Quark Discovery.* ● *Bose-Einstein Condensation*

Published by
Indian Academy of Sciences
Starting January 1996

Annual Subscription Rates

	Personal	Institutional
India	Rs 100	Rs 200
Third World Countries	US $ 25	US $ 50
Other Countries	US $ 50	US $ 100
